$$2KClO_3(s) \longrightarrow 2KCl(s) + 3O_2(g)$$

16. The last step in the production of nitric acid is the reaction of nitrogen dioxide with water.

$$3NO_2(g) + H_2O(l) \longrightarrow 2HNO_3(aq) + NO(g)$$

How many grams of nitrogen dioxide must react with water to produce 5.00×10^{22} molecules of nitrogen monoxide?

Foundations for Math

CONVERSION FACTORS Students often struggle with the proper use of conversion factors. Conversion factors should always be oriented so that like units cancel each other, leaving the desired unit in the numerator. Explain to students that planning the steps of the equation can make the task simpler.

In **Sample Problem 12.5,** the goal is to find the number of molecules of O_2 produced from 29.2 g of H_2O. The necessary equation should end with molecules of O_2 in the numerator of the ratio. With this in mind, students should first look for a molar ratio that is a direct comparison of H_2O and O_2. In this case, the ratio is 2 mol H_2O to 1 mol O_2. Now they know that the first step in their equation is to determine the number of moles in 29.2 g H_2O. Then they can determine the number of moles of O_2 that will be produced and finally the number of molecules of O_2.

DRAW A DIAGRAM On the board or overhead projector, draw a diagram showing the relationships that are useful for solving stoichiometry problems. One simple model reaction is A → B. Use double-headed arrows to connect these terms: *Particles of A, Moles of A, Grams of A, Moles of B, Particles of B,* and *Grams of B*. Above the appropriate arrows, write *Avogadro's number, Coefficients,* and *Molar mass*. Explain that the only "transitions" are allowed between quantities connected by arrows.

Point out that the required conversion factor to make a "transition" is written above each arrow. Encourage students to refer to the diagram when working practice problems.

Explore

Class Activity

PURPOSE Students practice sequencing the steps in solving stoichiometric problems.

MATERIALS 8 white index cards, 1 colored index card, paper punch, 2 brass paper fasteners

PROCEDURE Distribute the white cards to the students. Have them divide the cards into two piles of four cards each. On the first card of the first pile, have them write *Converting a given measured quantity to moles*. On each of the three remaining cards, have students write the conversion factors for converting mass to moles, representative particles to moles, and volume to moles, respectively. For the second set of cards, have students label the first card *Changing moles of wanted substances to a measured quantity.* On each of the remaining cards, have them write the appropriate conversion factor. On the colored card, have students write *Converting moles of given to moles of wanted using mole ratio from balanced chemical equation b mol W/a mol G.* Have the students use the paper punch to punch each of the two sets of cards. Then have them fasten each set with a brass paper fastener. Allow students to practice using the cards to solve the Practice Problems.

EXPECTED OUTCOME The cards should aid in sequencing the steps in solving stoichiometric problems.

Sample Practice Problem

Ammonia (NH_3) reacts with oxygen (O_2) to produce nitrogen monoxide (NO) and water.

$$4NH_3(g) + 5O_2(g) \rightarrow 4NO(g) + 6H_2O(l)$$

How many liters of NO are produced when 1.40 L of oxygen reacts with ammonia? *(1.12 L)*

SampleProblem 12.6

Volume-Volume Stoichiometric Calculations

Nitrogen monoxide and oxygen gas combine to form the brown gas nitrogen dioxide, which contributes to photochemical smog. How many liters of nitrogen dioxide are produced when 34 L of oxygen react with an excess of nitrogen monoxide? Assume conditions are at STP.

$$2NO(g) + O_2(g) \longrightarrow 2NO_2(g)$$

1 Analyze **List the knowns and the unknown.**

The following calculations need to be performed:

$$L\ O_2 \longrightarrow mol\ O_2 \longrightarrow mol\ NO_2 \longrightarrow L\ NO_2$$

For gaseous reactants and products at STP, 1 mol of a gas has a volume of 22.4 L.

KNOWNS

volume of oxygen = 34 L O_2
2 mol NO_2/1 mol O_2 (from balanced equation)
1 mol O_2 = 22.4 L O_2 (at STP)
1 mol NO_2 = 22.4 L NO_2 (at STP)

UNKNOWN

volume of nitrogen dioxide = ? L NO_2

2 Calculate **Solve for the unknown.**

Start with the given quantity, and convert from volume to moles by using the mole-volume ratio.

$$34\ \cancel{L\ O_2} \times \frac{1\ mol\ O_2}{22.4\ \cancel{L\ O_2}}$$

Next, convert from moles of reactant to moles of product by using the balanced chemical equation mole ratio.

$$34\ \cancel{L\ O_2} \times \frac{1\ \cancel{mol\ O_2}}{22.4\ \cancel{L\ O_2}} \times \frac{2\ mol\ NO_2}{1\ \cancel{mol\ O_2}}$$

Finally, convert from moles to liters. Use the mole-volume ratio.

$$34\ \cancel{L\ O_2} \times \frac{1\ \cancel{mol\ O_2}}{22.4\ \cancel{L\ O_2}} \times \frac{2\ \cancel{mol\ NO_2}}{1\ \cancel{mol\ O_2}} \times \frac{22.4\ L\ NO_2}{1\ \cancel{mol\ NO_2}} = 68\ L\ NO_2$$

Given quantity | Change to moles | Mole ratio | Change to liters

3 Evaluate **Does the result make sense?** Because 2 mol NO_2 are produced for each 1 mol O_2 that reacts, the volume of NO_2 should be twice the given volume of O_2. The answer should have two significant figures.

17. The equation for the combustion of carbon monoxide is

$$2CO(g) + O_2(g) \longrightarrow 2CO_2(g)$$

How many liters of oxygen are required to burn 3.86 L of carbon monoxide?

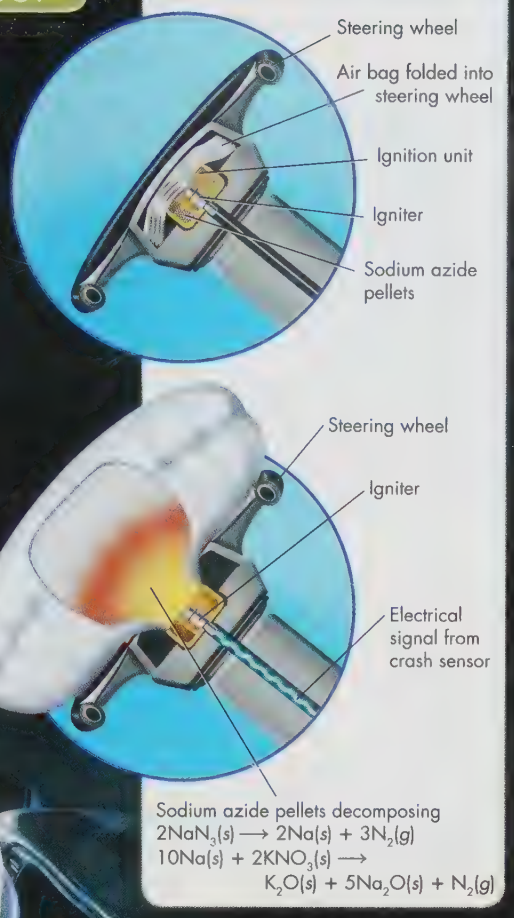
18. Phosphorus and hydrogen can be combined to form phosphine (PH_3).

$$P_4(s) + 6H_2(g) \longrightarrow 4PH_3(g)$$

How many liters of phosphine are formed when 0.42 L of hydrogen reacts with phosphorus?

Differentiated Instruction

L1 STRUGGLING STUDENTS Encourage students to find a method of problem solving that capitalizes on their strengths, such as drawing pictures of reactants and products. Make molecular model kits available to help students visualize reactions.



LPR LESS PROFICIENT READERS Direct students' attention to the key questions and answers. Rewrite the answers on the board, and then revise them by writing simplified sentences or bulleted lists.

L3 ADVANCED STUDENTS Have computer-literate students use the calculations in the sample problem as the basis for a general algorithm in a spreadsheet or computer program to solve stoichiometric problems. Have students demonstrate and explain their programs to interested classmates.

Stoichiometric Safety

In a car collision, proper inflation of an air bag may save your life. Too much air in the bag could make the bag too hard, which could cause injury because the bag wouldn't effectively cushion the blow. Too little air in the bag could be insufficient to prevent a driver's impact with the steering wheel. Engineers use stoichiometry to determine the exact quantity of each reactant in the air bag's inflation system.

When a crash occurs, a series of reactions happen. Sodium azide (NaN_3) decomposes into sodium metal and nitrogen gas. The nitrogen gas causes the air bag to inflate, but the sodium can react explosively with water. So, air bags contain potassium nitrate (KNO_3) to react with the sodium. Silicon dioxide is also included in the air bag to react with the products of the second reaction. This final reaction produces a harmless substance.

CRASH TEST Air bag performance is tested using a crash test dummy. The production of nitrogen gas causes air bags to erupt from their storage site at speeds up to 200 miles per hour.

Take It Further

1. Draw Conclusions If a reaction in an air bag does not occur as intended, how might this affect the performance of an air bag?

2. Explain Research the regulations on automotive air bags, and explain why air bags are not safe for all passengers.

21st Century Learning To be successful in the 21st century, students need skills and learning experiences that extend beyond subject matter mastery. The following project helps students build 21st Century Skills.

BROADCASTING FOR SAFETY Pose the following challenge to students: *A major broadcasting corporation is creating a new automotive-themed podcast and has hired you as its host. Form groups of four to five students to do the following:*

- Write, produce, and record a 35-40 minute podcast, with one student serving as the host, one as an expert on air bag restraint systems, and two to three students as callers to the show.
- The show host will conduct a 20-minute interview with the expert, eliciting important information about current air bag technologies and those in development for future car models.
- The callers will use the final 15-20 minutes of the show to ask questions about safety and environmental concerns. The podcast will be submitted as an MP3 file either via e-mail or on a CD or DVD.

CHEMISTRY & YOU Write the following reactions on the board.

Reaction I $2NaN_3(s) \rightarrow 2Na(s) + 3N_2(g)$

Reaction II $10Na(s) + 2KNO_3(s) \rightarrow K_2O(s) + 5Na_2O(s) + N_2(g) + \text{heat}$

Point out that the proper inflation of the air bag requires two reactions. Explain that an electrical current produced by the igniter causes the decomposition of sodium azide into sodium metal and nitrogen gas. Note that the sodium metal produced is dangerously reactive. In a second reaction, potassium nitrate reacts with the elemental sodium and forms potassium oxide, sodium oxide, and additional nitrogen gas. The heat causes all the solid products to fuse with SiO_2, powdered sand, which is also part of the reaction mixture. The fused product is a safe, unreactive glass.

Ask How many moles of potassium nitrate must be included in the reaction mixture to consume the sodium produced by the decomposition of one mole of sodium azide? *(0.2 mol KNO_3)* **Ask** How many liters of N_2 are produced at STP if 1.0 mole of sodium azide and 0.20 mole of potassium nitrate react? *(36 L)*

Have students speculate how the pressure of the gas inside the air bag depends on the number of moles of nitrogen produced and the temperature inside the air bag. *(Acceptable answers should indicate that because gas pressure depends on the number of gas particles present, pressure depends on the number of moles of gas particles present. The heat released by this reaction raises the temperature of the gaseous products, helping the bag inflate even faster.)*

Extend

Connect to LANGUAGE ARTS

Explain to students that the use of air bag restraint systems (seatbelt/air bags) reduces the risk of fatalities in accidents by about 70%. However, not all passengers in a vehicle benefit from air bags, which can deliver a significant blow to a passenger when activated. Have students research the injuries that can occur as the result of air bag deployment, then have students write an argumentative essay that advocates the use of air bags despite the potential for injury. Essays should include current recommendations and restrictions for the use of air bags with small children and infants.

Answers

17. 1.93 L O_2

18. 0.28 L PH_3

TAKE IT FURTHER

1. Answers will vary. The air bag could under inflate or inflate too slowly.
2. Answers will vary. Some students may find that passenger-side air bags are not safe for young children.

Evaluate

Informal Assessment

Write a balanced equation on the board, such as $H_2(g) + I_2(g) \rightarrow 2HI(g)$. Have students orally state all the different mole ratios for the reaction; write all of the given ratios on the board. Then pose a problem, such as, *How many moles of hydrogen iodide are formed when 0.75 mol I_2 gas is reacted with excess hydrogen gas*? Have students go to the board and place their initials next to the correct mole ratio for the problem. Repeat with various types of reactions. Then have students complete the 12.2 Lesson Check.

Reteach

Use molecular models to review the importance of mole ratios. Illustrate how the mole ratios from the balanced chemical equation are related to the individual atoms, formula units, and molecules of the reactants and products as described by the equation.

Sample Problem 12.7

Finding the Volume of a Gas Needed for a Reaction

Assuming STP, how many milliliters of oxygen are needed to produce 20.4 mL SO_3 according to this balanced equation?

$$2SO_2(g) + O_2(g) \longrightarrow 2SO_3(g)$$

1 Analyze **List the knowns and the unknown.** For a reaction involving gaseous reactants or products, the coefficients also indicate relative amounts of each gas. So, you can use volume ratios in the same way you have used mole ratios.

KNOWNS

volume of sulfur trioxide = 20.4 mL

1 ml O_2/2 ml SO_3 (from balanced equation)

UNKNOWN

volume of oxygen = ? mL O_2

2 Calculate **Solve for the unknown.**

Multiply the given volume by the appropriate volume ratio.

$$20.4 \text{ mL } SO_3 \times \frac{1 \text{ mL } O_2}{2 \text{ mL } SO_3} = 10.2 \text{ mL } O_2$$

The volume ratio can be written using milliliters as the units instead of liters.

3 Evaluate **Does the result make sense?** Because the volume ratio is 2 volumes SO_3 to 1 volume O_2, the volume of O_2 should be half the volume of SO_3. The answer should have three significant figures.

Use the following chemical equation to answer Problems 19 and 20.

$$CS_2(l) + 3O_2(g) \longrightarrow CO_2(g) + 2SO_2(g)$$

19. Calculate the volume of sulfur dioxide, in milliliters, produced when 27.9 mL O_2 reacts with carbon disulfide.

20. How many deciliters of carbon dioxide are produced when 0.38 L SO_2 is formed?

12.2 LessonCheck

21. **Explain** How are mole ratios used in chemical calculations?

22. **Sequence** Outline the sequence of steps needed to solve a typical stoichiometric problem.

23. **Calculate** The combustion of acetylene gas is represented by this equation:

$$2C_2H_2(g) + 5O_2(g) \longrightarrow 4CO_2(g) + 2H_2O(g)$$

a. How many grams of CO_2 and grams of H_2O are produced when 52.0 g C_2H_2 burn in oxygen?

b. How many moles of H_2O are produced when 64.0 g C_2H_2 burn in oxygen?

24. **Apply Concepts** Write the 12 mole ratios that can be derived from the equation for the combustion of isopropyl alcohol.

$$2C_3H_7OH(l) + 9O_2(g) \longrightarrow 6CO_2(g) + 8H_2O(g)$$

BIG IDEA

THE MOLE AND QUANTIFYING MATTER

25. Use what you have learned about stoichiometric calculations to explain the following statement: Stoichiometric calculations are not possible without a balanced chemical equation.

Lesson Check Answers

21. Mole ratios are written using the coefficients from a balanced chemical equation. They are used to relate moles of reactants and products in stoichiometric calculations.

22. Convert the given quantity to moles; use the mole ratio from the equations to find the moles of the wanted; convert moles of wanted to the desired unit.

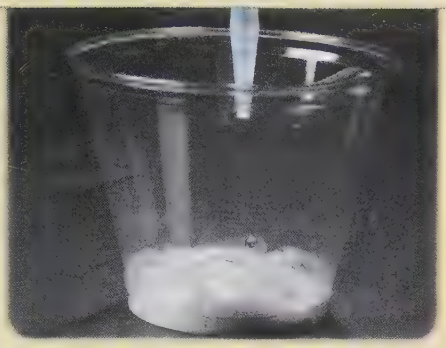
23. **a.** 176 g CO_2, 36.0 g H_2O **b.** 2.46 mol H_2O

24. $\frac{2 \text{ mol } C_3H_7OH}{9 \text{ mol } O_2}$ $\frac{2 \text{ mol } C_3H_7OH}{6 \text{ mol } CO_2}$ $\frac{2 \text{ mol } C_3H_7OH}{8 \text{ mol } H_2O}$ $\frac{9 \text{ mol } O_2}{6 \text{ mol } CO_2}$ $\frac{9 \text{ mol } O_2}{8 \text{ mol } H_2O}$ $\frac{6 \text{ mol } CO_2}{8 \text{ mol } H_2O}$

$\frac{9 \text{ mol } O_2}{2 \text{ mol } C_3H_7OH}$ $\frac{6 \text{ mol } CO_2}{2 \text{ mol } C_3H_7OH}$ $\frac{8 \text{ mol } H_2O}{2 \text{ mol } C_3H_7OH}$ $\frac{6 \text{ mol } CO_2}{9 \text{ mol } O_2}$ $\frac{8 \text{ mol } H_2O}{9 \text{ mol } O_2}$ $\frac{8 \text{ mol } H_2O}{6 \text{ mol } CO_2}$

25. A chemical reaction's mole ratios are derived from the relationships between coefficients in a balanced chemical equation.

Small-Scale Lab



Analysis of Baking Soda

Purpose

To determine the mass of sodium hydrogen carbonate in a sample of baking soda, using stoichiometry

Materials

- baking soda
- 3 plastic cups
- soda straw
- balance
- pipets of HCl, NaOH, and thymol blue
- pH sensor (optional)

Procedure

A. Measure the mass of a clean, dry plastic cup.

B. Using the straw as a scoop, fill one end with baking soda to a depth of about 1 cm. Add the sample to the cup and measure its mass again.

C. Place two HCl pipets that are about 3/4 full into a clean cup and measure the mass of the system.

D. Transfer the contents of both HCl pipets to the cup containing baking soda. Swirl until the fizzing stops. Wait 5–10 minutes to be sure the reaction is complete. Measure the mass of the two empty HCl pipets in their cup again.

E. Add 5 drops of thymol blue to the plastic cup.

F. Place two full NaOH pipets in a clean cup and measure the mass of the system.

G. Add NaOH slowly to the baking soda/HCl mixture until the pink color just disappears. Measure the mass of the NaOH pipets in their cup again.

Analyze

Using your experimental data, record the answers to the following questions below your data table.

1. Evaluate Write a balanced equation for the reaction between baking soda ($NaHCO_3$) and HCl.

2. Calculate Calculate the mass in grams of the baking soda.

(Step B − Step A)

3. Calculate Calculate the total mmol of 1*M* HCl. *Note:* Every gram of HCl contains 1 mmol.

(Step C − Step D) × 1.00 mmol/g

4. Calculate Calculate the total mmol of 0.5*M* NaOH. *Note:* Every gram of NaOH contains 0.5 mmol.

(Step F − Step G) × 0.500 mmol/g

5. Calculate Calculate the mmol of HCl that reacted with the baking soda. *Note:* The NaOH measures the amount of HCl that did not react.

(Step 3 − Step 4)

6. Calculate Calculate the mass of the baking soda from the reaction data.

(0.084 g/mmol × Step 5)

7. Calculate Calculate the percent error of the experiment.

$$\frac{(\text{Step 2} - \text{Step 6})}{\text{Step 2}} \times 100\%$$

You're the Chemist

The following small-scale activities allow you to develop your own procedures and analyze the results.

1. Analyze Data For each calculation you did, substitute each quantity (number and unit) into the equation and cancel the units to explain why each step gives the quantity desired.

2. Design an Experiment Baking powder consists of a mixture of baking soda, sodium hydrogen carbonate, and a solid acid, usually calcium dihydrogen phosphate ($Ca(H_2PO_4)_2$). Design and carry out an experiment to determine the percentage of baking soda in baking powder.

ANALYZE

1. $HCl + NaHCO_3(s) \rightarrow CO_2(g) + H_2O + NaCl$
2. 3.28 g – 2.83 g = 0.45 g
3. (10.70 – 4.29) g × 1.00 mmol/g = 6.41 mmol
4. (10.53 – 8.78) g × 0.500 mmol/g = 0.875 mmol (0.875 mmol HCl unreacted)
5. 6.41 mmol total – 0.875 mmol unreacted = 5.54 mmol (5.54 mmol $NaHCO_3$)
6. (0.0840 g/mmol) × 5.53 mmol = 0.46 g
7. (0.46 – 0.45) g/0.45 g × 100% = 2% error (assuming baking soda is one hundred percent sodium hydrogen carbonate)

YOU'RE THE CHEMIST

1. See Steps 2–7.
2. Repeat Steps A–G and 1–7 using baking powder instead of baking soda. The percent error is the percent of baking soda in baking powder, assuming no other errors.

FOR ENRICHMENT Ask students to predict how much baking soda and 1 *M* HCl are needed to produce enough CO_2 to fill a 1-L plastic bag. Have them write a procedure and then carry out the experiment.

Explore

Small-Scale Lab

OBJECTIVE Students calculate the mass of $NaHCO_3$ in a sample using stoichiometry.

PREP TIME 1 hour

CLASS TIME 30 minutes

MATERIALS Baking soda; plastic cups; soda straws; mass balances; pipets of HCl, NaOH, and thymol blue; pH sensor (optional)

ADVANCE PREP

Solution	Preparation
0.5*M* NaOH	20.0 g in 1.0 L
1.0*M* HCl	82 mL of 12*M* in 1.0 L
	Caution *Always add acid to water carefully and slowly.*
0.04% TB	100 mg in 21.5 mL
	of 0.01*M* NaOH; dilute to 250 mL

SAFETY Have students wear safety glasses and follow the standard safety procedures.

TEACHING TIPS

- Stress that the procedure measures the amount of excess HCl that is not reacted with the baking soda (Step 4). Because this excess HCl reacts with the NaOH in a 1:1 mole ratio, the moles of NaOH equal the moles of HCl in excess. Subtracting the excess moles of HCl from the total moles used in the experiment (Step 5) yields the moles reacted with the baking soda, which is 100% $NaHCO_3$.
- If the mixture does not turn red when thymol blue is added, the student should find the mass of a third pipet and add just enough HCl to turn the mixture cherry red. Then the student should find the mass of the half-empty pipet so the mass of HCl added can be calculated and added to the total mass used.

EXPECTED OUTCOME Sample data: Step A. 2.83 g, B. 3.28 g, C. 10.70 g, D. 4.29 g, F. 10.53 g, G. 8.78 g

Answers

19. 18.6 mL SO_2

20. 1.9 dL CO_2

LESSON 12.3

Key Objectives

12.3.1 EXPLAIN how the amount of product in a reaction is affected by an insufficient quantity of any of the reactants.

12.3.2 EXPLAIN what the percent yield of a reaction measures.

Additional Resources

- Reading and Study Workbook, Lesson 12.3
- Teaching Resources, Lesson 12.3
- Laboratory Manual, Lab 20

PearsonChem.com

Engage

CHEMISTRY & YOU Direct students to the photograph at the beginning of the lesson. **Ask** If you have two tabletops and seven table legs and you want to construct built-in tables using two legs for support of each table, what part limits the number of tables you can construct? *(tabletops)* **Ask** How many unused parts would remain? *(3 legs)*

Build Background

Have students think about the yield information in their favorite cookie recipes. **Ask** Do you always get the number of cookies your recipe supposedly yields when you bake a batch? *(no)* **Ask** What affects the number of cookies in a batch? *(Sample answers: inaccurate measurements, size of cookies, an ingredient left out)* Tell students to keep this example in mind as they work through the lesson.

IN ACADEMIC STANDARDS for SCIENCE

- Apply standard techniques in laboratory investigations to measure physical quantities in appropriate units and convert known quantities to other units as necessary.

C.4.2 Balance chemical equations using the law of conservation of mass and use them to describe chemical reactions.

C.5.3 Given the equation for a chemical reaction involving one or more gases as reactants and/or products, calculate the volumes of gas assuming the reaction goes to completion and the ideal gas law holds.

Also covered C.4.3, C.4.4

12.3 Limiting Reagent and Percent Yield

C.4.3 The mole concept; C.4.4 Calculate reactants and products; C.5.3 Reactant and product calculations: gases

CHEMISTRY & YOU

Q: *What determines how much product you can make?* If a carpenter had two tabletops and seven table legs, he would have difficulty building more than one functional four-legged table. The first table would require four of the legs, leaving just three legs for the second table. In this case, the number of table legs is limiting the construction of four-legged tables. In this lesson you will learn how the amount of product is limited in a chemical reaction.

Key Questions

How is the amount of product in a reaction affected by an insufficient quantity of any of the reactants?

What does the percent yield of a reaction measure?

Vocabulary

- limiting reagent
- excess reagent
- theoretical yield
- actual yield
- percent yield

Limiting and Excess Reagents

How is the amount of product in a reaction affected by an insufficient quantity of any of the reactants?

Many cooks follow a recipe when making a new dish. They know that sufficient quantities of all the ingredients must be available in order to follow the recipe. Suppose, for example, that you are preparing to make tacos like the ones in Figure 12.6. You would have more than enough meat, cheese, lettuce, tomatoes, sour cream, salsa, and seasoning on hand. However, you have only two taco shells. The quantity of taco shells you have will limit the number of tacos you can make. Thus, the taco shells are the limiting ingredient in this cooking venture. A chemist often faces a similar situation. **In a chemical reaction, an insufficient quantity of any of the reactants will limit the amount of product that forms.**

Figure 12.6 Limiting Ingredients
The amount of product is determined by the quantity of the limiting reagent. In this example, the taco shells are the limiting reagent. No matter how much of the other ingredients you have, with two taco shells you can make only two tacos.

Focus on ELL

1 CONTENT AND LANGUAGE Direct students' attention to the word *reagent* in the lesson title, and tell students that it is derived from the Latin word for "react." Explain that reagents are substances that chemically react with other substances to form new substances, so a reagent is a reactant in a chemical equation.

2 FRONTLOAD THE LESSON Ask students to think about items that need to be assembled by the purchaser, such as furniture or models sold as kits. Point out that even though materials lists in these kits state that each kit contains enough parts to complete the item, some kits may be missing parts and some may have extra parts. Ask volunteers to share their experiences with such items.

3 COMPREHENSIBLE INPUT Use ball-and-stick models to demonstrate the concepts illustrated in Figure 12.7. Say and write instructions when demonstrating the sample problems.

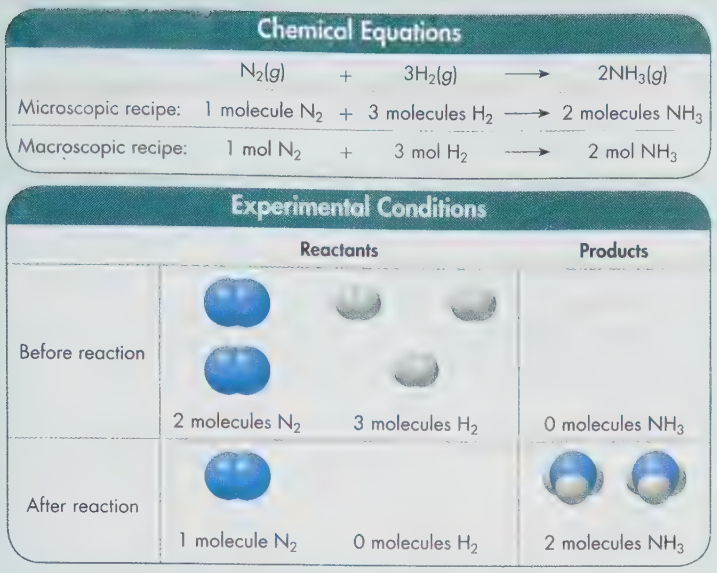


Figure 12.7 Limiting Reagent The "recipe" calls for three molecules of H_2 for every one molecule of N_2.

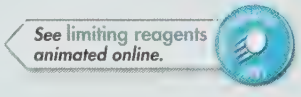
In this particular experiment, H_2 is the limiting reagent and N_2 is in excess.
Infer *How would the amount of products formed change if you started with four molecules of N_2 and three molecules of H_2?*

As you know, a balanced chemical equation is a chemist's recipe. You can interpret the recipe on a microscopic scale (interacting particles) or on a macroscopic scale (interacting moles). The coefficients used to write the balanced equation give both the ratio of representative particles and the mole ratio. Recall the equation for the preparation of ammonia:



$$N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$$

When one molecule (mole) of N_2 reacts with three molecules (moles) of H_2, two molecules (moles) of NH_3 are produced. What would happen if two molecules (moles) of N_2 reacted with three molecules (moles) of H_2? Would more than two molecules (moles) of NH_3 be formed? Figure 12.7 shows both the particle and the mole interpretations of this problem.

Before the reaction takes place, nitrogen and hydrogen are present in a 2:3 molecule (mole) ratio. The reaction takes place according to the balanced equation. One molecule (mole) of N_2 reacts with three molecules (moles) of H_2 to produce two molecules (moles) of NH_3. At this point, all the hydrogen has been used up, and the reaction stops. One molecule (mole) of unreacted nitrogen is left in addition to the two molecules (moles) of NH_3 that have been produced by the reaction.

In this reaction, only the hydrogen is completely used up. This reactant is the **limiting reagent**, or the reactant that determines the amount of product that can be formed by a reaction. The reaction occurs only until the limiting reagent is used up. By contrast, the reactant that is not completely used up in a reaction is called the **excess reagent**. In this example, nitrogen is the excess reagent because some nitrogen remains unreacted.

Sometimes in stoichiometric problems, the given quantities of reactants are expressed in units other than moles. In such cases, the first step in the solution is to convert the quantity of each reactant to moles. Then the limiting reagent can be identified. The amount of product formed in a reaction can be determined from the given amount of limiting reagent.

CHEMISTRY & YOU

Q: *What determines how much product you can make in a chemical reaction?*

Differentiated Instruction

LPR LESS PROFICIENT READERS Help students understand the concept of a limiting reagent by comparing it to everyday situations. For example, suppose a person is planning a dinner party. He has 6 glasses, 8 plates, and 4 chairs. How many people can he invite? Or, you might ask, how many party invitations can you send if you have 24 invitations, 12 envelopes, and 10 stamps?

ELL ENGLISH LANGUAGE LEARNERS Discuss with students the meaning of the word *reagent*. Ask them to define *reagent* in their own words. Then ask students to define the words *limit* and *excess* in their own words. Then ask students to state the meanings of *limiting reagent* and *excess reagent* in their own words.

READING STRATEGY Have students quickly read through the lesson and use context clues to help define the meaning of *limiting reagent* and *excess reagent*. Discuss real-world meanings of the terms *limiting* and *excess*.

Explain

Limiting and Excess Reagents

USING VISUALS Direct students' attention to Figure 12.6. **Ask** Where else do you see examples of processes or activities being "limited" on an everyday basis? *(Sample answers: the number of people you can fit into a car and the number of biscuits that can be made with one cup of flour)*

Explore

Teacher Demo

PURPOSE Students model the concept of a limiting reagent.

MATERIALS 15 plastic bottles, 30 plastic caps to fit the bottles, 6 containers to hold 5 caps each

PROCEDURE Before the demonstration, place five caps in each container and put them out of the sight of the students. Set out all 15 plastic bottles. Bring out one container of caps. **Ask** How many closed plastic bottles can we have? *(5)* **Ask** What limits the number? (*caps*) Bring out another container of caps. Again, ask the students what will happen. Continue bringing out caps and matching them to the bottles.

EXPECTED OUTCOME With two containers of caps, students should indicate that the caps are the limiting factor. With three containers, students should realize that there is a one-to-one correspondence and therefore no limiting factor. Students may also argue that both the bottles and caps are equally limiting factors. With the remaining containers, the caps are in excess and students should indicate that the bottles are the limiting factor.

CHEMISTRY & YOU the limiting reagent

Answers

FIGURE 12.7: The amount would remain the same; two molecules of NH_3 would form.

Explain

APPLY CONCEPTS Write the balanced chemical equation for the following reaction on the board: $2Na(s) + Cl_2(g) \rightarrow 2NaCl(s)$. Ask a series of questions that require students to predict the amount of product formed, based on molar quantities of reactant supplied by you. Be sure to use small whole numbers that students can easily manipulate without calculators. As students solve the problems, record the molar quantities under each reactant and product in the equation. Point out how these values are related for each set of conditions. In each case, ask students to state which reactant is the limiting reagent and circle the value in the list to designate it as the limiting quantity.

Misconception Alert

Caution students not to make quick judgments when finding the limiting reagent in a reaction. Often, students make a decision based on mass, or they do not completely finish the calculation and answer prematurely. Encourage students to read a problem slowly, formulate a plan, and write each calculation in steps until a final answer is obtained. Emphasize the importance of checking the reasonableness of an answer.

Sample Practice Problem

Phosphoric acid reacts with sodium hydroxide according to the following equation:

$$H_3PO_4(aq) + 3NaOH(aq) \rightarrow Na_3PO_4(aq) + 3H_2O(l)$$

If 1.75 mol H_3PO_4 is made to react with 5.00 mol NaOH, what is the limiting reagent? *(5.25 mol NaOH is required; NaOH is the limiting reagent.)*

SampleProblem 12.8

Determining the Limiting Reagent in a Reaction

Copper reacts with sulfur to form copper(I) sulfide according to the following balanced equation:

$$2Cu(s) + S(s) \longrightarrow Cu_2S(s)$$

What is the limiting reagent when 80.0 g Cu reacts with 25.0 g S?

1 Analyze **List the knowns and the unknown.** The number of moles of each reactant must first be found. The balanced equation is used to calculate the number of moles of one reactant needed to react with the given amount of the other reactant.

KNOWNS
mass of copper = 80.0 g Cu
mass of sulfur = 25.0 g S
1 mol S / 2 mol Cu

UNKNOWN
limiting reagent = ?

2 Calculate **Solve for the unknown.**

Start with one of the reactants and convert from mass to moles.

$$80.0\,\text{g Cu} \times \frac{1\,\text{mol Cu}}{63.5\,\text{g Cu}} = 1.26\,\text{mol Cu}$$

Then, convert the mass of the other reactant to moles.

$$25.0\,\text{g S} \times \frac{1\,\text{mol S}}{32.1\,\text{g S}} = 0.779\,\text{mol S}$$

Now convert moles of Cu to moles of S needed to react with 1.26 moles of Cu.

$$1.26\,\text{mol Cu} \times \frac{1\,\text{mol S}}{2\,\text{mol Cu}} = 0.630\,\text{mol S}$$

Given quantity | Mole ratio | Needed amount

Compare the amount of sulfur needed with the given amount of sulfur.

0.630 mol S (amount needed to react) < 0.779 mol S (given amount)
Sulfur is in excess, so copper is the limiting reagent.

It doesn't matter which reactant you use. If you used the actual number of moles of S to find the amount of copper needed, then you would still identify copper as the limiting reagent.

3 Evaluate **Do the results make sense?** Since the ratio of the given mol Cu to mol S was less than the ratio (2:1) from the balanced equation, copper should be the limiting reagent.

26. The equation for the complete combustion of ethene (C_2H_4) is

$$C_2H_4(g) + 3O_2(g) \longrightarrow 2CO_2(g) + 2H_2O(g)$$

If 2.70 mol C_2H_4 reacts with 6.30 mol O_2, identify the limiting reagent.

27. Hydrogen gas can be produced by the reaction of magnesium metal with hydrochloric acid.

$$Mg(s) + 2HCl(aq) \longrightarrow MgCl_2(aq) + H_2(g)$$

Identify the limiting reagent when 6.00 g HCl reacts with 5.00 g Mg.

Differentiated Instruction

L1 SPECIAL NEEDS Modify the sample problems so you can explain the concepts of limiting reagents and excess reagents by using manipulatives, such as coins, chips, or food items. These visual representations will engage students' senses and allow them to experience the concepts.

ELL ENGLISH LANGUAGE LEARNERS Label a number line from 0 to 1 by increments of 0.1. Using the overhead projector, plot the number of moles calculated for sulfur in **Sample Problem 12.8** on the number line to show students that 0.779 > 0.630. Encourage students to use number lines when determining which number is greater.

In Sample Problem 12.8, you may have noticed that even though the mass of copper used in the reaction is greater than the mass of sulfur, copper is the limiting reagent. The reactant that is present in the smaller amount by mass or volume is not necessarily the limiting reagent.

Sample Problem 12.9

Using a Limiting Reagent to Find the Quantity of a Product

What is the maximum number of grams of Cu_2S that can be formed when 80.0 g Cu reacts with 25.0 g S?

$$2Cu(s) + S(s) \longrightarrow Cu_2S(s)$$

1 Analyze **List the knowns and the unknown.**
The limiting reagent, which was determined in Sample Problem 12.8, is used to calculate the maximum amount of Cu_2S formed.

$$\text{mol Cu} \longrightarrow \text{mol } Cu_2S \longrightarrow \text{g } Cu_2S$$

KNOWNS
limiting reagent = 1.26 mol Cu (from sample problem 12.8)
1 mol Cu_2S = 159.1 g Cu_2S (molar mass)
1 mol Cu_2S / 2 mol Cu (from balanced equation)

UNKNOWN
yield = ? g Cu_2S

2 Calculate **Solve for the unknown.**

Start with the moles of the limiting reagent and convert to moles of the product. Use the mole ratio from the balanced equation.

$$1.26 \text{ mol Cu} \times \frac{1 \text{ mol } Cu_2S}{2 \text{ mol Cu}}$$

Finish the calculation by converting [illegible] to grams of product.

$$1.26 \text{ mol Cu} \times \frac{1 \text{ mol } Cu_2S}{2 \text{ mol Cu}} \times \frac{159.1 \text{ g } Cu_2S}{1 \text{ mol } Cu_2S} = 1.00 \times 10^2 \text{ g } Cu_2S$$

3 Evaluate **Do the results make sense?** Copper is the limiting reagent in this reaction. The maximum number of grams of Cu_2S produced should be more than the amount of copper that initially reacted because copper is combining with sulfur. However, the mass of Cu_2S produced should be less than the total mass of the reactants (105.0 g) because sulfur was in excess.

28. The equation below shows the incomplete combustion of ethene.

$$C_2H_4(g) + 2O_2(g) \longrightarrow 2CO(g) + 2H_2O(g)$$

If 2.70 mol C_2H_4 is reacted with 6.30 mol O_2,
a. identify the limiting reagent.
b. calculate the moles of water produced.

29. The heat from an acetylene torch is produced by burning acetylene (C_2H_2) in oxygen.

$$2C_2H_2(g) + 5O_2(g) \longrightarrow 4CO_2(g) + 2H_2O(g)$$

How many grams of water can be produced by the reaction of 2.40 mol C_2H_2 with 7.40 mol O_2?

Foundations for Math

SCIENTIFIC NOTATION Explain that it is typical for very large and very small numbers to be written in scientific notation, simply for the ease of writing or stating the number. For example, it is cumbersome for a scientist to write the number 0.0000000000082 and much simpler to write 8.2×10^{-12}.

The number 8.2×10^{-12} is basically the product of a decimal coefficient, 8.2, and an exponential term, 10^{-12}. The decimal coefficient is ≥ 1 and < 10. It also indicates the number of significant figures in a measurement. The exponent indicates the placement of the decimal point. A **positive** exponent indicates to move the decimal point that number of places to the right. A **negative** exponent indicates to move the decimal point that number of places to the left.

The measure 3,440,000 cm can be written as 3.44×10^6 cm. This measure has 3 significant figures, whereas 0.00047 cm = 4.7×10^{-4} cm has only 2 significant figures.

Explore

Class Activity

PURPOSE Students will use simple molecular models to demonstrate the concept of a limiting reagent in a chemical reaction.

PREP TIME 5 minutes

CLASS TIME 15 minutes

MATERIALS 20 metal paper clips (symbol M), 20 same-colored vinyl-coated paper clips (symbol C), plastic sandwich bag

PROCEDURE

1. Link two paper clips of the same type several times to form models representing 10 diatomic molecules of each reactant. Place these molecules in the plastic bag.
2. Without looking, remove 15 molecules from the plastic bag.
3. Line up the M_2 and C_2 molecules in two adjacent vertical rows.
4. Pair reactant molecules in the 1:3 M_2-to-C_2 ratio as shown in the equation $M_2 + 3C_2 \rightarrow 2MC_3$.
5. Make the molecules "react" by taking pairs of clips apart and forming two molecules of the product.
6. Continue making M_2 and C_2 react in a 1:3 ratio until you run out of one of the reactants.

THINK ABOUT IT

1. List the number of each type of reactant molecule that you removed from the bag. *(Answers may vary.)*
2. How many molecules of the product did you form? *(Answers may vary: It depends on n_{M_2} and n_{C_2}.)*
3. Which reactant molecule did you run out of first? *(Answers may vary: It depends on n_{M_2} and n_{C_2}.)*
4. How many molecules of each reactant remained at the completion of the reaction? *(Answers may vary: It depends on n_{M_2} and n_{C_2}.)*
5. Repeat the experiment and compare the results. *(Sample answer: The number of MC_3 molecules formed and the number and type of reactant molecules remaining depend on the initial number of M_2 and C_2 molecules and the ratio of M to C atoms in the molecular formula.)*

Answers

26. O_2 is the limiting reagent.
27. HCl is the limiting reagent.
28. **a.** 5.40 mol O_2 is required; C_2H_4 is the limiting reactant.
b. 5.40 mol H_2O
29. 43.2 g H_2O

Explore

QuickLab

OBJECTIVE Students observe the effect that changing the amount of limiting reagent in a reaction has on the amounts of products.

SKILLS FOCUS Observing, measuring, calculating

PREP TIME 15 minutes

CLASS TIME 20 minutes

MATERIALS graduated cylinders, mass balances, 250-mL Erlenmeyer flasks, rubber balloons, magnesium ribbons, 1.0*M* hydrochloric acid

SAFETY The balloons contain hydrogen gas and should be kept away from heat and open flames during and after the experiment. Caution students about the corrosive nature of HCl. Students should wear safety glasses and aprons. Once the reaction in a flask is complete, carefully remove the balloon. Disperse the gas in a fume hood or outside. Neutralize remaining HCl(*aq*) with baking soda before flushing down the drain.

TEACHING TIPS Have students carefully balance the equation for the reaction and then look at the mole ratio from the balanced equation and the molar amounts of the two reactants present before they make their prediction in Step 4.

EXPECTED OUTCOME The approximate volumes of the balloons are 0.60 g Mg, 0.5 L H_2; 1.2 g Mg, 1 L H_2; 2.4 g Mg, 1 L H_2.

ANALYZE AND CONCLUDE

1. Those students who failed to balance the equation, obtain the mole ratio, and compare the molar amounts of reactants likely predicted a doubling of the volume with each doubling of the mass of magnesium.
2. $Mg(s) + 2HCl(aq) \rightarrow MgCl_2(aq) + H_2(g)$
3. A mass of 0.60 g Mg is 0.025 mol Mg. Because Mg and HCl react in a 1:2 mol ratio, 0.10 mol HCl is in excess and Mg is limiting. According to the balanced equation, 0.025 mol Mg should produce 0.025 mol H_2. A mass of 1.2 g Mg is 0.050 mol Mg. According to the balanced equation, 0.050 mol Mg will react with 0.1 mol HCl to produce 0.05 mol H_2.
4. A mass of 2.4 g Mg is 0.10 mol Mg. Because there is only 0.1 mol HCl in the flask and, according to the equation, 0.20 mol HCl is needed to react with 0.10 mol Mg, HCl is limiting. Therefore, only 0.05 mol H_2 is produced.

FOR ENRICHMENT **Ask** What other clue could be used to determine if HCl was the limiting reagent? *(If HCl were the limiting reagent, remaining magnesium metal would be present after the reaction.)*

QuickLab

Purpose To illustrate the concept of a limiting reagent in a chemical reaction

Limiting Reagents

Materials

- graduated cylinder
- balance
- 3 250-mL Erlenmeyer flasks
- 3 rubber balloons
- 4.2 g magnesium ribbon
- 300 mL 1.0*M* hydrochloric acid

Procedure

1. Add 100 mL of the hydrochloric acid solution to each flask.
2. Weigh out 0.6 g, 1.2 g, and 2.4 g of magnesium ribbon, and place each sample into its own balloon.
3. Stretch the end of each balloon over the mouth of each flask. Do not allow the magnesium ribbon in the balloon to fall into the flask.
4. Magnesium reacts with hydrochloric acid to form hydrogen gas. When you mix the magnesium with the hydrochloric acid in the next step, you will generate a certain volume of hydrogen gas. How do you think the volume of hydrogen produced in each flask will compare?
5. Lift up on each balloon and shake the magnesium into each flask. Observe the volume of gas produced until the reaction in each flask is completed. Record your observations.

Analyze and Conclude

1. **Analyze Data** How did the volumes of hydrogen gas produced, as measured by the size of the balloons, compare? Did the results agree with your prediction?
2. **Apply Concepts** Write a balanced equation for the reaction you observed.
3. **Calculate** The 100 mL of hydrochloric acid contained 0.10 mol HCl. Show by calculation why the balloon with 1.2 g Mg inflated to about twice the size of the balloon with 0.60 g Mg.
4. **Calculate** Show by calculation why the balloons with 1.2 g and 2.4 g Mg inflated to approximately the same volume. What was the limiting reagent when 2.4 g Mg was added to the acid?

Percent Yield

What does the percent yield of a reaction measure?

When a teacher gives an exam to the class, every student could get a grade of 100 percent. However, this outcome generally does not occur. Instead, the performance of the class is usually spread over a range of grades. Your exam grade, expressed as a percentage, is a ratio of two items. The first item is the number of questions you answered correctly. The second is the total number of questions. The grade compares how well you performed with how well you could have performed if you had answered all the questions correctly. Chemists perform similar calculations in the laboratory when the product from a chemical reaction is less than expected, based on the balanced chemical equation.

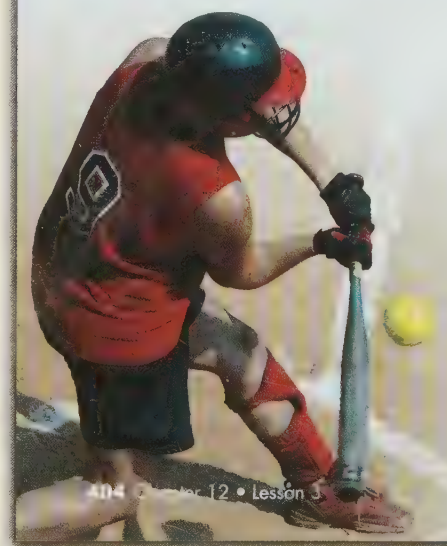


Figure 12.8 Batting Average
A batting average is actually a percent yield. A batting average is calculated by dividing the number of hits a batter has had (actual yield) by the number of at-bats (theoretical yield).

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups to complete the lab. Make sure each group has ELLs of varied language proficiency so that the more proficient students can help the less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Allow students to use drawings, single words, or short phrases. Demonstrate Steps 1–3 while reading each step out loud.

INTERMEDIATE:

LOW Write simplified procedures on the board or overhead projector.

HIGH Have students draft sentences to answer the questions that require writing.

ADVANCED: LOW/HIGH Have students assist classmates with lower language proficiency to set up and balance equations and answer questions.

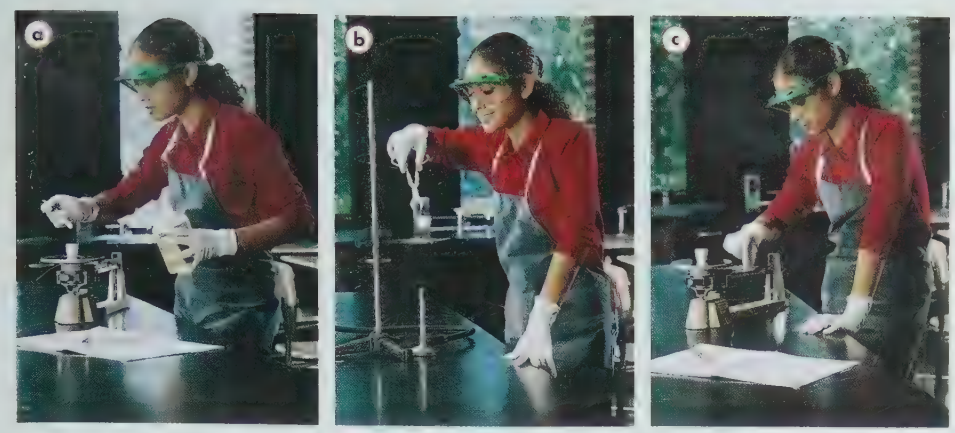

Figure 12.9 Determining Percent Yield
Sodium hydrogen carbonate ($NaHCO_3$) will decompose when heated. **a.** The mass of $NaHCO_3$, the reactant, is measured. **b.** The reactant is heated. **c.** The mass of one of the products, sodium carbonate (Na_2CO_3), the actual yield, is measured. The percent yield is calculated once the actual yield is determined.
Predict *What are the other products of this reaction?*

When a balanced chemical equation is used to calculate the amount of product that will form during a reaction, the calculated value represents the theoretical yield. The **theoretical yield** is the maximum amount of product that could be formed from given amounts of reactants. In contrast, the amount of product that actually forms when the reaction is carried out in the laboratory is called the **actual yield**. The **percent yield** is the ratio of the actual yield to the theoretical yield expressed as a percent.

$$\text{Percent yield} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100\%$$

Because the actual yield of a chemical reaction is often less than the theoretical yield, the percent yield is often less than 100 percent. **The percent yield is a measure of the efficiency of a reaction carried out in the laboratory.** This yield is similar to an exam score measuring your efficiency of learning or a batting average measuring your efficiency of hitting a baseball, as in Figure 12.8.

Stoichiometry and conservation of mass dictate that yields of greater than 100 percent are not possible. However, errors and lack of knowledge in a process can cause a reaction to apear to have a yield that is more than 100 percent. For example, if air or water leaks into a system, then more product may be formed than expected.

Many factors can cause percent yields to be less than 100 percent. Reactions do not always go to completion; when a reaction is incomplete, less than the calculated amount of product is formed. Impure reactants and competing side reactions may cause unwanted products to form. Actual yield can also be lower than the theoretical yield due to a loss of product during filtration or in transferring between containers. Moreover, if reactants or products have not been carefully measured, a percent yield of 100 percent is unlikely.

An actual yield is an experimental value. Figure 12.9 shows a typical laboratory procedure for determining the actual yield of a product of a decomposition reaction. For reactions in which percent yields have been determined, you can calculate and, therefore, predict an actual yield if the reaction conditions remain the same.

Percent Yield

APPLY CONCEPTS For industrial chemists or chemical engineers, the goal is to find cost-effective methods for converting reactants into products. Industrial chemists and chemical engineers want to achieve the maximum product yield at the lowest cost. One way to control costs is to minimize the amount of excess reagent by calculating stoichiometric quantities of the reactants.

Class Activity

PURPOSE Students assess actual yield of a reaction, based on temperature changes.

MATERIALS 3 foam cups, a thermometer, 100 mL of 1.0*M* HCl, and approximately 200 mL of 1.0*M* NaOH

SAFETY Students should wear safety glasses and aprons. HCl and NaOH are corrosive. Caution students to avoid skin contact with these chemicals. Neutralized solutions can be flushed down the drain with excess water.

PROCEDURE Write the balanced chemical equation on the board for students to use as a reference: $HCl(aq) + NaOH(aq) \rightarrow H_2O(l) + NaCl(aq) + \text{heat}$. Have students interpret the balanced equation as 1 mole of HCl reacts with 1 mole of NaOH to form 1 mole of NaCl and 1 mole of water. Have students transfer 30 mL of the HCl to a foam cup and measure the temperature. Next, have them add 10 mL of NaOH and gently stir the contents with the thermometer. Students should record the highest temperature reached as the reaction proceeds. Using a new cup each time, they should repeat the measurement with 30 mL of HCl and 30 mL of NaOH, and with 30 mL of HCl and 60 mL of NaOH.

EXPECTED OUTCOMES The second trial, in which reactants are present in a 1:1 mole ratio, produces the greatest temperature change. A slightly lower temperature change for the third trial can be accounted for by the greater mass of reagents.
Ask Which trial had the highest yield? *(the one that produced the greatest temperature change)*

Foundations for Reading

BUILD VOCABULARY Have students use the LINCS strategy for the terms *theoretical yield, actual yield,* and *percent yield.* Students should **L**ist the parts of a term they know; **I**magine a picture of the term; **N**ote a "sound-alike word" for the term; **C**onnect the terms; and **S**elf-test the terms.

Professional Development Note — Comparative Torch Temperatures

- Acetylene welding torches produce flame temperatures of 3300–3400°C.
- Propane torches reach flame temperatures of about 1400°C.
- The flame of a match has a temperature range of 600–800°C.

Explain

Percent Yield

CRITICAL THINKING Explain that some chemical processes are extremely costly, and low yields can have adverse effects on a company's profits. Have students research a pharmaceutical manufacturing company and learn about one of its processes. **Ask** What are some of the reasons for the expensive cost of the process? *(Sample answers: raw materials, materials of construction, high government standards of cleanliness)* **Ask** Why might this company *not* want to find cheaper raw materials for its product? *(Sample answer: It could affect the quality and effectiveness of the pharmaceutical product.)*

APPLY CONCEPTS Point out to students that solving stoichiometric problems requires a synthesis, or putting together, of chemical concepts, terms, and factual information. Write several problems on the board and have groups of students solve different problems, identifying the concepts, terms, and information necessary to do the problem.

MAKE A CONNECTION Relate percent yield to the mathematical concept of probability. Remind students that the experimental probability of an event is determined by the following:

$$\text{Probability} = \frac{\text{number of favorable outcomes}}{\text{total number of possible outcomes}}$$

Show students how the percent yield of a reaction is similar to probability; both concepts divide the actual result by the total possible.

$$\text{Percent Yield} = \frac{\text{actual amount of outcome}}{\text{total possible amount of outcome}}$$

Sample Problem 12.10

Calculating the Theoretical Yield of a Reaction

Calcium carbonate, which is found in seashells, is decomposed by heating. The balanced equation for this reaction is

$$CaCO_3(s) \xrightarrow{\Delta} CaO(s) + CO_2(g)$$

What is the theoretical yield of CaO if 24.8 g $CaCO_3$ is heated?

KNOWNS

mass of calcium carbonate = 24.8 g $CaCO_3$

1 mol $CaCO_3$ = 1 mol CaO

UNKNOWN

theoretical yield = ? g CaO

1 Analyze **List the knowns and the unknown.** Calculate the theoretical yield using the mass of the reactant:
g $CaCO_3$ ⟶ mol $CaCO_3$ ⟶ mol CaO ⟶ g CaO

2 Calculate **Solve for the unknown.**

Start with the mass of the reactant and convert to moles of the reactant.

$$24.8\ \text{g}\ CaCO_3 \times \frac{1\ \text{mol}\ CaCO_3}{100.1\ \text{g}\ CaCO_3}$$

Next, convert to moles of the product using the mole ratio.

$$24.8\ \text{g}\ CaCO_3 \times \frac{1\ \text{mol}\ CaCO_3}{100.1\ \text{g}\ CaCO_3} \times \frac{1\ \text{mol CaO}}{1\ \text{mol}\ CaCO_3}$$

Finish by converting from moles to mass of the product.

$$24.8\ \text{g}\ CaCO_3 \times \frac{1\ \text{mol}\ CaCO_3}{100.1\ \text{g}\ CaCO_3} \times \frac{1\ \text{mol CaO}}{1\ \text{mol}\ CaCO_3} \times \frac{56.1\ \text{g CaO}}{1\ \text{mol CaO}}$$

$$= 13.9\ \text{g CaO}$$

3 Evaluate **Does the result make sense?** The mole ratio of CaO to $CaCO_3$ is 1:1. The ratio of their masses in the reaction should be the same as the ratio of their molar masses, which is slightly greater than 1:2. The result of the calculations shows that the mass of CaO is slightly greater than half the mass of $CaCO_3$.

30. When 84.8 g of iron(III) oxide reacts with an excess of carbon monoxide, iron is produced.

$$Fe_2O_3(s) + 3CO(g) \longrightarrow 2Fe(s) + 3CO_2(g)$$

What is the theoretical yield of iron?

If there is an excess of a reactant, then there is more than enough of that reactant and it will not limit the yield of the reaction.

31. When 5.00 g of copper reacts with excess silver nitrate, silver metal and copper(II) nitrate are produced. What is the theoretical yield of silver in this reaction?

Foundations for Math

PERCENTS Caution students that the percent yield of a chemical reaction will not be greater than 100%. Point out that if the value they calculate is greater than 100%, they likely switched the placement of the numerator and denominator.

For struggling students, restate the percent yield formula out loud as "The percent yield is equal to the amount the reaction actually produced divided by the total possible amount the reaction could have produced." Encourage students to write the formula in their own words.

(Sample answer: Percent Yield = $\frac{\text{what I got}}{\text{what was possible to get}}$)

Success Stats

You may not use the term "percent yield" outside of chemistry class, but there are many examples of percent yield in our lives. In chemical reactions, percent yield refers to the amount of product formed in a reaction compared to how much product was possible. In school, percent yield could refer to the graduation rate or a score on a test. In sports, percent yield could refer to the percent of shots that make it into a goal. The actual performance of a product compared to its advertised performance is also an example of percent yield.

Whether it's in the chemistry lab or anywhere else, percent yield is a way to measure how successfully something or someone has performed. The next time you calculate the percent yield of a chemical reaction, think about how this skill could be used in other situations outside of chemistry class.

85 PERCENT PERFORMANCE

Actual Yield: 156 minutes during which a drink stayed hot in thermos

Theoretical Yield: 180 minutes, as advertised by the thermos manufacturer

38 PERCENT SHOT CONVERSION RATE

Actual Yield: 8 goals scored

Theoretical Yield: 21 shots on goal

95 PERCENT GRADUATION RATE

Actual Yield: 305 students graduating

Theoretical Yield: 321 students in the senior class

Take It Further

1. Calculate Sara's car is advertised to get 43 miles per gallon. Sara calculated her gas mileage over the last month and found that it was 39 miles per gallon. What is the percent yield of Sara's gas mileage.

2. Identify The percent yield of a reaction may be different each time the reaction occurs. Similarly, the performance of an athlete may vary. What are some factors that might affect percent yield?

Differentiated Instruction

L1 STRUGGLING STUDENTS If students are having difficulty with Question 1, have them review **Sample Problem 12.11** in Lesson 12.3. If students are having difficulty with Question 2, have them review the Percent Yield section of Lesson 12.3.

ELL ENGLISH LANGUAGE LEARNERS Have students work in groups of mixed proficiencies to answer questions.

L3 ADVANCED STUDENTS Have students research and compare analytical balances of different sensitivities, and have students show mathematically how using a balance of too little or too great a sensitivity can affect theoretical and percent yields.

CHEMISTRY & YOU Draw students' attention to the photo of the insulated container and to its caption. Point out that products like this container are manufactured to meet a certain set of standards specified by the manufacturer. However, quality control inspectors are allowed to pass products that perform within a certain narrow range on either side of the given standards. In the case of the insulated container in the photo, the advertised number of hours that the container will keep a drink hot is most likely based on the properties of the container's materials and the properties of a standard beverage.

Pose the following question to students: *What factors determine how long the container keeps its contents hot? Assume that during manufacturing, the properties of the materials used to make all the containers are consistent. Also assume that all the containers meet the manufacturer's specifications.*

You may need to assist students in the following ways:

- The contents are most likely solutions (beverages) or mixtures of solids and liquids (soups, stews, etc.).
- The wide variety of environmental conditions to which the container will be exposed during normal use cannot be accurately duplicated in a quality control laboratory.
- The container's owner may not adhere to the manufacturer's care instructions for the container.

Answers

30. 59.3 g Fe

31. 17.0 g Ag

TAKE IT FURTHER

1. 90.7%
2. Answers may vary. Environmental conditions of the reaction and the quality of the reactants may affect the percent yield.

CHEMISTRY & YOU

START A CONVERSATION Ask students if they have ever observed a campfire or fireplace the next day after the fire has gone out. In most cases, there will be some unburned or partially burned pieces of wood left. Similarly, during a chemical reaction, some portions of the reactants may remain unreacted. Percent yield calculations will determine what percentage of each reactant was actually consumed in chemical reactions.

Evaluate

Informal Assessment

Following the safety precautions listed in the Quick Lab on page 374, place a small piece of zinc in a large beaker of dilute hydrochloric acid. Explain the reaction to the students.

$$Zn(s) + 2HCl(aq) \rightarrow ZnCl_2(aq) + H_2(g)$$

Ask Which of the two reactants is the limiting reagent? *(If the zinc completely disappears after some time, students may conclude that the zinc is used up first, and is, therefore, the limiting reagent.)*
Ask How can you test your hypothesis? *(Sample answers: Measure the volume of H_2 produced for various amounts of zinc added to a fixed volume of HCl; determine the stoichiometric quantity of zinc, the amount that reacts to give the greatest volume of H_2.)*

Sample Problem 12.11

Calculating the Percent Yield of a Reaction

What is the percent yield if 13.1 g CaO is actually produced when 24.8 g $CaCO_3$ is heated?

$$CaCO_3(s) \xrightarrow{\Delta} CaO(s) + CO_2(g)$$

1 Analyze **List the knowns and the unknown.** Use the equation for percent yield. The theoretical yield for this problem was calculated in Sample Problem 12.10.

KNOWNS
actual yield = 13.1 g CaO
theoretical yield = 13.9 g CaO (from Sample Problem 12.10)

UNKNOWN
percent yield = ? %

2 Calculate **Solve for the unknown.**

$$\text{percent yield} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100\%$$

Substitute the values for actual yield and theoretical yield into the equation for percent yield.

$$\text{percent yield} = \frac{13.1\ \text{g CaO}}{13.9\ \text{g CaO}} \times 100\% = 94.2\%$$

3 Evaluate **Does the result make sense?** In this example, the actual yield is slightly less than the theoretical yield. Therefore, the percent yield should be slightly less than 100 percent.

32. If 50.0 g of silicon dioxide is heated with an excess of carbon, 27.9 g of silicon carbide is produced.

$$SiO_2(s) + 3C(s) \xrightarrow{\Delta} SiC(s) + 2CO(g)$$

What is the percent yield of this reaction?

33. If 15.0 g of nitrogen reacts with 15.0 g of hydrogen, 10.5 g of ammonia is produced. What is the percent yield of this reaction?

Calculate the theoretical yield first. Then you can calculate the percent yield.

12.3 LessonCheck

34. **Relate Cause and Effect** In a chemical reaction, how does an insufficient quantity of a reactant affect the amount of product formed?

35. **Explain** How can you gauge the efficiency of a reaction carried out in the laboratory?

36. **Define** What is a limiting reagent? An excess reagent?

37. **Calculate** How many grams of SO_3 are produced when 20.0 g FeS_2 reacts with 16.0 g O_2 according to this balanced equation?

$$4FeS_2(s) + 15O_2(g) \longrightarrow 2Fe_2O_3(s) + 8SO_3(g)$$

38. **Calculate** What is the percent yield if 4.65 g of copper is produced when 1.87 g of aluminum reacts with an excess of copper(II) sulfate?

$$2Al(s) + 3CuSO_4(aq) \longrightarrow Al_2(SO_4)_3(aq) + 3Cu(s)$$

Lesson Check Answers

34. In a chemical reaction, an insufficient quantity of any of the reactants will limit the amount of product that forms.

35. The efficiency of a reaction carried out in a laboratory can be measured by calculating the percent yield.

36. A limiting reagent is a reagent that determines how much product can be formed in a reaction. An excess reagent is a reactant that is not completely used up in a reaction.

37. 26.7 g SO_3

38. 70.5%

12 Study Guide

BIG IDEAS

- THE MOLE AND QUANTIFYING MATTER
- REACTIONS

Balanced chemical equations are the basis for stoichiometric calculations. The coefficients of a balanced equation indicate the number of particles, moles, or volumes of gas in the reaction. Mole ratios from the balanced equation are used to calculate the amount of a reactant or product in a chemical reaction from a given amount of one of the reactants or products.

12.1 The Arithmetic of Equations

Chemists use balanced chemical equations as a basis to calculate how much reactant is needed or product is formed in a reaction.

A balanced chemical equation can be interpreted in terms of different quantities, including numbers of atoms, molecules, or moles; mass; and volume.

- stoichiometry (386)

12.2 Chemical Calculations

In chemical calculations, mole ratios are used to convert between a given number of moles of a reactant or product to moles of a different reactant or product.

In a typical stoichiometric problem, the given quantity is first converted to moles. Then, the mole ratio from the balanced equation is used to calculate the moles of the wanted substance. Finally, the moles are converted to any other unit of measurement related to the unit mole.

- mole ratio (390)

Key Equation

mole-mole relationship for $aG \rightarrow bW$:

$$x \text{ mol } G \times \frac{b \text{ mol } W}{a \text{ mol } G} = \frac{xb}{a} \text{ mol } W$$

12.3 Limiting Reagent and Percent Yield

In a chemical reaction, an insufficient quantity of any of the reactants will limit the amount of product that forms.

The percent yield is a measure of the efficiency of a reaction performed in the laboratory.

- limiting reagent (401)
- excess reagent (401)
- theoretical yield (405)
- actual yield (405)
- percent yield (405)

Key Equation

$$\text{percent yield} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100\%$$

UbD Performance Tasks

CHEMICAL MANUFACTURING Have students write a paragraph describing a hypothetical chemical product that they are manufacturing. Students should describe their product, explain why their process has excess or limiting reagents, and show how they determine the actual, theoretical, and percent yields of their product.

STOICHIOMETRIC SHOWDOWN Write a set of unbalanced chemical equations on the board. Have students balance each equation. Have students determine the number of representative particles and moles, the molar mass of each reactant and product, and the mass of each reactant and product. Then, have students identify all of the mole ratios in each equation.

What's Online

Review and Assessment Resources

WALK-THRU TUTORIALS Each of the Math Tune-Up problems on the following page has an animated step-by-step tutorial that explains the problem-solving strategy in detail.

PROBLEM SETS Have students practice more problems using the Chapter 12 Online Problem Set.

MATH SKILLS Have struggling students practice manipulating algebraic equations using the MathXL learning module.

VIRTUAL LAB Have students complete the virtual lab as an in-class or take-home assignment to help reinforce the mathematical relationships utilized in stoichiometric calculations. To have students investigate the calculation of the mass of sodium hydrogen carbonate in a sample of baking soda, assign the lab Analysis of Baking Soda.

Study Tip

PRIORITIZE Schedule your time realistically. Stick to your deadlines.

Math Tune-Up: Stoichiometry Problems

Problem

Iron metal (Fe) can be obtained from iron ore, Fe_2O_3.

$$Fe_2O_3(s) + 3CO(g) \longrightarrow 2Fe(s) + 3CO_2(g)$$

How much iron ore is needed to obtain 92.8 grams of iron metal?

Sodium hydroxide reacts with carbon dioxide according to the balanced equation below.

$$2NaOH(s) + CO_2(g) \longrightarrow Na_2CO_3(s) + H_2O(l)$$

What is the limiting reagent when 3.50 mol NaOH reacts with 2.00 mol CO_2?

1 Analyze

Knowns:
mass of iron = 92.8 g Fe
1 mol Fe_2O_3 / 2 mol Fe (from balanced equation)
1 mol Fe = 55.8 g Fe (molar mass)
1 mol Fe_2O_3 = 159.6 g Fe_2O_3 (molar mass)

Unknown:
Mass of iron ore = ? g Fe_2O_3

Knowns:
moles of NaOH = 3.50 mol NaOH
moles of CO_2 = 2.00 mol CO_2

Unknown:
limiting reagent = ?

2 Calculate

Perform the following steps:
g Fe ⟶ mol Fe ⟶ mol Fe_2O_3 ⟶ g Fe_2O_3

$$92.8\ \text{g Fe} \times \frac{1\ \text{mol Fe}}{55.8\ \text{g Fe}} \times \frac{1\ \text{mol } Fe_2O_3}{2\ \text{mol Fe}} \times \frac{159.6\ \text{g } Fe_2O_3}{1\ \text{mol } Fe_2O_3}$$

$$= 133.0\ \text{g } Fe_2O_3$$

Hint: Review Sample Problem 12.4 if you have trouble with calculating the mass of a reactant.

Determine how many moles of CO_2 are needed to react with 3.50 mol NaOH.

$$3.50\ \text{mol NaOH} \times \frac{1\ \text{mol } CO_2}{2\ \text{mol NaOH}}$$

$$= 1.75\ \text{mol } CO_2$$

Only 1.75 mol CO_2 are needed to react with 3.50 mol NaOH. Since there are 2.00 mol CO_2, there is excess CO_2. Therefore, NaOH is the limiting reagent.

3 Evaluate

Since the molar mass of the iron ore is more than twice the molar mass of iron metal, it makes sense that the mass of the iron ore would be greater than the mass of the iron metal produced.

To check your work, you could start with the given amount of moles of CO_2 and solve for how many moles of NaOH are needed.

Hint: Review Sample Problem 12.8 if you have trouble identifying the limiting reagent.

Focus on ELL

5 ASSESS UNDERSTANDING Place students in groups of three for an alternative assessment assignment. Provide each group of students with a grading rubric, and explain that they are to depict the *question* and *answer* to **one** key question from **each** lesson in Chapter 12. Suggest the following ideas to the appropriate groups:

BEGINNING

LOW Create cartoon-type drawings.

HIGH Draw pictures with simple labels or captions.

INTERMEDIATE

LOW Design and act out a role-playing scenario.

HIGH Use models or create a diagram and provide simple descriptions.

ADVANCED: LOW/HIGH Create a poster and give an oral presentation to the class.

12 Assessment

* Solutions appear in Appendix E

Lesson by Lesson

12.1 The Arithmetic of Equations

39. Interpret each chemical equation in terms of interacting particles.

a. $2KClO_3(s) \longrightarrow 2KCl(s) + 3O_2(g)$
b. $4NH_3(g) + 6NO(g) \longrightarrow 5N_2(g) + 6H_2O(g)$
c. $4K(s) + O_2(g) \longrightarrow 2K_2O(s)$

40. Interpret each equation in Problem 39 in terms of interacting numbers of moles of reactants and products.

41. Calculate and compare the mass of the reactants with the mass of the products for each equation in Problem 39. Show that each balanced equation obeys the law of conservation of mass.

42. Balance the following equation:

$$C_5H_{12}(g) + O_2(g) \longrightarrow CO_2(g) + H_2O(g)$$

Interpret the balanced equation in terms of relative number of moles, volumes of gas at STP, and masses of reactants and products.

12.2 Chemical Calculations

43. Explain the term *mole ratio* in your own words. When would you use this term?

44. What ratio is used to carry out each conversion?

a. mol CH_4 to g CH_4
b. L $CH_4(g)$ to mol $CH_4(g)$ (at STP)
c. molecules CH_4 to mol CH_4

***45.** Carbon disulfide is an important industrial solvent. It is prepared by the reaction of coke with sulfur dioxide.

$$5C(s) + 2SO_2(g) \longrightarrow CS_2(l) + 4CO(g)$$

a. How many moles of CS_2 form when 2.7 mol C reacts?
b. How many moles of carbon are needed to react with 5.44 mol SO_2?
c. How many moles of carbon monoxide form at the same time that 0.246 mol CS_2 forms?
d. How many mol SO_2 are required to make 118 mol CS_2?

***46.** Methanol (CH_3OH) is used in the production of many chemicals. Methanol is made by reacting carbon monoxide and hydrogen at high temperature and pressure.

$$CO(g) + 2H_2(g) \longrightarrow CH_3OH(g)$$

a. How many moles of each reactant are needed to produce 3.60×10^2 g CH_3OH?
b. Calculate the number of grams of each reactant needed to produce 4.00 mol CH_3OH.
c. How many grams of hydrogen are necessary to react with 2.85 mol CO?

47. The reaction of fluorine with ammonia produces dinitrogen tetrafluoride and hydrogen fluoride.

$$5F_2(g) + 2NH_3(g) \longrightarrow N_2F_4(g) + 6HF(g)$$

a. If you have 66.6 g NH_3, how many grams of F_2 are required for a complete reaction?
b. How many grams of NH_3 are required to produce 4.65 g HF?
c. How many grams of N_2F_4 can be produced from 225 g F_2?

48. What information about a chemical reaction is derived from the coefficients in a balanced equation?

49. Rust is produced when iron reacts with oxygen.

$$4Fe(s) + 3O_2(g) \longrightarrow 2Fe_2O_3(s)$$

How many grams of Fe_2O_3 are produced when 12.0 g of iron rusts?

***50.** Lithium nitride reacts with water to form ammonia and aqueous lithium hydroxide.

$$Li_3N(s) + 3H_2O(l) \longrightarrow NH_3(g) + 3LiOH(aq)$$

a. What mass of water is needed to react with 32.9 g Li_3N?
b. When the above reaction takes place, how many molecules of NH_3 are produced?
c. Calculate the number of grams of Li_3N that must be added to an excess of water to produce 15.0 L NH_3 (at STP).

Evaluate

Answers

LESSON 12.1

39. **a.** Two formula units $KClO_3$ decompose to form two formula units KCl and three molecules O_2.
b. Four molecules NH_3 react with six molecules NO to form five molecules N_2 and six molecules H_2O.
c. Four atoms K react with one molecule O_2 to form two formula units K_2O.

40. **a.** Two mol $KClO_3$ decompose to form two mol KCl and three mol O_2.
b. Four mol NH_3 react with six mol NO to form five mol N_2 and six mol H_2O.
c. Four mol K react with one mol O_2 to form two mol K_2O.

41. **a.** 245.2 g **b.** 248.0 g **c.** 188.4 g
All obey the law of conservation of mass.

42. 1 mol $C_5H_{12}(g)$ + 8 mol $O_2(g) \rightarrow$ 5 mol $CO_2(g)$ + 6 mol $H_2O(g)$; 22.4 L $C_5H_{12}(g)$ + 179 L $O_2(g) \rightarrow$ 112 L $CO_2(g)$ + 134 L $H_2O(g)$; 328 g reactants $\rightarrow$ 328 g products

LESSON 12.2

43. Acceptable answers include the idea of writing a ratio using the coefficients of two substances from a balanced equation as the number of moles of each substance reacting or being formed.

44. **a.** 16.0 g CH_4/1 mol CH_4
b. 1 mol CH_4/22.4 L CH_4
c. 1 mol CH_4/6.02×10^{23} molecules CH_4

45. **a.** 0.54 mol **b.** 13.6 mol **c.** 0.984 mol **d.** 236 mol

46. **a.** 11.3 mol CO, 22.5 mol H_2
b. 112 g CO, 16.0 g H_2
c. 11.4 g H_2

47. **a.** 372 g F_2
b. 1.32 g NH_3
c. 123 g N_2F_4

48. The coefficients indicate the relative numbers of moles (or particles) of reactants and products.

49 17.2 g

50. **a.** 51.2 g H_2O
b. 5.71×10^{23} molecules NH_3
c. 23.2 g Li_3N

ASSESSMENT

Evaluate

Answers

LESSON 12.3

51. The amount of the limiting reagent determines the maximum amount of product that can be formed. The excess reagent is only partially consumed in the reaction.

52. To identify the limiting reagent, express quantities of reactants as moles; compare to the mole ratios from the balanced equation.

53. **a.** Al
b. 3.0 mol $AlCl_3$
c. 0.8 mol Cl_2

54. 91.1%

55. 5.25 mol NaOH required; NaOH is the limiting reagent

UNDERSTAND CONCEPTS

56. **a.** 2.36 g H_3PO_4
b. 1.89 g CO_2

57. **a.** 5.70×10^{21} atoms Zn
b. 95.2 g Zn

58. 87.0%

59. **a.** Initially, the amount of NaCl formed increases as the amount of Na used increases. For this part of the curve, sodium is the limiting reagent. Beyond a mass of about 2.5 g of Na, the amount of product formed remains constant because chlorine is now the limiting reagent.
b. Chlorine becomes the limiting reagent when the mass of sodium exceeds 2.5 g. This corresponds to a mass of about 3.9 g chlorine.

60 **a.** 7.0×10 L N_2
b. The excess remaining reagent is 0.2 kg O_2.

12.3 Limiting Reagent and Percent Yield

51. What is the significance of the limiting reagent in a reaction? What happens to the amount of any reagent that is present in an excess?

52. How would you identify a limiting reagent in a chemical reaction?

***53.** In a reaction chamber, 3.0 mol of aluminum is mixed with 5.3 mol Cl_2 and reacts. The following balanced chemical equation describes the reaction:

$$2Al(s) + 3Cl_2(g) \longrightarrow 2AlCl_3(s)$$

a. Identify the limiting reagent for the reaction.
b. Calculate the number of moles of product formed.
c. Calculate the number of moles of excess reagent remaining after the reaction.

***54.** Heating an ore of antimony (Sb_2S_3) in the presence of iron gives the element antimony and iron(II) sulfide.

$$Sb_2S_3(s) + 3Fe(s) \longrightarrow 2Sb(s) + 3FeS(s)$$

When 15.0 g Sb_2S_3 reacts with an excess of Fe, 9.84 g Sb is produced. What is the percent yield of this reaction?

55. Phosphoric acid reacts with sodium hydroxide according to the equation:

$$H_3PO_4(aq) + 3NaOH(aq) \longrightarrow Na_3PO_4(aq) + 3H_2O(l)$$

If 1.75 mol H_3PO_4 is made to react with 5.00 mol NaOH, identify the limiting reagent.

Understand Concepts

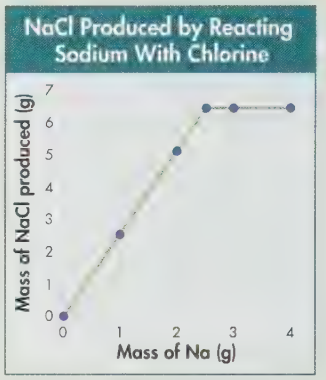
56. Calcium carbonate reacts with phosphoric acid to produce calcium phosphate, carbon dioxide, and water.

$$3CaCO_3(s) + 2H_3PO_4(aq) \longrightarrow Ca_3(PO_4)_2(aq) + 3CO_2(g) + 3H_2O(l)$$

a. How many grams of phosphoric acid react with excess calcium carbonate to produce 3.74 g $Ca_3(PO_4)_2$?
b. Calculate the number of grams of CO_2 formed when 0.773 g H_2O is produced.

***57.** Nitric acid and zinc react to form zinc nitrate, ammonium nitrate, and water.

$$4Zn(s) + 10HNO_3(aq) \longrightarrow 4Zn(NO_3)_2(aq) + NH_4NO_3(aq) + 3H_2O(l)$$



a. How many atoms of zinc react with 1.49 g HNO_3?
b. Calculate the number of grams of zinc that must react with an excess of HNO_3 to form 29.1 g NH_4NO_3.

58. If 75.0 g of silderite ore ($FeCO_3$) is heated with an excess of oxygen, 45.0 g of ferric oxide (Fe_2O_3) is produced.

$$4FeCO_3(s) + O_2(g) \longrightarrow 2Fe_2O_3(s) + 4CO_2(g)$$

What is the percent yield of this reaction?

59. In an experiment, varying masses of sodium metal are reacted with a fixed initial mass of chlorine gas. The following graph shows the amounts of sodium used and the amounts of sodium chloride formed.

a. Explain the general shape of the graph.
b. Estimate the amount of chlorine gas used in this experiment at the point where the curve becomes horizontal.

***60.** Hydrazine (N_2H_4) is used as rocket fuel. It reacts with oxygen to form nitrogen and water.

$$N_2H_4(l) + O_2(g) \longrightarrow N_2(g) + 2H_2O(g)$$

a. How many liters of N_2 (at STP) form when 1.0 kg N_2H_4 reacts with 1.2 kg O_2?
b. How many grams of the excess reagent remain after the reaction?

61. When 50.0 g of silicon dioxide is heated with an excess of carbon, 32.2 g of silicon carbide is produced.

$$SiO_2(s) + 3C(s) \longrightarrow SiC(s) + 2CO(g)$$

a. What is the percent yield of this reaction?
b. How many grams of CO gas are made?

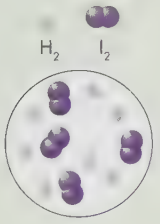
62. If the reaction below proceeds with a 96.8% yield, how many kilograms of $CaSO_4$ are formed when 5.24 kg SO_2 reacts with an excess of $CaCO_3$ and O_2?

$$2CaCO_3(s) + 2SO_2(g) + O_2(g) \longrightarrow 2CaSO_4(s) + 2CO_2(g)$$

63. Ammonium nitrate will decompose explosively at high temperatures to form nitrogen, oxygen, and water vapor.

$$2NH_4NO_3(s) \longrightarrow 2N_2(g) + 4H_2O(g) + O_2(g)$$

What is the total number of liters of gas formed when 228 g NH_4NO_3 is decomposed? (Assume STP.)



***64.** Hydrogen gas can be made by reacting methane (CH_4) with high-temperature steam:

$$CH_4(g) + H_2O(g) \longrightarrow CO(g) + 3H_2(g)$$

How many hydrogen molecules are produced when 158 g of methane reacts with steam?

65. Suppose hydrogen gas and iodine vapor react to give gaseous hydrogen iodide.

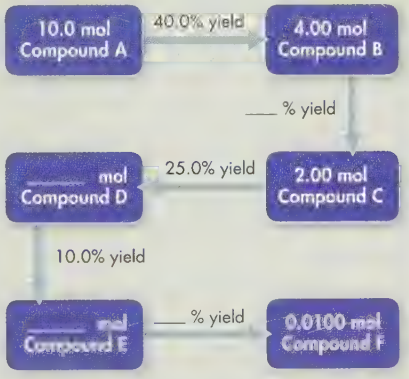
a. Write the balanced equation for the reaction.
b. In the atomic window below, which reactant is the limiting reagent?
c. How many molecules of the reagent in excess remain at the completion of the reaction?
d. How many molecules of the limiting reagent need to be added to the atomic window so that all the reactants will react to form products?

66. The following reaction occurs when an automobile battery is charged.

$$PbSO_4(s) + H_2O(l) \longrightarrow PbO_2(s) + Pb(s) + H_2SO_4(aq)$$

a. Balance the equation.
b. How many grams of sulfuric acid are produced when 68.1 g of lead(II) sulfate react?

***67.** Liquid sulfur difluoride reacts with fluorine gas to form gaseous sulfur hexafluoride.



a. Write the balanced equation for the reaction.
b. How many fluorine molecules are required to react with 5.00 mg of sulfur difluoride?
c. What volume of fluorine gas at STP is required to react completely with 6.66 g of sulfur difluoride?

68. Ammonia (NH_3) reacts with oxygen (O_2) to produce nitrogen monoxide (NO) and water.

$$4NH_3(g) + 5O_2(g) \longrightarrow 4NO(g) + 6H_2O(l)$$

How many liters of NO are produced when 1.40 L of oxygen reacts with ammonia?

***69.** The manufacture of compound F requires five separate chemical reactions. The initial reactant, compound A, is converted to compound B, compound B is converted to compound C, and so on. The diagram below summarizes the steps in the manufacture of compound F, including the percent yield for each step. Provide the missing quantities or missing percent yields. Assume that the reactant and product in each step react in a one-to-one mole ratio.

ASSESSMENT

61. **a.** 96.4%
b. 45.0 kg
62. 10.7 kg $CaSO_4$
63. 224 L gas
64. 1.78×10^{25} molecules H_2
65. **a.** $H_2(g) + I_2(g)$ 2HI(g)
b. I_2
c. 2 molecules H_2
d. 2 molecules of I_2
66. **a.** $2PbSO_4(s) + 2H_2O(l)$ $PbO_2(s) + Pb(s) + 2H_2SO_4(aq)$
b. 22.1 g H_2SO_4
67. **a.** $SF_2(l) + 2F_2(g) + SF_6(g)$
b. 8.59×10^{19} molecules
c. 4.26 L F_2
68. 1.12 L NO
67. **a.** Initially, the amount of NaCl formed increases as the amount of Na used increases. For this part of the curve, sodium is the limiting reagent. Beyond a mass of about 2.5 g of Na, the amount of product formed remains constant because chlorine is now the limiting reagent.
b. Chlorine becomes the limiting reagent when the mass of sodium exceeds 2.5 g. This corresponds to a mass of about 3.9 g chlorine.
69. 50.0% yield; 0.500 mol; 0.0500 mol; 20.0% yield

ASSESSMENT

THINK CRITICALLY

70. The percent yield is 115%; such a yield could be attributed to experimenter error, to unreacted starting material, or to outside materials contaminating the product.

71. Yes, a net ionic equation is balanced and thus obeys the law of conservation of mass.

72. **a.** $P_4O_{10} + 10C \rightarrow P_4 + 10CO$
b. SiO_2
c. 7.9×10^4 g P_4
d. 7.7×10^4 g C

73. **a.** $H_2SO_4 + Ca(OH)_2 \rightarrow CaSO_4 + 2H_2O$
b. 2.26 g H_2SO_4

74. 1.1×10^6 L air

75. 13 days

76. **a.** 29 frames
b. 58 wheels
c. 174 pedals
d. 87 seats

ENRICHMENT

77. 1.86 g/L

78. 87.4% $CaCO_3$

79. KOH is the limiting reagent.

Think Critically

70. Evaluate Given a certain quantity of reactant, you calculate that a particular reaction should produce 55 g of a product. When you perform the reaction, you find that you have produced 63 g of product. What is your percent yield? What could have caused a percent yield greater than 100 percent?

71. Explain Would the law of conservation of mass hold in a net ionic equation? Explain.

***72. Calculate** The element phosphorus is manufactured from a mixture of phosphate rock ($Ca_3(PO_4)_2$), sand (SiO_2), and coke (C) in an electric furnace. The chemistry is complex but is summarized by these two equations.

$$Ca_3(PO_4)_2 + SiO_2 \longrightarrow P_4O_{10} + CaSiO_3$$

$$P_4O_{10} + C \longrightarrow P_4 + CO$$

An excess of coke is reacted with 5.5×10^5 g of calcium phosphate and 2.3×10^5 g of sand.

a. Balance each of the equations.
b. What is the limiting reagent?
c. How many grams of phosphorus are produced?
d. How many grams of carbon are consumed?

73. Calculate Sulfuric acid reacts with calcium hydroxide to form calcium sulfate and water.

a. Write the balanced equation for the reaction.
b. Find the mass of unreacted starting material when 75.0 g sulfuric acid reacts with 55.0 g calcium hydroxide.

74. Apply Concepts A car gets 9.2 kilometers to a liter of gasoline. Assuming that gasoline is 100% octane (C_8H_{18}), which has a density of 0.69 g/cm^3, how many liters of air (21% oxygen by volume at STP) will be required to burn the gasoline for a 1250-km trip? Assume complete combustion.

***75. Calculate** Ethyl alcohol (C_2H_5OH) can be produced by the fermentation of glucose ($C_6H_{12}O_6$). If it takes 5.0 h to produce 8.0 kg of alcohol, how many days will it take to consume 1.0×10^3 kg of glucose? (An enzyme is used as a catalyst.)

$$C_6H_{12}O_6 \xrightarrow{\text{enzyme}} 2C_2H_5OH + 2CO_2$$

76. Calculate A bicycle built for three has a frame, two wheels, six pedals, and three seats. The balanced equation for this bicycle is

$$F + 2W + 6P + 3S \longrightarrow FW_2P_6S_3$$

How many of each part are needed to make 29 bicycles built for three?

a. frames
b. wheels
c. pedals
d. seats

Enrichment

77. Calculate A 1004.0-g sample of $CaCO_3$ that is 95.0% pure gives 225 L CO_2 at STP when reacted with an excess of hydrochloric acid.

$$CaCO_3 + 2HCl \longrightarrow CaCl_2 + CO_2 + H_2O$$

What is the density (in g/L) of the CO_2?

***78. Calculate** The white limestone cliffs of Dover, England, contain a large percentage of calcium carbonate ($CaCO_3$). A sample of limestone with a mass of 84.4 g reacts with an excess of hydrochloric acid to form calcium chloride.

$$CaCO_3 + 2HCl \longrightarrow CaCl_2 + H_2O + CO_2$$

The mass of calcium chloride formed is 81.8 g. What is the percentage of calcium carbonate in the limestone?

79. Calculate For the reaction below there are 100.0 g of each reactant available. Which reactant is the limiting reagent?

$$2MnO_2 + 4KOH + O_2 + Cl_2 \longrightarrow 2KMnO_4 + 2KCl + 2H_2O$$

80. Calculate The equation for one of the reactions in the process of reducing iron ore to the metal is

$$Fe_2O_3(s) + 3\,CO(g) \longrightarrow 2\,Fe(s) + 3\,CO_2(g)$$

a. What is the maximum mass of iron, in grams, that can be obtained from 454 g (1.00 lb) of iron(III) oxide?

b. What mass of CO is required to reduce the iron(III) oxide to iron metal?

81. Calculate Esters are a class of compounds that impart a characteristic odor to some fruits. The ester pentyl acetate, composed of carbon, hydrogen, and oxygen, has the odor of bananas. When 7.44 g of this compound undergoes complete combustion, 17.6 g CO_2 and 7.21 g H_2O are produced.

a. What is the empirical formula of pentyl acetate? (*Hint:* All the carbon ends up in the CO_2; all the hydrogen ends up in the H_2O.)

b. The molar mass of pentyl acetate is 130.0 g. What is the molecular formula of this compound?

c. Write the equation for the complete combustion of pentyl acetate.

d. Check your work by using your equation from part c to calculate the grams of CO_2 and H_2O produced by the complete combustion of 7.44 g of pentyl acetate.

***82. Calculate** Nitric acid, HNO_3, is produced in a complex three-step process summarized by these unbalanced equations.

Step 1: $NH_3 + O_2 \longrightarrow NO + H_2O$

Step 2: $NO + O_2 \longrightarrow NO_2$

Step 3: $NO_2 + H_2O \longrightarrow HNO_3 + NO$

Notice that the nitric oxide, NO, produced in Step 3 is recycled into Step 2.

a. Balance each of the equations.

b. Assuming all the nitrogen from the ammonia will eventually be incorporated into the nitric acid, calculate the mass of nitric acid obtained from 88.0 g NH_3.

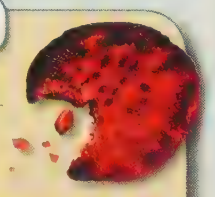
c. The concentrated nitric acid used in the lab is a 70.0% by mass solution of HNO_3 in water. Using your answer from part b, calculate the mass of ammonia needed to prepare 1.00 kg of concentrated nitric acid.

83. Calculate SO_3 can be produced in the following two-step process:

$$FeS_2 + O_2 \longrightarrow Fe_2O_3 + SO_2$$

$$SO_2 + O_2 \longrightarrow SO_3$$

Assuming that all the FeS_2 reacts, how many grams of SO_3 are produced when 20.0 g of the FeS_2 reacts with 16.0 g of O_2?



Write About Science

84. Explain Explain this statement: "Mass and atoms are conserved in every chemical reaction, but moles are not necessarily conserved."

85. Explain Review the "mole road map" at the end of Lesson 10.2. Explain how this road map ties into the summary of steps for stoichiometric problems shown in Figure 12.5.

CHEMYSTERY

Cookie Crumbles

Jack tried to make cookies that were extra sweet by adding more sugar than was in the recipe. What Jack didn't realize is that a recipe is like a balanced chemical equation. In order to get the desired product in the reaction of cooking, the reactants, or ingredients, must be combined in specific ratios. Jack changed the amount of sugar, but he didn't change any of the other ingredients. Therefore, he changed the ratios of the ingredients. Balanced chemical equations are important in cooking and in many other fields.

86. Infer If Jack's recipe calls for 2.5 cups of flower and 2 eggs, and Jack wants to scale up the recipe by 50 percent, then how much flower and eggs will he need?

87. Connect to the **BIG**IDEA How does Jack's baking experience illustrate the concept of a limiting reagent?

80. **a.** 347 g Fe
b. 239 g CO

81. **a.** $C_7H_{14}O_2$
b. $C_7H_{14}O_2$
c. $2\,C_7H_{14}O_2 + 19O_2 \rightarrow 14CO_2 + 14H_2O$
d. 17.6 g CO_2 and 7.21 g H_2O are produced

82. **a.** $4NH_3 + 5O_2 \rightarrow 4NO + 6H_2O$
$2NO + O_2 \rightarrow 2NO_2$
$3NO_2 + H_2O \rightarrow 2HNO_3 + NO$
b. 326 g HNO_3
c. 189 g NH_3

83. 6.51 g SO_3

WRITE ABOUT SCIENCE

84. Moles of reactants and products are conserved for some reactions, but this is generally not the case.

85. Figure 10.12, the "mole road map," describes how the mass, volume, and number of representative particles of a substance can be converted into moles (and vice versa). These relationships apply to six of the calculations shown in Figure 12.8; the seventh is a mole-mole conversion, based on a mole ratio.

ASSESSMENT

CHEMYSTERY **START A CONVERSATION** Ask students if anyone watches cooking shows on television. Ascertain if they have seen a chef on one of these shows cook a dish without measuring ingredients. *(Sample answers: chefs often use approximate measurements, "eyeball" ingredients, or add pinches of seasonings to meats, vegetables, and other savory dishes.)* **Ask** Do these same chefs use any approximate measurements when baking? If so, which ingredients do the chefs always make sure to measure? *(They always make sure to measure butter and other fats, sugar, flour, eggs, and leavenings such as baking soda and baking powder. They may use approximate measurements for salt and flavorings.)* Point out that the ingredients which are measured are those that must be present in specific ratios in order for the finished product to turn out successfully. For example, cookies need to have butter and sugar present in a different ratio than a cake does. Explain that when a chef creates a new recipe for a baked good, he or she uses science and math to determine the amounts of the basic ingredients in the new creation. Then, he or she is free to use creativity to develop a distinctive new flavor. Knowing baking ratios allows television chefs who compete in cook-offs to confidently create a cake, a custard, cookies, a pastry, or a bread without referring to a recipe.

CHEMYSTERY ANSWERS

86. 3.75 cups flower; 3 eggs

87. **BIG**IDEA When Jack added more sugar than the recipe called for, the sugar became an excess reagent and all the other ingredients were limiting reagents.

ASSESSMENT

Answers

88. a. 22, 22, 25
b. 50, 50, 70
c. 8, 8, 10
d. 12, 12, 14

89. a. ultraviolet
b. ultraviolet
c. ultraviolet

90. a. sodium
b. arsenic
c. cesium

91. a. Cs·
b. :$\ddot{\text{Br}}$·
c. ·Ca·
d. ·$\ddot{\text{P}}$·

92. c and d

93. single bond, one pair of shared electrons; double bond, two pairs of shared electrons; triple bond, three pairs of shared electrons

94. Yes, an ionic compound with at least one polyatomic ion has covalent bonds.

95. A cation has a positive charge, and an anion has a negative charge.

96. a. phosphate ion
b. aluminum ion
c. selenide ion
d. ammonium ion

97. a. silicon dioxide
b. potassium sulfate
c. carbonic acid
d. magnesium sulfide

98. a. $Al_2(CO_3)_3$
b. NO_2
c. K_2S
d. $MnCrO_4$
e. NaBr

99. 7.38 g Be

100. 1.30×10^{-22} g

101. $C_2H_2O_4$

102. a. 0.473 mol KNO_3
b. 9.91×10^{-2} mol SO_2
c. 3.74×10^{-2} mol PCl_3

103. a. $2Pb(NO_3)_2 \rightarrow 2PbO + 4NO_2 + O_2$
b. $2C_3H_7OH + 9O_2 \rightarrow 6CO_2 + 8H_2O$
c. $2Al + 3FeO \rightarrow 3Fe + Al_2O_3$

104. a. 1, 1, 1, 2
b. 1, 3, 3, 1
c. 1, 1, 1, 2

105. a. $Ba^{2+}(aq) + SO_4^{2-}(aq) \rightarrow BaSO_4(s)$
b. $Ag^{+}(aq) + Cl^{-}(aq) \rightarrow AgCl(s)$
c. $H^{+}(aq) + OH^{-}(aq) \rightarrow H_2O(l)$

106. a. sodium ion and nitrate ion
b. aluminum ion and nitrate ion
c. magnesium ion and sulfate ion

107. $C_5H_{10}O_5 + 5O_2 \rightarrow 5CO_2 + 5H_2O$

Cumulative Review

***88.** How many electrons, protons, and neutrons are in an atom of each isotope?
a. titanium-47
b. tin-120
c. oxygen-18
d. magnesium-26

89. When comparing ultraviolet and visible electromagnetic radiation, which has
a. a higher frequency?
b. a higher energy?
c. a shorter wavelength?

90. Identify the larger atom of each pair.
a. sodium and chlorine
b. arsenic and nitrogen
c. fluorine and cesium

91. Write electron dot formulas for the following atoms:
a. Cs **c.** Ca
b. Br **d.** P

92. Which of these elements form ions with a 2+ charge?
a. potassium
b. sulfur
c. barium
d. magnesium

93. Distinguish among single, double, and triple covalent bonds.

94. Can a compound have both ionic and covalent bonds? Explain your answer.

95. How do you distinguish between a cation and an anion?

96. Name these ions.
a. PO_4^{3-} **c.** Se^{2-}
b. Al^{3+} **d.** NH_4^{+}

97. Name each substance.
a. SiO_2 **c.** H_2CO_3
b. K_2SO_4 **d.** MgS

98. Write the formula for each compound.
a. aluminum carbonate
b. nitrogen dioxide
c. potassium sulfide
d. manganese(II) chromate
e. sodium bromide

***99.** How many grams of beryllium are in 147 g of the mineral beryl ($Be_3Al_2Si_6O_{18}$)?

100. What is the mass, in grams, of a molecule of benzene (C_6H_6)?

***101.** What is the molecular formula of oxalic acid, molar mass 90 g/mol? Its percent composition is 26.7% C, 2.2% H, and 71.1% O.

102. How many moles is each of the following?
a. 47.8 g KNO_3
b. 2.22 L SO_2 (at STP)
c. 2.25×10^{22} molecules PCl_3

103. Write a balanced chemical equation for each reaction.
a. When heated, lead(II) nitrate decomposes to form lead(II) oxide, nitrogen dioxide, and molecular oxygen.
b. The complete combustion of isopropyl alcohol (C_3H_7OH) produces carbon dioxide and water vapor.
c. When a mixture of aluminum and iron(II) oxide is heated, metallic iron and aluminum oxide are produced.

104. Balance each equation.
a. $Ba(NO_3)_2(aq) + Na_2SO_4(aq) \longrightarrow BaSO_4(s) + NaNO_3(aq)$
b. $AlCl_3(aq) + AgNO_3(aq) \longrightarrow AgCl(s) + Al(NO_3)_3(aq)$
c. $H_2SO_4(aq) + Mg(OH)_2(aq) \longrightarrow MgSO_4(aq) + H_2O(l)$

105. Write a net ionic equation for each reaction in Problem 104.

106. Identify the spectator ions in each reaction in Problem 104.

107. Write a balanced chemical equation for the complete combustion of ribose, $C_5H_{10}O_5$.

Standards: C.1.6, C.4.2, C.4.3, C.4.4

Tips for Success

Anticipate the answer. Use what you know to predict what you think the answer should be. Then look to see if your answer, or one much like it, is given as an option.

Select the choice that best answers each question or completes each statement.

1. Nitric acid is formed by the reaction of nitrogen dioxide with water.

$$3NO_2(g) + H_2O(l) \longrightarrow NO(g) + 2HNO_3(aq)$$

How many moles of water are needed to react with 8.4 mol NO_2?

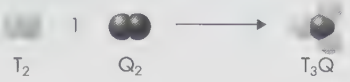
(A) 2.8 mol **(C)** 8.4 mol
(B) 3.0 mol **(D)** 25 mol

2. Phosphorus trifluoride is formed from its elements.

$$P_4(s) + 6F_2(g) \longrightarrow 4PF_3(g)$$

How many grams of fluorine are needed to react with 6.20 g of phosphorus?

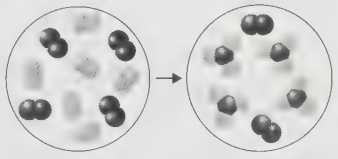
(A) 2.85 g **(C)** 11.4 g
(B) 5.70 g **(D)** 37.2 g



3. Magnesium nitride is formed in the reaction of magnesium metal with nitrogen gas.

$$3Mg(s) + N_2(g) \longrightarrow Mg_3N_2(s)$$

The reaction of 4.0 mol of nitrogen with 6.0 mol of magnesium produces



(A) 2.0 mol of Mg_3N_2 and no excess N_2.
(B) 2.0 mol of Mg_3N_2 and 2.0 mol of excess N_2.
(C) 4.0 mol of Mg_3N_2 and 1.0 mol of excess Mg.
(D) 6.0 mol of Mg_3N_2 and 3.0 mol of excess N_2.

Use the reaction below to answer Questions 4 and 5.

4. Write a balanced equation for the reaction between element T and element Q.

5. Based on the atomic windows below, identify the limiting reagent.

For each question, there are two statements. Decide whether each statement is true or false. Then decide whether Statement II is a correct explanation for Statement I.

	Statement I		Statement II
6.	Every stoichiometry calculation uses a balanced equation.	**BECAUSE**	Every chemical reaction obeys the law of conservation of mass.
7.	A percent yield is always greater than 0% and less than 100%.	**BECAUSE**	The actual yield in a reaction is never more than the theoretical yield.
8.	The amount of the limiting reagent left after a reaction is zero.	**BECAUSE**	The limiting reagent is completely used up in a reaction.
9.	The coefficients in a balanced equation represent the relative masses of the reactants and products.	**BECAUSE**	The mass of the reactants must equal the mass of the products in a chemical reaction.
10.	A mole ratio is always written with the larger number in the numerator.	**BECAUSE**	A mole ratio will always be greater than 1.

Materials List

For the Student

Small-Scale Lab, p 435
- plastic Petri dish
- water
- ice
- rubbing alcohol
- calcium chloride
- graph paper (1-cm cycle)
- bromothymol blue solution
- vinegar
- aqueous ammonia

Quick Lab, p 437
- small pieces of solid air freshener
- small shallow container
- 2 clear plastic cups (8 oz each)
- hot tap water
- ice
- 3 thick cardboard strips

For the Teacher

Teacher Demo, p 421
- Newtonian cradle

Teacher Demo, p 422
- empty aluminum beverage can
- water
- hot plate
- foil or other material for sealing opening of can

Class Activity, p 423
- cardboard containers (such as half-pint milk cartons)
- ball bearings

Teacher Demo, p 427
- manometer
- 1-L flask with 2-hole stopper
- separatory funnel
- short piece of glass tubing bent at a 90° angle
- rubber hose
- 50 mL acetone
- ice water

Teacher Demo, p 428
- 2 cotton balls
- water
- rubbing alcohol

Class Activity, p 429
- thermometer
- beaker
- water
- ring stand
- thermometer clamp
- hot plate

Class Activity, p 432
- samples of wallpaper with repeating patterns

Teacher Demo, p 433
- dishwashing detergent
- watch glass
- overhead projector
- drinking straw

Hot, liquid lava flows from a volcano. When it cools to a solid, new rock will be formed.

Focus on ELL

1 CONTENT AND LANGUAGE Have students follow along as you read the lesson titles and Essential Questions out loud. Then write the word *nature* on the board and explain that it has many meanings. Have students use the lesson titles and Essential Questions to formulate their own definition of *nature* as it is used in the lesson titles.

BEGINNING: LOW/HIGH If literate, translate the lesson titles and Essential Questions into students' native language. Provide students with a simplified English definition of the term *nature*.

INTERMEDIATE: LOW/HIGH Have students use context clues in the lesson titles and Essential Questions to develop their own definition for the term *nature*.

ADVANCED: LOW/HIGH Have students look up the definitions of the term *nature* in the dictionary. Have them use context clues from the lesson titles and Essential Questions to determine which definition is best suited for the term in this context.

BIG IDEA

KINETIC THEORY

Essential Questions:

1. *What factors determine the physical state of a substance?*
2. *What are the characteristics that distinguish gases, liquids, and solids?*
3. *How do substances change from one state to another?*

CHEMYSTERY

Foggy Car Windows

It's a cold, rainy day in September, and you and a friend are heading out to a movie. When you first get into your mom's car, you can clearly see nearby trees swaying in the wind. But shortly after your mom starts the car, the glass fogs up, making it almost impossible to see outside. Your mom sighs, and turns on the heat, which only makes the foggy windows worse. Then she turns on the air conditioner, and the fog is gone in seconds. Why do car windows fog up when it is cold or raining outside? Why does the fog go away when you turn on the air conditioner?

▶ Connect to the BIG IDEA As you read about states of matter, think about what might cause car windows to fog.

INDIANA'S ACADEMIC STANDARDS FOR SCIENCE

Properties and States of Matter C.1.5; **Thermochemistry** C.6.1, C.6.2. See lessons for details.

Introduce the Chapter

IDENTIFYING PRECONCEPTIONS Students may have not have considered that substances can change from one state to another at temperatures other than their boiling points and melting points, and that these points can vary. Use the activities to introduce these concepts.

Activity 1 *You will need pea-sized bits of dry ice, a beaker with water, insulated gloves, and tongs.* As students watch, use tongs to drop bits of dry ice into the water. Students will see the bits swirl as the dry ice becomes warmer and forms carbon dioxide gas. Explain that the solid is changing to a gas by sublimation.

Activity 2 **Ask** At what temperature does liquid water change to water vapor? *(Students may say 100°C.)* Point out that water also changes to a gas by evaporation at any temperature. Have students slightly dampen a sheet of paper and observe it after a day. The paper will be dry because the water evaporated.

UbD

Understanding By Design

Students are building toward understanding states of matter by relating them to the kinetic theory of matter.

PERFORMANCE GOALS At the end of Chapter 13, students will be able to answer the essential questions by applying their knowledge of states of matter. Students will also be able to convert between different units of pressure.

ESSENTIAL QUESTIONS Read the essential questions aloud. **Ask** Why are solids, liquids, and gases called physical states and not chemical states? *(If a substance changes from one state to another, only its physical properties change. It still has the same chemical makeup.)* **Ask** Is the temperature at which a substance changes from one state to another always the same? Explain. *(No. The temperature at which a substance changes state depends on both temperature and pressure.)*

BIG IDEA Use the photo of a lava flow to help students connect to the concepts they will learn in this chapter. Activate prior knowledge by discussing the properties of the lava. **Ask** What are the two states of matter you can see in the photo? *(solid and liquid)* **Ask** How are the properties of the solid and liquid lava different? *(The solid is hard, cannot flow, and has a fixed shape. The liquid is not hard and can flow. Its shape changes and it is hotter than the solid.)*

CHEMYSTERY Have students read over the CHEMystery. Connect the CHEMystery to the Big Idea of Kinetic Theory by explaining that the state of matter depends on how the particles of a substance move. Ask students to predict why the fog on the car windows goes away when the air conditioner is turned on. As a hint, suggest that students think about how much water the air can hold at different temperatures.

LESSON 13.1

Key Objectives

13.1.1 DESCRIBE the three assumptions of the kinetic theory as it applies to gases.

13.1.2 INTERPRET gas pressure in terms of kinetic theory.

13.1.3 DEFINE the relationship between the temperature in kelvins and the average kinetic energy of particles.

CHEMISTRY & YOU Display a weather map from your local paper and explain what the symbols represent. Ask student volunteers to interpret the map and predict the weather for the week. **Ask** What type of weather can you expect if the map shows a dry, cold air mass moving into your area during the summer? *(cool temperatures, dry air, and clear skies)* Explain that winds often blow from areas of high pressure towards areas of low pressure. **Ask** What causes pockets of air in Earth's atmosphere to have different pressures? *(uneven heating of Earth's surface)*

IN ACADEMIC STANDARDS for SCIENCE

C.1.5 Describe the characteristics of solids, liquids, and gases and state changes at the molecular level.

C.6.1 Explain that atoms and molecules that make up matter are in constant motion and that this motion increases as thermal energy increases.

Also covered C.6.2.

13.1 The Nature of Gases

C.1.5 States of matter; C.6.1 Explain that atoms and molecules are in constant motion; C.6.2 Distinguish between temperature and heat flow

CHEMISTRY & YOU

Q: *What factors most strongly affect the weather?* The atmosphere is a gas, and the factors that determine the behavior of gases—temperature and pressure—affect the weather in the atmosphere. That is why weather maps show temperature readings and areas of high and low pressure. In this lesson, you will learn how temperature and pressure affect the particles of a gas.

Key Questions

- *What are the three assumptions of the kinetic theory as it applies to gases?*
- *How does kinetic theory explain gas pressure?*
- *What is the relationship between the temperature in kelvins and the average kinetic energy of particles?*

Vocabulary

- kinetic energy
- kinetic theory
- gas pressure
- vacuum
- atmospheric pressure
- barometer
- pascal (Pa)
- standard atmosphere (atm)

Kinetic Theory and a Model for Gases

What are the three assumptions of the kinetic theory as it applies to gases?

The word *kinetic* refers to motion. The energy an object has because of its motion is called **kinetic energy.** According to the **kinetic theory,** all matter consists of tiny particles that are in constant motion. The particles in a gas are usually molecules or atoms. The kinetic theory as it applies to gases includes the following fundamental assumptions about gases.

The particles in a gas are considered to be small, hard spheres with an insignificant volume. Within a gas, the particles are relatively far apart compared with the distance between particles in a liquid or solid. Between the particles, there is empty space. No attractive or repulsive forces exist between the particles.

The motion of the particles in a gas is rapid, constant, and random. As a result, gases fill their containers regardless of the shape and volume of the containers. An uncontained gas can spread out into space without limit. The particles travel in straight-line paths until they collide with another particle, or another object, such as the wall of their container. The particles change direction only when they rebound from collisions with one another or with other objects.

Measurements indicate that the average speed of oxygen molecules in air at 20°C is an amazing 1700 km/h! At these high speeds, the odor from a hot cheese pizza in Washington, D.C., should reach Mexico City in about 115 minutes. That does not happen, however, because the molecules responsible for the odor are constantly striking molecules in air and rebounding in other directions. Their path of uninterrupted travel in a straight line is very short. The aimless path the molecules take is called a random walk.

All collisions between particles in a gas are perfectly elastic. During an elastic collision, kinetic energy is transferred without loss from one particle to another, and the total kinetic energy remains constant. The diagrams in Figure 13.1 illustrate the assumptions of kinetic theory as applied to gases.

Focus on ELL

1 CONTENT AND LANGUAGE Assign small groups one content vocabulary term. Groups should prepare a learning tool for the class. This tool should show how to pronounce the assigned vocabulary term and provide a meaning for it. Encourage groups to use word-analysis strategies, pronunciation spelling, vowel patterning, sounds-like clues, and illustrations. Groups should present their learning tool to the class and address common misinterpretations and mispronunciations of their assigned word

2 FRONTLOAD THE LESSON Engage students in a discussion of what they already know about gases. Discuss why the intensity of odors vary depending on proximity to the source. Discuss the danger of odorless gases, such as carbon monoxide. Finally, point out that gasoline used in cars is often referred to as *gas,* but it is actually a liquid.

3 COMPREHENSIBLE INPUT Use Figure 13.1 to introduce properties of gases. Explain that by considering the small scale action of individual gas particles students can get a sense of the large scale action of a gas.

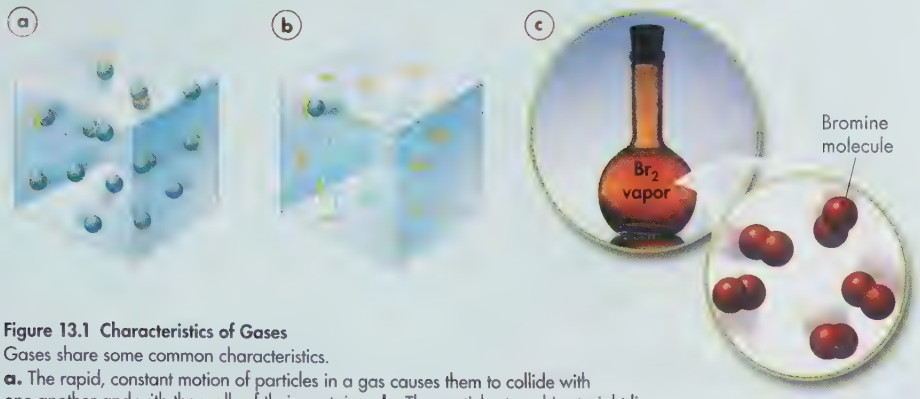

Figure 13.1 Characteristics of Gases
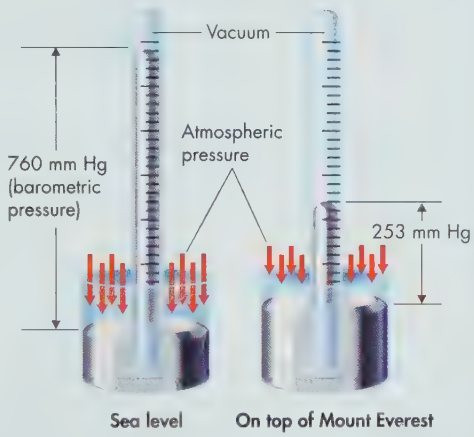
Gases share some common characteristics.
a. The rapid, constant motion of particles in a gas causes them to collide with one another and with the walls of their container. **b.** The particles travel in straight-line paths between collisions. **c.** A gas fills all the available space in its container.
Relate Cause and Effect *Why don't the particles in a gas eventually slow down and stop?*

Gas Pressure



How does kinetic theory explain gas pressure?

A balloon filled with helium or hot air maintains its shape because of the pressure of the gas within it. **Gas pressure** results from the force exerted by a gas per unit surface area of an object. What causes this force? Moving bodies exert a force when they collide with other bodies. Although a single particle in a gas is a moving body, the force it exerts is extremely small. Yet it is not hard to imagine that simultaneous collisions involving many particles would produce a measurable force on an object. **Gas pressure is the result of billions of rapidly moving particles in a gas simultaneously colliding with an object.** If no particles are present, no collisions can occur. Consequently, there is no pressure. An empty space with no particles and no pressure is called a **vacuum.**

You are already familiar with a gas pressure caused by a mixture of gases—air. Air exerts pressure on Earth because gravity holds the particles in air within Earth's atmosphere. The collisions of atoms and molecules in air with objects results in **atmospheric pressure.** Atmospheric pressure decreases as you climb a mountain because the density of Earth's atmosphere decreases as the elevation increases.

A **barometer** is a device that is used to measure atmospheric pressure. Figure 13.2 shows an early type of mercury barometer. The height of the mercury column in the tube depends on the pressure exerted by particles in air colliding with the surface of the mercury in the dish. Atmospheric pressure depends on weather and on altitude. In fair weather at sea level, the atmospheric pressure is sufficient to support a mercury column 760 mm high.

Figure 13.2 Atmospheric Pressure
At sea level, air exerts enough pressure to support a 760-mm column of mercury. On top of Mount Everest, at 9000 m, the air exerts only enough pressure to support a 253-mm column of mercury.

Differentiated Instruction

ELL ENGLISH LANGUAGE LEARNERS Have available the weather section of the local newspaper, and the weather reports from students' native cities. Help students determine the day's pressure, in all locations, in units of mm Hg, kPa, and atm, and to compare data. Students may wish to track the daily pressure and display the changes on a graph.

L1 STRUGGLING STUDENTS To help convey the meaning of the word *kinetic*, show a video of kinetic sculptures created by sculptor Theo Jansen. Challenge students to create a kinetic sculpture that reflects the concepts in this lesson.

L3 ADVANCED STUDENTS Unlike traditional barometers, aneroid barometers do not balance atmospheric pressure against a liquid of known density. In fact, they contain no liquid and are independent of gravity. If possible, bring one to class and explain its components. Have interested students research the advantages of aneroid barometers. *(They are compact, self enclosed, and easily transported. They can operate under conditions not suited to mercury barometers.)*

Explain

Kinetic Theory and a Model for Gases

USE VISUALS Direct students to Figure 13.1. Be sure students understand that the space between the gas particles is not filled with air or any other substance. Help students visualize that the pressure of a gas is caused by collisions of the particles with the walls of the container; point out that the magnitude of the pressure is related to how often and how hard the particles strike the walls.

Explore

Gas Pressure

Teacher Demo

PURPOSE Students will observe and differentiate elastic collisions from perfectly elastic collisions.

MATERIALS Newtonian cradle (a device in which small steel balls are suspended by thin nylon tethers to horizontal wooden sticks)

PROCEDURE Explain that in an elastic collision, kinetic energy is transferred between the objects that collide. In a perfectly elastic collision, the total amount of kinetic energy remains constant. Then pull back one of the balls and let it fall into the other balls. Let the balls come to rest. **Ask** Were the collisions between the balls elastic? *(Yes, because kinetic energy was transferred with each collision.)* **Ask** Why did the balls eventually stop moving? *(The collisions were not perfectly elastic; some kinetic energy was lost as heat during each collision.)* Remind students that the kinetic theory assumes that all collisions between particles in a gas are perfectly elastic. (Note: In Chapter 14, students will learn that the assumptions of the kinetic theory do not hold true for real gases under all conditions.)

Explain

USE VISUALS Direct students to Figure 13.2. Point out the parts of the barometer and explain how the barometer is used to measure atmospheric pressure. **Ask** What is the decrease in pressure from sea level to the top of Mount Everest in kPa? *(507 mm Hg)*

Answers

FIGURE 13.1 The particles in a gas collide elastically meaning that the total amount of kinetic energy remains constant, and the particles do not slow down and stop.

Explore

Gas Pressure

CHEMISTRY & YOU The height of the mercury column in a barometer decreases as a storm approaches because the atmospheric pressure decreases

Sample Practice Problem

A. What pressure, in mm Hg and atm, does a sample of neon gas exert at 75.0 kPa? *(563 mm Hg, 0.740 atm)*

B. What pressure, in mm Hg and kPa, does a sample of argon gas exert at 1.561 atm? *(1186 mm Hg, 158.1 kPa)*

Explore

Teacher Demo

PURPOSE Students will become aware of the tremendous pressure exerted by Earth's atmosphere.

MATERIALS empty aluminum beverage can, water, hot plate, foil or other material for sealing opening of can

PROCEDURE Explain to students that they live at the bottom of a very deep "ocean" of air. Fill an empty aluminum beverage container with water to a depth of about 1 to 2 cm. Set the can on a hot plate and bring the water to a boil. Allow the water to boil vigorously for several minutes. Remove the can from the heat source, seal the opening, and allow the can to cool at room temperature or invert the can in a pan of cool water.

EXPECTED OUTCOME Once the water vapor inside the can condenses, the atmospheric pressure will crush the can. Ask students to interpret their observations.

CHEMISTRY & YOU

Q: *When weather forecasters state that a low-pressure system is moving into your region, it usually means that a storm is coming. What do you think happens to the column of mercury in a barometer as a storm approaches? Why?*

The SI unit of pressure is the **pascal (Pa).** It represents a very small amount of pressure. For example, normal atmospheric pressure is about 100,000 Pa, that is, 100 kilopascals (kPa). Two older units of pressure are still commonly used. These units are millimeters of mercury (mm Hg) and atmospheres. One **standard atmosphere (atm)** is the pressure required to support 760 mm of mercury in a mercury barometer at 25°C. The numerical relationship among the three units is

$$1 \text{ atm} = 760 \text{ mm Hg} = 101.3 \text{ kPa}$$

When studying gases, it is important to be able to relate measured values to standards. Recall that the standard temperature and pressure (STP) are defined as a temperature of 0°C and a pressure of 101.3 kPa, or 1 atm.

Sample Problem 13.1

Converting Between Units of Pressure

A pressure gauge records a pressure of 450 kPa. Convert this measurement to

a. atmospheres. **b.** millimeters of mercury.

KNOWNS
pressure = 450 kPa
1 atm = 101.3 kPa
1 atm = 760 mm Hg

UNKNOWNS
pressure = ? atm
pressure = ? mm Hg

1 Analyze **List the knowns and the unknowns.** The given pressure is converted into the desired unit by multiplying by the proper conversion factor.

2 Calculate **Solve for the unknowns.**

Identify the appropriate conversion factor to convert kPa to atm.

a. $\frac{1 \text{ atm}}{101.3 \text{ kPa}}$

Multiply the given pressure by the conversion factor.

$450 \text{ kPa} \times \frac{1 \text{ atm}}{101.3 \text{ kPa}} = 4.4 \text{ atm}$

Identify the appropriate conversion factor to convert kPa to mm Hg.

b. $\frac{760 \text{ mm Hg}}{101.3 \text{ kPa}}$

Multiply the given pressure by the conversion factor.

$450 \text{ kPa} \times \frac{760 \text{ mm Hg}}{101.3 \text{ kPa}} = 3400 \text{ mm Hg} = 3.4 \times 10^3 \text{ mm Hg}$

3 Evaluate **Do the results make sense?** Because the first conversion factor is much less than 1 and the second is much greater than 1, it makes sense that the values expressed in atm and mm Hg are respectively smaller and larger than the value expressed in kPa.

1. What pressure, in kilopascals and in atmospheres, does a gas exert at 385 mm Hg?

2. The pressure at the top of Mount Everest is 33.7 kPa. Is that pressure greater or less than 0.25 atm?

Foundations for Math

CHECKING ANSWERS Remind students that scientists check their answers when making conversions to be sure they are reasonable. This is an especially important step when working with measurements that can be converted between more than one acceptable unit of measurement.

In **Sample Problem 13.1,** answers are evaluated in relation to the conversion factor used for each calculation. For part **a**, 450 kPa is being divided by a value of just over 100, so it is reasonable to expect a value approximately equal to 4.5 atm. In part **b**, 450 kPa is being multiplied by a factor of approximately 7.6. Because 7.6 rounds to 8, it is reasonable to expect an answer of approximately 3600 mm Hg. The actual answer, 3.4×10^3 mm Hg, is reasonable because 7.6 is less than 8.

Kinetic Energy and Temperature

What is the relationship between the temperature in kelvins and the average kinetic energy of particles?

As a substance is heated, its particles absorb energy, some of which is stored within the particles. This stored portion of the energy, or potential energy, does not raise the temperature of the substance. The remaining absorbed energy does speed up the particles—that is, increases their kinetic energy. This increase in kinetic energy results in an increase in temperature.

Average Kinetic Energy The particles in any collection of atoms or molecules at a given temperature have a wide range of kinetic energies. Most of the particles have kinetic energies somewhere in the middle of this range. Therefore, we use average kinetic energy when discussing the kinetic energy of a collection of particles in a substance. At any given temperature, the particles of all substances, regardless of physical state, have the same average kinetic energy. For example, the ions in table salt, the molecules in water, and the atoms in helium all have the same average kinetic energy at room temperature, even though the three substances are in different physical states.

Figure 13.3 shows the distribution of kinetic energies of water molecules at two different temperatures. The green curve shows the distribution of kinetic energy among the water molecules in cold water. The purple curve shows the distribution of kinetic energy among the water molecules in hot water. In both cases, most of the molecules have intermediate kinetic energies, which are close to the average value. Notice that molecules at the higher temperature have a wider range of kinetic energies.

The average kinetic energy of the particles in a substance is directly related to the substance's temperature. An increase in the average kinetic energy of the particles causes the temperature of a substance to rise. As a substance cools, the particles tend to move more slowly, and their average kinetic energy decreases.

READING SUPPORT

Build Vocabulary:
Word Origins Kinetic comes from the greek word *kinetos*, meaning "to move." Kinetic energy is the energy an object has because of its motion. ***Some sculptures are kinetic. What characteristic do they share?***

Interpret Graphs

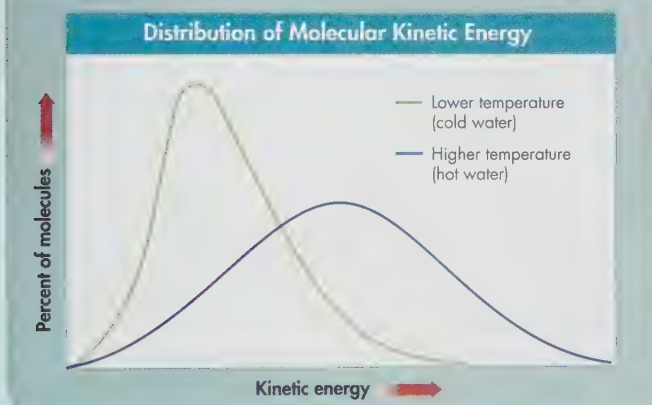


Figure 13.3 The green and purple curves show the kinetic energy distributions of a typical collection of molecules at two different temperatures.
a. Infer Which point on each curve represents the average kinetic energy?
b. Compare and Contrast Compare the shapes of the curves for cold water and hot water.
c. Predict What would happen to the shape of the curve if the water temperature were even higher? Even lower?

UbD Check for Understanding

How does kinetic theory explain gas pressure?

To assess students' understanding of the kinetic theory, ask them to work in pairs and to create a scenario that is analogous to the kinetic theory. Have each pair illustrate in a diagram what happens to 'gas particles' in their scenario when conditions such as pressure and temperature change.
(check students' diagram)

ADJUST INSTRUCTION If students have difficulty creating or diagramming their scenarios, have them create a bulleted list of facts about the kinetic theory as it relates to gas pressure and temperature. Then provide students with additional practice where they can reference their list to describe the behavior of gas particles under conditions of varying pressure and temperature such as those described in the text.

Explain

Kinetic Energy and Temperature

CRITICAL THINKING Direct students to Figure 13.1. **Ask** What does the intersection point of the green and purple curves indicate? *(The particles have the same kinetic energy.)*

Explore

Class Activity

PURPOSE Students will be able to visualize what is happening in a gas as the average kinetic energy increases.

MATERIALS cardboard containers (e.g., half-pint milk cartons), ball bearings

PROCEDURE Give students cardboard boxes containing the same number of ball bearings. Have students shake the boxes slowly at first. Then have them gradually increase the rate of shaking and observe what happens. Tell students that the shaking is analogous to adding energy to the particles in a gas. The greater the rate of the shaking, the more energy is added. Then ask how an increase in energy affects the frequency of collisions.

EXPECTED OUTCOME Student should hear and feel the increase in number of collisions as the rate of shaking (or the amount of energy added) increases.

Answers

1. 51.3 kPa, 0.507 atm
2. 33.7 kPa is greater than 0.25 atm

READING SUPPORT A kinetic sculpture has moving parts. Some are free-hanging mobiles; some are stabiles with motors.

FIGURE 13.3

a. a point near the peak of the curve
b. The curves have the same overall shape, but the curve for hot water is wider with a lower peak.
c. At an even higher temperature, the graph would be wider than the purple curve with a lower peak; at an even lower temperature, the graph would be narrower than the green curve with a higher peak.

Extend

Connect to ASTRONOMY

Astronomers classify nebulae into two broad categories—bright and dark. Bright nebulae are close enough to stars that they glow. Dark nebulae are illuminated only if something bright, like a star cluster, is in the background. Dark nebulae are the sites of star birth while bright nebulae are the sites star death. But nebulae do not stay in one category or the other forever. For example, once a star is born, a dark nebula changes into a bright nebula. There are several types of dark and bright nebulae. These nebulae are named for their physical appearance and/or chemical makeup. The boomerang nebula shown in Figure 13.4 is a type of bright nebulae called a planetary nebula. Planetary nebulae are named for their round shape and resemblance to planets. An emission nebula is another type of bright nebula. Have interested students research why an emission nebula is so named. Then have them compare and contrast emission nebulae to planetary nebulae.

Evaluate

Informal Assessment

To assess students' comprehension of kinetic theory as it applies to gases, pose the following questions.

Ask What is kinetic energy? *(energy due to the motion of an object)* **Ask** How is the average kinetic energy of a collection of particles related to temperature? *(Average kinetic energy is directly proportional to the Kelvin temperature. Higher temperatures reflect a greater average kinetic energy.)*

Then direct students to complete 13.1 Lesson Check

Reteach

Have students look at Figure 13.3 again. Point out that the distribution of kinetic energy in cold water is represented by the green curve. Point out that the distribution of kinetic energy in hot water is represented by the purple curve. **Ask** In which sample is the average kinetic energy of the particles higher? *(hot water)* Explain how this graph applies to gases.

Figure 13.4
The Coldest Place in the Universe
The boomerang nebula is the coldest known region of space. A nebula is a large cloud of gas and dust spread out in an immense volume. Gases are moving rapidly away from a dying star at the center of this nebula. The rapid expansion of these gases is the reason why this nebula is so cold.

You could reasonably expect the particles of all substances to stop moving at some very low temperature. The particles would have no kinetic energy at that temperature because they would have no motion. Absolute zero (0 K, or −273.15°C) is the temperature at which the motion of particles theoretically ceases. No temperature can be lower than absolute zero. Absolute zero has never been produced in the laboratory. However, a near-zero temperature of about 0.000 000 000 1 K (0.1×10^{-9} K), which is 0.1 nanokelvin, has been achieved. The coldest temperatures recorded outside of the laboratory are from space. In 1995, astronomers used a radio telescope to measure the temperature of the boomerang nebula shown in Figure 13.4. At a temperature of about 1 K, it is the coldest known region of space.

Average Kinetic Energy and Kelvin Temperature The Kelvin temperature scale reflects the relationship between temperature and average kinetic energy. **The Kelvin temperature of a substance is directly proportional to the average kinetic energy of the particles of the substance.** For example, the particles in helium gas at 200 K have twice the average kinetic energy as the particles in helium gas at 100 K. The effects of temperature on particle motion in liquids and solids are more complex than in gases.

13.1 LessonCheck

3. Describe Briefly describe the assumptions of kinetic theory as applied to gases.

4. Explain Use kinetic theory to explain what causes gas pressure.

5. Explain How is the Kelvin temperature of a substance related to the average kinetic energy of its particles?

6. Apply Concepts Describe the behavior of an oxygen molecule in a sealed container of air. Include what happens when the molecule collides with another molecule or the container walls.

7. Calculate Convert the following pressures to kilopascals.
a. 0.95 atm **b.** 45 mm Hg

8. Predict A cylinder of oxygen gas is cooled from 300 K (27°C) to 150 K (−123°C). By what factor does the average kinetic energy of the oxygen molecules in the cylinder decrease?

BIG IDEA KINETIC THEORY

9. Why does a gas take the shape and volume of its container?

Lesson Check Answers

3. A gas is composed of tiny particles whose motion is rapid, constant, and random. Collisions between particles are perfectly elastic.

4. Gas pressure is the result of simultaneous collisions of billions of rapidly moving particles with an object.

5. The Kelvin temperature is directly proportional to the average kinetic energy of the particles.

6. The oxygen molecule moves in straight-line random motion until it collides with another molecule or with the side of the container. After a collision, the direction of the motion changes.

7. **a.** 96 kPa
b. 6.0 kPa

8. by one-half

9. **BIG IDEA** As gas particles move, they spread apart filling all available space.

13.2 The Nature of Liquids

C.1.5 States of matter; C.3.3 Chemical bonds and intermolecular attractions; C.6.1 Explain that atoms and molecules are in constant motion; C.6.2 Distinguish between temperature and heat flow

CHEMISTRY & YOU

Q: *How hot should water be when you make coffee?* Ground coffee beans contain many different oils, which contribute to the flavor and aroma of the brew. If the water used for brewing the coffee is too hot, some of these oils vaporize and escape into the air, leaving the coffee less rich and flavorful. For this reason, you should let boiling water cool a little before using it to brew your coffee. In this section, you will learn why different liquids have different boiling points.

Key Questions

- *What factors determine the physical properties of a liquid?*
- *What is the relationship between evaporation and kinetic energy?*
- *When can a dynamic equilibrium exist between a liquid and its vapor?*
- *Under what conditions does boiling occur?*

Vocabulary

- vaporization
- evaporation
- vapor pressure
- boiling point
- normal boiling point

A Model for Liquids

What factors determine the physical properties of a liquid?

According to the kinetic theory, both the particles in gases and the particles in liquids have kinetic energy. This energy allows the particles in gases and liquids to flow past one another, as shown in Figure 13.5. Substances that can flow are referred to as fluids. The ability of gases and liquids to flow allows them to conform to the shape of their containers.

Gases and liquids have a key difference between them. According to the kinetic theory, there are no attractions between the particles in a gas. However, the particles in a liquid are attracted to each other. These intermolecular attractions keep the particles in a liquid close together, which is why liquids have a definite volume. **The interplay between the disruptive motions of particles in a liquid and the attractions among the particles determines the physical properties of liquids.**

Intermolecular attractions reduce the amount of space between the particles in a liquid. Thus liquids are much more dense than gases. Increasing the pressure on a liquid has hardly any effect on its volume. The same is true for solids. Therefore, liquids and solids are known as condensed states of matter.

Figure 13.5
Comparing Liquids and Gases
Both liquids and gases can flow. The liquid on the left is colored water. The gas on the right is bromine vapor. If a gas is denser than air, it can be poured from one container into another. These pictures were taken in a fume hood because bromine is both toxic and corrosive.
Predict *Over time, what will happen to the gas in the uncovered beaker? Explain.*

Focus on ELL

1 CONTENT AND LANGUAGE Read the lesson title and each key question aloud several times, slowly. Have students signal to you when they hear a word they do not understand. Write these words along with the words *factor, property, relationship, dynamic, equilibrium,* and *condition* on the board. Discuss the academic meaning and the contextual meaning of each word. Then help students paraphrase the title and the questions in a way that is meaningful to them.

2 FRONTLOAD THE LESSON Briefly review kinetic theory as it relates to gases. Then, preview Figure 13.5 to bridge the content students studied about gases in Lesson 13.1 with the discussion of liquids in this lesson.

3 COMPREHENSIBLE INPUT Assign several students the role of gas particle, and assign several others the role of liquid particle. Have them act out various properties of liquids and gases for the class.

Key Objectives

13.2.1 IDENTIFY the factors that determine physical properties of a liquid.

13.2.2 DEFINE evaporation in terms of kinetic energy.

13.2.3 DEFINE the conditions under which a dynamic equilibrium can exist between a liquid and its vapor.

13.2.4 IDENTIFY the conditions under which boiling occurs.

- Small-Scale Laboratory Manual, Lab 20

PearsonChem.com

Engage

CHEMISTRY & YOU Explain that in the coffee brewing process, water acts as a solvent. The water passes through the coffee grinds, dissolving soluble solids as it goes, and into the brew. The non-soluble solids remain in the filter. As a class brainstorm factors that may affect control brewing results. *(Sample answers: the ratio of water-to-coffee; the particle size of the coffee; the temperature of the water; the amount of time water and coffee are in contact with each other; etc.)* **Ask** Why do you think coffee is brewed with hot water? *(water is a better solvent at hot, or near-boiling temperatures)*

IN ACADEMIC STANDARDS for SCIENCE

C.1.5 Describe the characteristics of solids, liquids, and gases and state changes at the molecular level.

C.6.1 Explain that atoms and molecules that make up matter are in constant motion and that this motion increases as thermal energy increases.

Also covered C.3.3, C.6.2.

Answers

FIGURE 13.5 It will disperse in the surrounding air.

Activate Prior Knowledge

Have students create a two column table, one column titled *Gases* and the other *Liquids*. Have students list everything they know about gases, including properties, characteristics, behavior regarding pressure and temperature changes, units of measure, and kinetic theory. Then have students predict how liquids will compare to gases in each category. Have students periodically check the accuracy of their predictions as they proceed with the lesson.

Foundations for Reading

BUILD VOCABULARY After students read the Vapor Pressure section, have them create a concept map using the following terms: *evaporation, condensation, dynamic equilibrium,* and *vapor pressure*.

READING STRATEGY As students read a particular section, have them write two or three real-world scenarios that corresponding to each section on a sticky notes. Tell students to place the sticky notes at each section head.

Explain

A Model for Liquids

USE VISUALS Have students study Figure 13.5. **Ask** How are the colored water and the bromine vapor similar? *(They can both flow and take the shape of their beakers.)* **Ask** How are the water and the bromine vapor different? *(Water has a definite volume. The vapor doesn't have a definite volume.)* **Ask** According to kinetic theory, why doesn't the water spontaneously flow out of the beaker? *(Attractions among water molecules hold the molecules together.)*

Evaporation

USE VISUALS Use the photographs and drawings in Figure 13.6 to compare the evaporation of water in open and closed systems. Make sure students understand the difference between an open and closed system. In an open system, some of the molecules that evaporate from the surface collide with particles in the air and return to the liquid. But because the system is open, all the water molecules will eventually evaporate. In a closed system, the vapor accumulates above the liquid. The amount of vapor will increase until the rates of evaporation and condensation are equal.

Figure 13.6 Open vs. Closed Systems The process of evaporation has a different outcome in an open system, such as a lake or an open container, than in a closed system, such as a terrarium or a sealed container. **a.** In an open system, molecules that evaporate can escape from the system. **b.** In a closed system, the molecules cannot escape. They collect as a vapor above the liquid. Some molecules condense back into a liquid.
Predict *Does the water level change over time in either the open container or the sealed container? Why?*

Evaporation

What is the relationship between evaporation and kinetic energy?

As you probably know, water in an open container, like the one in Figure 13.6a, eventually escapes into the air as water vapor. The conversion of a liquid to a gas or vapor is called **vaporization.** When this conversion occurs at the surface of a liquid that is not boiling, the process is called **evaporation.** Most of the molecules in a liquid don't have enough kinetic energy to overcome the attractive forces and escape into the gaseous state. **During evaporation, only those molecules with a certain minimum kinetic energy can escape from the surface of the liquid.** Even some of the particles that do escape collide with molecules in the air and rebound back into the liquid.

You may have noticed that a liquid evaporates faster when heated. This occurs because heating the liquid increases the average kinetic energy of its particles. The added energy enables more particles to overcome the attractive forces keeping them in the liquid state. As evaporation occurs, the particles with the highest kinetic energy tend to escape first. The particles left in the liquid have a lower average kinetic energy than the particles that have escaped. The process is similar to removing the fastest runner from a race. The remaining runners have a lower average speed. As evaporation takes place, the liquid's temperature decreases. Therefore, evaporation is a cooling process.

You can observe the effects of evaporative cooling on hot days. When you perspire, water molecules in your perspiration absorb heat from your body and evaporate from the skin's surface. This evaporation leaves the remaining perspiration cooler. The perspiration that remains cools you further by absorbing more body heat.

Differentiated Instruction

L3 ADVANCED STUDENTS Have students follow the scientific method to examine whether the surface area of a liquid has an effect on evaporation rate. Tell students to submit a lab report of their hypothesis, procedure, data, and conclusion. Students should conclude that surface area does have an effect on evaporation rate.

ELL ENGLISH LANGUAGE LEARNERS Write the word *evaporate* on the board. Pronounce it slowly and have students repeat. Explain that evaporate comes from the Latin *evaporare,* a term that was formed by combining the Latin prefix *e-*, meaning "out", with the verb form *vaporare*, meaning "to emit vapor". Note that when a liquid evaporates it is emitting a vapor (gas).

L1 SPECIAL NEEDS STUDENTS The amount of visuals used in the lesson could be overwhelming to some students. Consider making individual copies of each visual in the lesson and introducing the concepts one at a time. Modify font size, adjust colors, and rephrase captions if necessary.

Interpret Data

Vapor Pressure (in kPa) of Three Substances at Different Temperatures						
Substance	0°C	20°C	40°C	60°C	80°C	100°C
Water	0.61	2.33	7.37	19.92	47.34	101.33
Ethanol	1.63	5.85	18.04	47.02	108.34	225.75
Diethyl ether	24.70	58.96	122.80	230.65	399.11	647.87

Table 13.1 The table lists vapor pressure values for water, ethanol, and diethyl ether at various temperatures.

a. Analyze At a given temperature, ethanol has a higher vapor pressure than water. What does that say about the relative strength of attraction between particles of each compound?

b. Make Generalizations If a compound has a high vapor pressure, is the relative strength of attraction between particles of the compound large or small?

Vapor Pressure

When can a dynamic equilibrium exist between a liquid and its vapor?

The evaporation of a liquid in a closed system differs from evaporation in an open system. No particles of liquid can escape into the outside air from the sealed container in Figure 13.6b. When a partially filled container of liquid is sealed, some of the particles at the surface of the liquid vaporize. These particles collide with the walls of the sealed container, producing pressure. A measure of the force exerted by a gas above a liquid is called **vapor pressure.** Over time, the number of particles entering the vapor increases and some of the particles condense and return to the liquid state. The following equation summarizes the process.

$$\text{Liquid} \underset{\text{condensation}\leftarrow}{\overset{\text{evaporation}\rightarrow}{\rightleftharpoons}} \text{Vapor (gas)}$$

Eventually, the number of particles condensing will equal the number of particles vaporizing. The vapor pressure will then remain constant. **In a system at constant vapor pressure, a dynamic equilibrium exists between the vapor and the liquid. The system is in equilibrium because the rate of evaporation of liquid equals the rate of condensation of vapor.**

At equilibrium, the particles in the system continue to evaporate and condense, but no net change occurs in the number of particles in the liquid or vapor. The sealed terrarium in Figure 13.6b is an example of a closed system at equilibrium. The moisture on the inner walls of the terrarium is a sign that equilibrium has been established. Particles that once evaporated are condensing, but other particles are evaporating to take their place.

Vapor Pressure and Temperature Change An increase in the temperature of a contained liquid increases the vapor pressure. This happens because the particles in the warmed liquid have increased kinetic energy. As a result, more of the particles will reach the minimum kinetic energy necessary to escape the surface of the liquid. The particles escape the liquid and collide with the walls of the container at a greater frequency. Table 13.1 gives the vapor pressures of some common liquids at various temperatures. The vapor pressure data indicates how volatile a given liquid is, or how easily it evaporates. Of the three liquids shown, diethyl ether is the most volatile and water is the least volatile.

CHEMISTRY & YOU

Q: *To make the best tasting coffee, many people grind the coffee beans just prior to brewing the coffee. Also, they are careful not to grind the coffee beans too much. Explain how both of these methods help prevent the natural oils in coffee beans from vaporizing.*

Differentiated Instruction

L1 STRUGGLING STUDENTS If students are having difficulty grasping the concept of a dynamic equilibrium, try this analogy. There are three students on one side of a room and three students on the other side. One group has 30 foam balls. The other group has none. The balls represent water molecules. Students in the first group begin to toss the balls toward the other group. This action represents evaporation. At first the only process occurring is evaporation. But soon students in the second group begin to toss the balls back. This action represents condensation. When the number of balls being tossed in each direction at any given moment is equal, a dynamic equilibrium exists.

L3 ADVANCED STUDENTS Ask students to use the data in Table 13.1 to construct a graph of vapor pressure versus temperature. They will need to plot the natural log (ln) of P versus $1/T$, where P is the vapor pressure in mm Hg and T is the temperature in kelvins.

Explore

Vapor Pressure

Teacher Demo

PURPOSE Students will observe how the vapor pressure of a liquid changes with temperature.

MATERIALS manometer, 1-L flask with 2-hole stopper, separatory funnel, short piece of glass tubing bent at a 90 angle, rubber hose, 50 mL acetone, ice water

SAFETY To insert the glass tubing in the stopper, use glycerol. Wear gloves or hold the tubing in a towel to protect your hands. Be sure there are no open flames in the room because acetone is flammable.

PROCEDURE You will need to obtain or construct a manometer and assemble the following apparatus. Insert a two-hole stopper into a 1-L flask. Into one hole of the stopper, insert a separatory funnel capable of containing 50 mL of acetone. Insert the bent glass tubing into the other hole. Use a rubber hose to connect the glass tubing to one end of the manometer. Be sure the hose fits both connections tightly. Use the manometer to measure the initial pressure. Then open the valve on the separatory funnel, and let the acetone drain into the flask. Have students observe the pressure in the flask. The maximum pressure observed is the vapor pressure of acetone at room temperature. Next, place the flask in ice water, and have students observe the change in pressure.

EXPECTED OUTCOMES The pressure rises immediately as the acetone flows into the flask. The pressure falls when the flask is cooled.

CHEMISTRY & YOU Grinding the coffee beans increases the surface area of the coffee. A greater surface area increases the rate at which the natural oils in coffee will evaporate. Overgriding the beans will heat the oils also causing them to evaporate.

Answers

FIGURE 13.6 The water level will decrease over time in the open container because the evaporating water molecules can escape from the container.

INTERPRET DATA

a. The strength of attractions between the particles in water is stronger than in diethyl ether.

b. The higher the vapor pressure of a compound is, the weaker is the force of attraction between the particles of the compound.

Explore

Vapor Pressure

Teacher Demo

PURPOSE Students will infer the relative vapor pressures of two liquids.

MATERIALS 2 cotton balls, water, rubbing alcohol

PROCEDURE Use cotton balls to simultaneously dab spots of water and rubbing alcohol onto the chalkboard. Have the class observe what happens to the spots. Ask students to infer which liquid has the greater vapor pressure at room temperature and explain their reasoning.

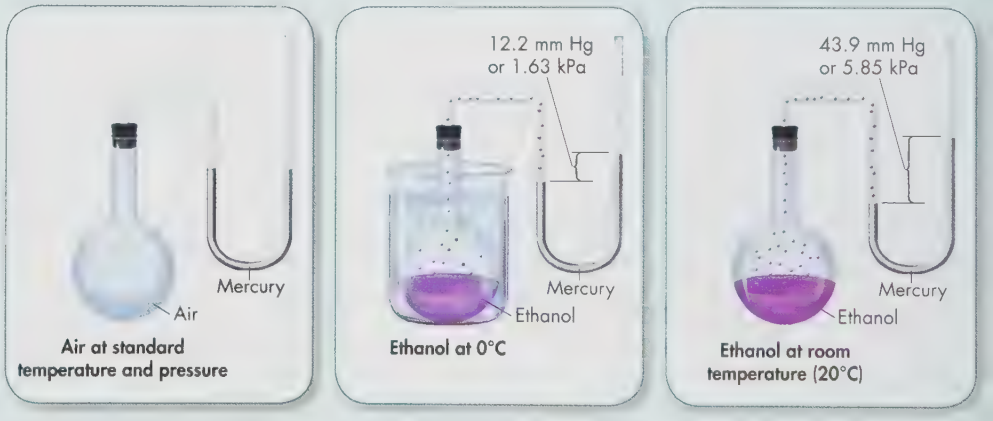
Explain

Boiling Point

APPLY CONCEPTS Explain that atmospheric pressure opposes the formation of bubbles in a liquid; bubbles form only when the vapor pressure inside a bubble is equal to atmospheric pressure.

Misconception Alert

Many students use the terms boiling and evaporation interchangeably. Explain that boiling is different from evaporation because evaporation can occur at any temperature, where as boiling occurs at specific temperatures and pressures.



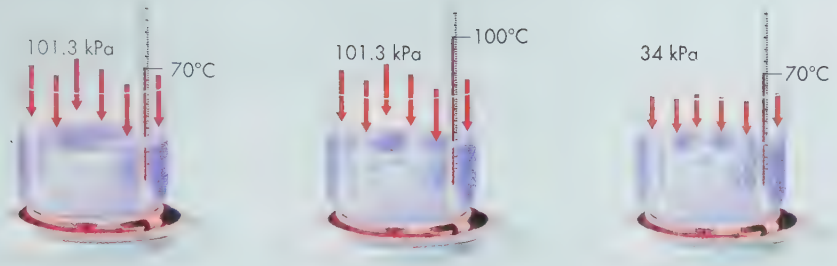
Vapor Pressure Measurements The vapor pressure of a liquid can be determined with a device called a manometer. Figure 13.7 shows how a simple manometer works. One end of a U-shaped glass tube containing mercury is attached to a closed container. The other end of the tube is open to the atmosphere. When there is only air in the container, the pressure is the same on both sides of the tube and the mercury level is the same in each arm of the tube. When a liquid is added to the container, the pressure in the container increases due to the vapor pressure of the liquid. The vapor pressure of the liquid pushes the mercury down on the container side of the U-tube. The levels of mercury in the U-tube are no longer the same. You can determine the vapor pressure in mm of Hg by measuring the difference between the two levels of mercury. As the vapor pressure increases, so does the difference between the two levels.

Boiling Point

Under what conditions does boiling occur?

The rate of evaporation of a liquid from an open container increases as the liquid is heated. Heating allows a greater number of particles at the liquid's surface to overcome the attractive forces that keep them in the liquid state. The remaining particles in the liquid move faster and faster as they absorb the added energy. Thus, the average kinetic energy of the particles in the liquid increases and the temperature of the liquid rises. **When a liquid is heated to a temperature at which particles throughout the liquid have enough kinetic energy to vaporize, the liquid begins to boil.** Bubbles of vapor form throughout the liquid, rise to the surface, and escape into the air. The **boiling point** (bp) is the temperature at which the vapor pressure of the liquid is just equal to the external pressure on the liquid.

Figure 13.7 Manometer
The vapor pressure of a contained liquid can be measured in a manometer. The vapor pressure is equal to the difference in height of the mercury in the two arms of the U-tube.
Calculate *What is the difference in vapor pressure between ethanol at 0°C and ethanol at 20°C?*



UbD

Check for Understanding

BIG IDEA **KINETIC THEORY** To assess students' understanding of the liquid processes explained in this lesson, have them write a short paragraph or create a two-column table, comparing and contrasting evaporation and boiling.

ADJUST INSTRUCTION If students struggle to explain the relationship between evaporation and boiling, have them reread the Evaporation and Boiling Point sections in the lesson. Then discuss various real-world examples to help students better connect to these concepts.

428 Chapter 13 • Lesson 2

Sea Level
Atmospheric pressure at the surface of water at 70°C is greater than its vapor pressure. Bubbles of vapor cannot form in the water, and it does not boil.

Sea Level
At the boiling point, the vapor pressure is equal to atmospheric pressure. Bubbles of vapor form in the water, and it boils.

Atop Mount Everest
At higher altitudes, the atmospheric pressure is lower than it is at sea level. Thus the water boils at a lower temperature.

Figure 13.8
Boiling Point and Altitude
A liquid boils when the vapor pressure of particles within the liquid equals the atmospheric pressure. The boiling point varies with altitude.

Boiling Point and Pressure Changes Because a liquid boils when its vapor pressure is equal to the external pressure, liquids don't always boil at the same temperature. Figure 13.8 shows how a change in altitude affects the boiling point of water. Because atmospheric pressure is lower at higher altitudes, boiling points decrease at higher altitudes. For example, in Denver, which is 1600 m above sea level, the average atmospheric pressure is 85.3 kPa. So water boils at about 95°C. In a pressure cooker, the vapor cannot escape and the vapor pressure increases. So water boils at a temperature above 100°C and food can cook more quickly.

Look at the vapor pressure versus temperature graph in Figure 13.9. You can use the graph to show how the boiling point of a liquid is related to vapor pressure. At a lower external pressure, the boiling point decreases. The particles in the liquid need less kinetic energy to escape from the liquid. At a higher external pressure, the boiling point increases. The particles in the liquid need more kinetic energy to escape from the liquid.

InterpretGraphs

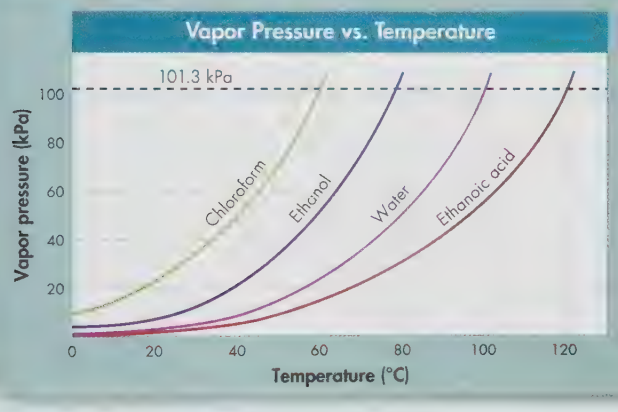


Figure 13.9 On the graph, the intersection of a curve with the 101.3-kPa line indicates the boiling point of that substance at standard pressure.
a. Read Graphs What is the boiling point of chloroform at 101.3 kPa?
b. Read Graphs What is the vapor pressure of ethanol at 40°C?
c. Predict What would atmospheric pressure need to be for ethanoic acid to boil at 80°C?

UbD Check for Understanding

What is the relationship between evaporation and kinetic energy?

Place a beaker of water over a flame or on a hot plate and let it come to a boil. Have students write a one-sentence answer to the following question.

Once the water begins to boil, why doesn't all of the water immediately evaporate? *(It takes a significant amount of kinetic energy to move a water molecule from the surface of the liquid to a vapor.)* Also, the more water there is in the pot, the longer it will take the water to evaporate.

ADJUST INSTRUCTION If students have difficulty answering the question, have them reread the text in the Evaporation section. Have students consider how the mass of the water affects the amount of kinetic energy it takes to evaporate the water.

Explore

Class Activity

PURPOSE To dispel the misconception that the temperature of a liquid increases as it boils

MATERIALS thermometer, beaker, ring stand, thermometer clamp, water, hot plate

SAFETY Students must wear Safety goggles, an apron, and mitts to protect them from the boiling water and steam. **CAUTION** *Steam can cause a more severe burn than boiling water can.*

PROCEDURE Have students measure the temperature every 30 seconds for several minutes as water is heated and then boiled. Have students use their data to construct a graph of temperature versus time. Ask students to write a short paragraph explaining their results.

MAKE A CONNECTION Discuss the effect of altitude on cooking time. **Ask** Why does it take longer to cook food in water at high altitudes? *(Because atmospheric pressure decreases with altitude, water boils at a lower temperature and the food doesn't cook as quickly.)* Why does food take less time to cook in a pressure cooker? *(In a pressure cooker the pressure can be greater than atmospheric pressure. Thus, the boiling point of water can be higher, and the food takes less time to cook.)*

Explain

USE VISUALS Direct students' attention to Figure 13.9. **Ask** Why doesn't the temperature/vapor pressure relationship show a straight line for the four substances shown? *(The relationship between temperature and vapor pressure is not linear because there is not a constant change in vapor pressure with a constant change in temperature.)*

Answers

FIGURE 13.7 4.22 kPa or 31.7 mm Hg

INTERPRET GRAPHS

a. 60°C
b. about 20 kPa
c. about 30 kPa

Evaluate

Informal Assessment

Ask students to summarize the general characteristics that distinguish a liquid from a gas. *(Gases can expand to fill their containers. Gases are easily compressed. Liquids conform to the shape of their containers, but do not expand to fill them. Liquids are not as easy to compress as gases because the spaces between particles in a liquid are much smaller than those in a gas.)*

Then direct students to complete the 13.2 Lesson Check.

Reteach

Illustrate for the students that the temperature at which the vapor pressure of a liquid is equal to the atmospheric pressure is the boiling point of the liquid. Depict that the exact temperature at which boiling occurs depends on the strength of the intermolecular attractions between molecules in the liquid and the magnitude of the atmospheric pressure. Point out that when the atmospheric pressure is reduced below the vapor pressure of water, water will boil at room temperature.

Figure 13.10 Boiling Water
You should be careful when working with boiling water as you could get a burn from either the water or the invisible water vapor, or steam, in the air just above the water.

Table 13.2
Normal Boiling Points of Several Substances

Substance	Boiling Point (°C)
Carbon disulfide (CS_2)	46.0
Chloroform ($CHCl_3$)	61.7
Methanol (CH_4O)	64.7
Carbon tetrachloride (CCl_4)	76.8
Ethanol (C_2H_6O)	78.5
Water (H_2O)	100.0

Boiling is a cooling process, similar to evaporation. During boiling, the particles with the highest kinetic energy escape first when the liquid is at the boiling point. Turning off the source of external heat drops the liquid's temperature below its boiling point. Supplying more heat allows more particles to acquire enough kinetic energy to escape. However, the temperature of the boiling liquid never rises above its boiling point. If heat is supplied at a greater rate, the liquid only boils faster. The vapor produced is at the same temperature as that of the boiling liquid. Although the vapor has the same average kinetic energy as the liquid, its potential (or stored energy) is much higher. Thus, a burn from steam is more severe than one from an equal mass of boiling water, even though they are both at the same temperature. This is one of the reasons why you need to be careful when straining boiling water from pasta or vegetables, as shown in Figure 13.10.

Normal Boiling Point A liquid can have various boiling points depending on pressure. The **normal boiling point** is defined as the boiling point of a liquid at a pressure of 101.3 kPa. Table 13.2 lists the normal boiling points of six molecular compounds.

13.2 LessonCheck

10. Identify What factors help determine the physical properties of liquids?

11. Explain In terms of kinetic energy, explain how a molecule in a liquid evaporates.

12. Describe A liquid is in a closed container and has a constant vapor pressure. What is the relationship between the rate of evaporation of the liquid and the rate of condensation of the vapor in the container?

13. Relate Cause and Effect What condition must exist for a liquid to boil?

14. Interpret Graphs Use Figure 13.9 to determine the boiling point of ethanoic acid at 27 kPa and chloroform at 80 kPa.

15. Explain Why does the boiling point of a liquid vary with atmospheric pressure?

16. Infer Explain how evaporation lowers the temperature of a liquid.

BIG IDEA KINETIC THEORY

17. Why does a liquid take the shape but not the volume of its container?

Lesson Check Answers

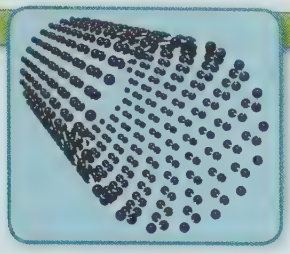
10. the interplay between the disruptive motions of particles in a liquid and the attractions among the particles

11. A molecule with a certain minimum kinetic energy can escape from the surface of the liquid and vaporize.

12. Rate of evaporation equals the rate of condensation.

13. Particles throughout the liquid must have enough kinetic energy to vaporize.

14. about 76°C; about 52°C



15. Boiling occurs when the vapor pressure of a liquid equals the external pressure. If the atmospheric pressure changes, the boiling point will change.

16. When the molecules with the highest kinetic energy escape from the liquid, the average kinetic energy of the remaining particles is lower and the temperature decreases.

17. BIG IDEA A liquid has a definite volume because of the attractive forces between the particles. A liquid conforms to the shape of its container because the kinetic energy of the particles allows them to move past one another.

13.3 The Nature of Solids

C.1.5 States of matter; C.3.3 Chemical bonds and intermolecular attractions; C.6.1 Explain that atoms and molecules are in constant motion

CHEMISTRY & YOU

Q: *What is the strongest material in the world?* It's not steel or any synthetic plastic, but a form of pure carbon known as fullerene nanotubes. These cylindrical structures, formed from carbon atoms linked together in hexagonal patterns, are over 300 times stronger than steel. They can be made with a diameter of only a few nanometers (hence the name) but several millimeters in length. Researchers in many different fields are finding new applications and possibilities for these structures, part of the new area of research known as nanotechnology. You will find out about fullerenes in this section.

Key Questions

- *How are the structure and properties of solids related?*
- *What determines the shape of a crystal?*

Vocabulary

- melting point
- freezing point
- crystal
- unit cell
- allotropes
- amorphous solid
- glass

A Model for Solids

How are the structure and properties of solids related?

The particles in liquids are relatively free to move. The particles in solids, however, are not. **The general properties of solids reflect the orderly arrangement of their particles and the fixed locations of their particles.** In most solids, the atoms, ions, or molecules are packed tightly together. These solids are dense and not easy to compress. Because the particles in solids tend to vibrate about fixed points, solids do not flow.

When you heat a solid, its particles vibrate more rapidly as their kinetic energy increases. The organization of particles within the solid breaks down, and eventually the solid melts. The **melting point** (mp) is the temperature at which a solid changes into a liquid. At this temperature, the disruptive vibrations of the particles are strong enough to overcome the attractions that hold them in fixed positions. The **freezing point** (fp) is the temperature at which a liquid changes into a solid. The melting and freezing points of a substance are at the same temperature. At that temperature, the liquid and solid phases are in equilibrium.

$$\text{Solid} \underset{\text{freezing}\leftarrow}{\overset{\text{melting}\rightarrow}{\rightleftharpoons}} \text{Liquid}$$

In general, ionic solids have high melting points because relatively strong forces hold them together. Sodium chloride, an ionic compound, has a rather high melting point of 801°C. By contrast, molecular solids have relatively low melting points. For example, hydrogen chloride, a molecular compound, melts at −112° C. Not all solids melt, however. Wood and cane sugar, for example, decompose when heated.

Focus on ELL

1 CONTENT AND LANGUAGE Read aloud each of the vocabulary words, and guide students to use prior knowledge to predict their meanings. Help students pronounce the words *allotrope* and *amorphous*.

2 FRONTLOAD THE LESSON Explain that this is the third state of matter students will study. Review the key questions and answers in Lessons 13.1 and 13.2. Then have students read the key questions for this lesson and predict the answers based on what they now understand about gases and liquids

3 COMPREHENSIBLE INPUT Briefly review what students learned about crystalline structure with respect to coordinate numbers in ionic crystals and atom arrangement in metallic crystals (see Lessons 7.2 and 7.3). Then preview Figures 13.11 through 13.13, pointing out the connections to the concepts from Chapter 7.

LESSON 13.3

Key Objectives

13.3.1 DESCRIBE how the structure and properties of solids related.

13.3.2 IDENTIFY the factors that determine the shape of a crystal.

Additional Resources

Reading and Study Workbook, Lesson 13.3

Available Online or on Digital Media:

Engage

CHEMISTRY & YOU Have students read the opening paragraph and examine the illustration. **Ask** What does the number of bonds and bond angles between carbons in fullerene suggest about its structure? *(Some of the carbons are connected by double bonds.)* Explain that the double bonds partially explain the strength of the nanotubes. Tell students that they will discover the rest of the explanation as they proceed with the lesson.

Activate Prior Knowledge

Assess students' knowledge of types of compounds by asking them to compare the structures of molecular and ionic compounds. *(Ionic compounds are composed of ions and are usually formed from a metal and a nonmetal. Molecular compounds are composed of molecules formed from two or more nonmetallic elements.)*

IN ACADEMIC STANDARDS for SCIENCE

C.1.5 Describe the characteristics of solids, liquids, and gases and state changes at the molecular level.

C.3.3 Compare and contrast ionic, covalent network, metallic and polar and non-polar molecular crystals with respect to constituent particles, strength of bonds, melting and boiling points, and conductivity; provide examples of each type.

C.6.1 Explain that atoms and molecules that make up matter are in constant motion and that this motion increases as thermal energy increases.

Foundations for Reading

BUILD VOCABULARY Explain that the word *amorphous* comes from the Greek prefix *a-*, meaning "not," and the Greek root *morph*, meaning "form." Have students use this information to predict the meaning of the term *amorphous*. Have students use a similar word strategy to help them learn the meaning of allotropes.

READING STRATEGY Have students make a table summarizing the characteristics of the seven crystal systems described in this section.

Explore

Crystal Structure and Unit Cells

PURPOSE Students will explore an analogy for the crystal lattices in solids.

MATERIALS samples of wallpaper with repeating patterns

PROCEDURE Explain that wallpaper patterns often consist of a small group of images that are repeated to obtain the overall effect. The group of images is like a unit cell in a crystal lattice. Ask students to identify the "unit cells" in wallpaper samples. Show students how to obtain a set of "lattice points" by choosing the same point in each unit of the repeating pattern. The collection of lattice points shows the fundamental arrangement of the units in the pattern. Ask students if they could arrange the components of each unit differently to produce a different "unit cell."

EXPECTED OUTCOME Students observe two-dimensional arrangements at the macroscopic level that are analogous to the three-dimensional arrangements in crystal lattices.

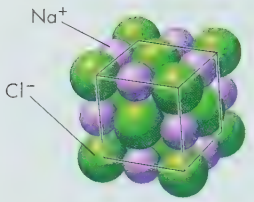

Figure 13.11 Ionic Crystal
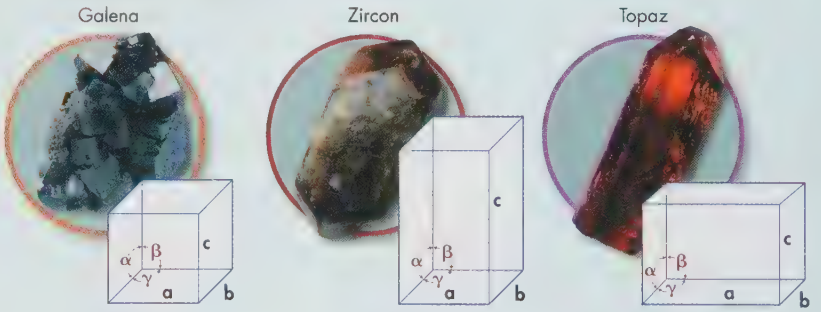
In sodium chloride (NaCl), sodium ions (Na^+) and chloride ions (Cl^-) are closely packed in a regular array. The ions vibrate about fixed points on the crystal.

Crystal Structure and Unit Cells



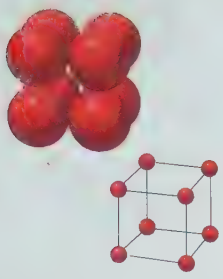
What determines the shape of a crystal?

Most solid substances are crystalline. In a **crystal,** the particles are arranged in an orderly, repeating, three-dimensional pattern called a crystal lattice. Figure 13.11 shows part of the crystal lattice in sodium chloride. **The shape of a crystal reflects the arrangement of the particles within the solid.**

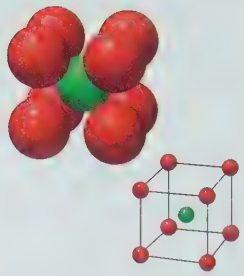
Crystal Systems A crystal has sides, or faces. The angles at which the faces of a crystal intersect are always the same for a given substance and are characteristic of that substance. Crystals are classified into seven groups, or crystal systems, which have the characteristic shapes shown in Figure 13.12. The edges are labeled a, b, and c. The angles are labeled α, β, and γ. The seven crystal systems differ in terms of the angles between the faces and in the number of edges of equal length on each face.

The shape of a crystal depends on the arrangement of the particles within it. The smallest group of particles within a crystal that retains the geometric shape of the crystal is known as a **unit cell.** A crystal lattice is a repeating array of any one of fourteen kinds of unit cells. Each crystal system can be composed of from one to four types of unit cells. Figure 13.13 shows the three kinds of unit cells that can make up a cubic crystal system.

Figure 13.12 Crystal Systems
Crystals are classified into seven crystal systems.
Classify *In which of the systems are all three angles equal to 90°?*

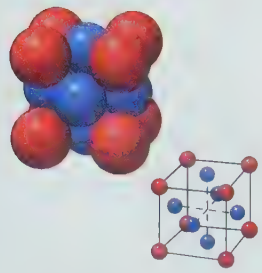


Differentiated Instruction



L3 ADVANCED STUDENTS Have students do research on the crystalline structure and formation of natural, synthetic, and simulated diamonds. Have students write a short paper comparing the three kinds of crystalline structures.

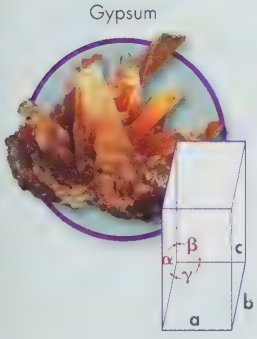
LPR LESS PROFICIENT READERS Have students create a concept map centered around the term *solid.* Their maps should highlight the relationship between solids and crystals and amorphous solids. Students should determine where unit cells, allotropes, and amorphous solids fit into their concept map.



ELL SPECIAL NEEDS STUDENTS Explain that morphing is a special effect used in films or videos to change the shape or form of an object. Have physically impaired students go online to find an example of morphing. Have them compare their example of morphing to an amorphous solid. Allow class time for them to share their findings.

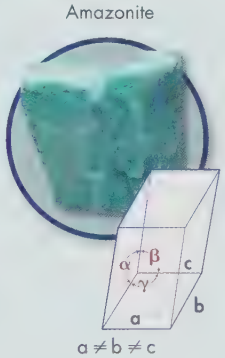
Simple Cubic In a simple cubic unit cell, the atoms or ions are arranged at the corners of an imaginary cube.

Body-Centered In a body-centered cubic unit cell, the atoms or ions are at the corners and in the center of an imaginary cube.



Face-Centered In a face-centered cubic unit cell, there are atoms or ions at the corners and in the center of each face of the imaginary cube.

Figure 13.13 Unit Cells The unit cell in a cubic crystal system may be simple cubic, body-centered cubic, or face-centered cubic. In the space-filling models and line drawings, the spheres represent atoms or ions.



Allotropes Some solid substances can exist in more than one form. A good example is the element carbon. Diamond is one crystalline form of carbon. It forms when carbon crystallizes under tremendous pressure (thousands of atmospheres). A different crystalline form of carbon is graphite. The lead in a pencil is not the element lead; it is graphite. In graphite, the carbon atoms are packed in sheets rather than in the extended three-dimensional array characteristic of diamond.

In 1985, a third crystalline form of carbon was discovered in ordinary soot. This form of carbon is called buckminsterfullerene. The carbon atoms in buckminsterfullerene are bonded together in groups of 60 atoms to form a hollow sphere, or cage, known as a buckyball. The atoms are arranged in a pattern of hexagons and pentagons on the surface of the cage, similar to the pattern on the surface of a soccer ball. Since 1985, other molecules of carbon with hollow cages have been discovered. The one with 70 carbon atoms is shaped like a football. As a group, these forms of carbon are called fullerenes.

Rhombohedral

Professional Development Note — Natural Glass

The most familiar examples of glass are made by man: plate glass, blown glass, and pressed glass. However, glass also forms naturally as the result of geologic and meteorologic processes. Volcanic glass is called obsidian, and forms when molten silicon dioxide (silica) cools so rapidly that mineral crystals of any significant size are unable to form. Because obsidian develops the characteristic razor-sharp edges associated with broken and chipped glass, it was highly prized by Stone Age toolmakers. Later civilizations used it for ceremonial weaponry and other ornaments.

Meteorological events that generate significantly high temperatures are also capable of forming glass. Lightning strikes in sandy areas form structures called *fulgurites*, which are essentially hollow glass tubes. Meteor impacts form rounded shapes called *tektites*.

Explore

Teacher Demo

MATERIALS dishwashing detergent, watch glass, overhead projector, drinking straw

PROCEDURE You can use an aqueous solution of detergent to make a model of a crystalline solid. Place the solution in a watch glass on an overhead projector and use a straw to blow bubbles into the solution. The bubbles form a regular, repeating pattern that is analogous to the arrangement of unit cells in a crystalline solid.

Explain

USE VISUALS Review basic geometric concepts of three-dimensional solids prior to introducing Figure 13.12. Explain that the properties of the crystals shown in the diagram are based on their geometric construction.

MAKING CONNECTIONS Have students describe how a higher degree of organization and stronger intermolecular attractions between particles distinguish solids from gases and liquids.

Answers

FIGURE 13.12 cubic, tetragonal, and orthorhombic

Explain

CRITICAL THINKING Ask students if to determine if any elements besides carbon exist in different allotropic forms. *(Elemental oxygen occurs as O_2 and O_3, both of which are gases; sulfur can exist as monoclinic or orthorhombic crystals; phosphorus can exist as red or white phosphorus, which are solids at room temperature.)*

CHEMISTRY & YOU As Figure 13.14 shows, the arrangement of the atoms give fullerene its hollowed-out shape. Its shape is the reason why fullerene is so strong.

Extend

Connect to TECHNOLOGY

Explain that scientists can manipulate the crystal structure of various materials to improve certain physical properties. Note that one such method is the production of alloys such as steel, as discussed in Lesson 7.4. Another method is the production of semi-conductors, which led to the development of many important advances in electronics. Have students research the history, structure and uses of key semi-conductors in today's electronics, and report their findings to the class.

Evaluate

Informal Assessment

Ask students to describe orally, or in paragraph form the distinguishing characteristics of crystalline solids and amorphous solids.

(Crystalline solids are characterized by an orderly, repeating three-dimensional arrangement of atoms, ions, or molecules. All crystals have a regular shape that reflects the arrangement of particles in the solid. Amorphous solids lack a well-defined arrangement of particles.)

Reteach

Describe how a higher degree of organization and stronger intermolecular attractions between particles distinguishes solids from gases and liquids. Have students consider how these factors are related to the ability of solids to retain their shape without a container.

Diamond In diamond, each carbon atom in the interior of the diamond is strongly bonded to four others. The array is rigid and compact.

Graphite In graphite, the carbon atoms are linked in widely spaced layers of hexagonal (six-sided) arrays.

Fullerene In buckminsterfullerene, 60 carbon atoms form a hollow sphere. The carbons are arranged in pentagons and hexagons.

Figure 13.14 Allotropes of Carbon Diamond, graphite, and fullerenes are allotropes of carbon.
Classify ***Based on the arrangements of their atoms, explain why the properties of fullerenes are closer to those of diamond than of graphite.***

The physical properties of diamond, graphite, and fullerenes are quite different. Diamond has a high density and is very hard. Graphite has a relatively low density and is soft and slippery. The hollow cages in fullerenes give them great strength and rigidity. Diamond, graphite, and fullerenes are crystalline allotropes of carbon. **Allotropes** are two or more different molecular forms of the same element in the same physical state. Although allotropes are composed of atoms of the same element, they have different properties because their structures are different. Figure 13.14 compares the structures of carbon allotropes. Only a few elements have allotropes. In addition to carbon, these include phosphorus, sulfur, oxygen (O_2 and O_3), boron, and antimony.

CHEMISTRY & YOU

Q: *What structural properties make fullerene nanotubes the strongest material in the world? Refer to Figure 13.14 in your answer.*

Non-Crystalline Solids Not all solids are crystalline in form; some solids are amorphous. An **amorphous solid** lacks an ordered internal structure. Rubber, plastic, and asphalt are amorphous solids. Their atoms are randomly arranged. Other examples of amorphous solids are glasses. A **glass** is a transparent fusion product of inorganic substances that have cooled to a rigid state without crystallizing. Glasses are sometimes called supercooled liquids. The irregular internal structures of glasses are intermediate between those of a crystalline solid and those of a free-flowing liquid. Glasses do not melt at a definite temperature. Instead, they gradually soften when heated. When a crystalline solid is shattered, the fragments have the same surface angles as the original solid. By contrast, when an amorphous solid, such as glass, is shattered, the fragments have irregular angles and jagged edges.

13.3 LessonCheck

18. **Describe** In general, how are the particles arranged in solids?

19. **Explain** What does the shape of a crystal tell you about the structure of a crystal?

20. **Compare** How do allotropes of an element differ?

21. **Identify** What phases are in equilibrium at a substance's melting point?

22. **Compare** How do the melting points of ionic solids generally compare with those of molecular solids?

23. **Explain** What is the difference between a crystal lattice and a unit cell?

BIG IDEA KINETIC THEORY

24. Why does a solid have a definite shape and a definite volume?

Lesson Check Answers

18. Particles in solids are packed tightly together in an orderly arrangement. The locations of the particles are fixed.

19. The shape of a crystal reflects the arrangement of the particles within the solid.

20. Allotropes are different molecular forms of the same element in the same physical state.

21. The liquid and solid states are in equilibrium.

22. Ionic solids generally have higher melting points than do molecular solids.

23. A crystal lattice is a repeating array of unit cells.

24. **BIG IDEA** The particles in a solid are packed tightly together and are not free to move. This arrangement of particles gives solids its definite shape and volume.

Small-Scale Lab

The Behavior of Liquids and Solids

Purpose

To explore and explain some behaviors of liquids and solids.

Materials

- plastic Petri dish
- water
- ice
- rubbing alcohol
- graph paper, 1-cm
- calcium chloride

Procedure

1. In your notebook, make a copy of the table shown below. Add a column for your observations. In the experiments, you will place substances labeled A and B inside the Petri dish and substances labeled C on top of the dish.

2. For Experiment 1, place one drop of water in the Petri dish. Replace the cover and place a small piece of ice on top of the cover.

3. After a few minutes, observe the interior surface of the Petri dish cover and the contents of the dish. Record your observations. Clean and dry the Petri dish and cover.

4. Repeat Steps 2 and 3 for Experiments 2–5, using the materials listed in the table. For Experiment 4, place the Petri dish on the graph paper so that you can place the water and the calcium chloride about 3 cm apart.

Experiment	Substance A	Substance B	Substance C
1	drop of water	–	ice cube
2	drop of water	–	drop of water
3	drop of rubbing alcohol	–	drop of water
4	drop of water	piece of $CaCl_2$	–
5	–	several pieces of $CaCl_2$	ice cube

Analyze and Conclude

Using your experimental data, record the answers to the following questions beneath your data table.

1. Draw Conclusions Explain your observations in Experiment 1 in terms of the behavior of liquids.

2. Explain Why is ice not needed for cloud formation in Experiment 2?

3. Compare What differences do you observe about the behavior of rubbing alcohol in Experiment 3 and the behavior of water in the previous experiments? Explain.

4. Predict What happens to solid calcium chloride in a humid environment?

5. Draw Conclusions Propose an explanation for no cloud formation in Experiment 5.

You're the Chemist

1. Analyze Data Place a drop of water and a drop of rubbing alcohol about 3 cm apart in a Petri dish. Cover the dish and place it on a piece of graph paper. Be careful not to mix the contents. Observe what happens to the size of the water drops over time.

2. Analyze Data Add a drop of bromothymol blue (BTB) to a drop of vinegar. What happens?

3. Design an Experiment Vinegar is a solution of water and ethanoic acid, $C_2H_4O_2$. Design and carry out an experiment to see if ethanoic acid will evaporate from a drop of vinegar. Does ethanoic acid evaporate?

4. Design an Experiment Design and carry out an experiment to see if ammonia will evaporate from a drop of aqueous ammonia.

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the lab. Make sure each group has ELLs of varied language proficiencies, so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Restate each step in simple terms. Demonstrate each step before students perform it.

INTERMEDIATE: LOW/HIGH Paraphrase the procedures before students begin. Allow them to answer the Analyze and Conclude questions with a partner.

ADVANCED: LOW/HIGH Discuss the procedures and the Analyze and Conclude questions before students begin. Discuss the meanings of words that may be unfamiliar, such as *formation* and *aqueous*.

Small-Scale Lab

OBJECTIVE After completing this activity, students will be able to explain some behaviors of liquids and solids.

SKILLS FOCUS Observing, inferring, drawing conclusions

PREP TIME 20 minutes

CLASS TIME 40 minutes

MATERIALS plastic Petri dish, water, ice, rubbing alcohol, calcium chloride, graph paper (1-cm), bromothymol blue solution (BTB), vinegar, aqueous ammonia

ADVANCE PREPARATION Purchase vinegar, aqueous ammonia, and rubbing alcohol. If you purchase BTB as a powder, prepare a 0.04% solution by dissolving 100 mg BTB powder in 16.0 mL 0.01*M* NaOH. Dilute to 250 mL.

SAFETY Be sure students wear goggles and aprons. BTB can stain clothing and skin. The room should be well ventilated and there should be no flames.

EXPECTED OUTCOMES The answers to the Analyze questions include a description of the expected outcome for each experiment.

ANALYZE AND CONCLUDE

1. Water in the dish evaporates and condenses into a cloud when it contacts the cold surface under the ice.
2. The drop of water on top of the dish provides enough cooling to cause cloud formation.
3. Water beads up and alcohol spreads because the intermolecular attractions in water are stronger.
4. Calcium chloride absorbs water from the environment in the dish.
5. The many pieces of calcium chloride effectively dry the atmosphere, leaving no water vapor in the dish.

YOU'RE THE CHEMIST

1. The water drop increases in diameter over time as the alcohol evaporates and is "captured" by the water drop. The attractions in the resulting mixture are weaker overall.
2. The BTB turns from green to yellow in the presence of vinegar.
3. Place a drop of vinegar and a drop of BTB about 3 cm apart in a Petri dish. Cover and observe. The BTB slowly changes from green to yellow. Ethanoic acid that evaporates is "captured" by the BTB.
4. Place a drop of ammonia and a drop of BTB about 3 cm apart in a Petri dish. Cover and observe. The BTB slowly changes from green to blue. Ammonia that evaporates is "captured" by the BTB.

Answers

FIGURE 13.14 The hollow cages have a structure that is closer to diamond's rigid structure than to the widely spaced layers in graphite.

LESSON 13.4

Key Objectives

13.4.1 IDENTIFY the conditions necessary for sublimation.

13.4.2 DETERMINE how the conditions at which phases are in equilibrium are represented on a phase diagram.

Additional Resources

Reading and Study Workbook, Lesson 13.4

Available Online or on Digital Media:

- Teaching Resources, Lesson 13.4 Review, Interpreting Graphics
- Laboratory Manual, Lab 22

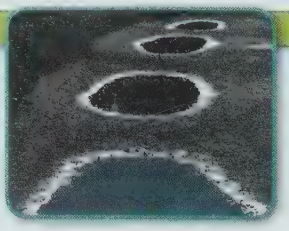
PearsonChem.com

Engage

CHEMISTRY & YOU Explain that rain is the condensation product of water vapor in the atmosphere. **Ask** Describe the water cycle in terms of phase changes. *(Answers will vary, but responses should focus on evaporation, condensation, and precipitation.)* Use the discussion to introduce sublimation.

Activate Prior Knowledge

Display in the room a large poster of the water cycle. Use colored sticky notes to represent solids, liquids, and gases. Have student volunteers place the sticky notes in the correct location on the water cycle poster. Then discuss the relationship between temperature and the three phases of water as an introduction to the concepts addressed in Figure 13.18.



IN ACADEMIC STANDARDS for SCIENCE

- Develop explanations based on reproducible data and observations gathered during laboratory investigations.

C.1.5 Describe the characteristics of solids, liquids, and gases and state changes at the molecular level.

13.4 Changes of State

IN C.1.5 States of matter

CHEMISTRY & YOU

Q: *Where does rain water go when a puddle dries up?* Water cycles through much of the matter on Earth. It falls as liquid rain or solid snow, collects in rivers, oceans, or glaciers and returns to the air as a gas through evaporation. All living organisms use water and release it back into the air. Other elements, such as carbon and nitrogen, also cycle through Earth as solids, liquids, or gases. In this section, you will learn what conditions can control the state of a substance.

Key Questions

When can sublimation occur?

How are the conditions at which phases are in equilibrium represented on a phase diagram?

Vocabulary

- sublimation
- phase diagram
- triple point

Sublimation

When can sublimation occur?

If you hang wet laundry on a clothesline on a very cold day, the water in the clothes quickly freezes to ice. Eventually, however, if the day is sunny, the clothes become dry although the ice never thaws. The ice changes directly to water vapor without melting and passing through the liquid state. The change of a substance from a solid to a vapor without passing through the liquid state is called **sublimation.** Sublimation can occur because solids, like liquids, have a vapor pressure. **Sublimation occurs in solids with vapor pressures that exceed atmospheric pressure at or near room temperature.**

$$\text{Solid} \underset{\text{deposition}}{\overset{\text{sublimation}}{\rightleftharpoons}} \text{Vapor}$$

Iodine is another example of a substance that undergoes sublimation. This violet-black solid ordinarily changes into a purple vapor without passing through a liquid state. Notice in Figure 13.15 how dark crystals of iodine deposit on the outside of a test tube placed inside another test tube. The outer test tube contains solid iodine that is being gently heated. The inner test tube contains liquid water and ice. The iodine crystals at the bottom of the outer test tube change directly to iodine vapor. When the vapor reaches the cool surface of the inner test tube, it goes directly from the gaseous to the solid state.

Figure 13.15 Sublimation
When solid iodine is heated, the crystals sublime, going directly from the solid to the gaseous state. When the vapor cools, it goes directly from the gaseous to the solid state.

Focus on ELL

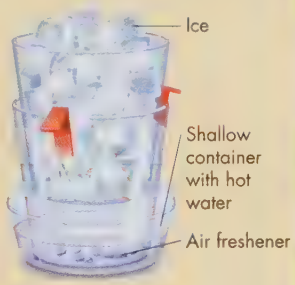
1 CONTENT AND LANGUAGE Students who know that the prefix *sub-* means "below or under" may be confused by the definition of sublimation. Explain that this word comes from the latin word *sublimare* which mean "to raise or elevate."

2 FRONTLOAD THE LESSON Ask students to predict whether a solid can change to a gas without first becoming a liquid. *(Answers will vary.)* Then, display a piece of dry ice in a beaker placed in a well-ventilated area, and have students examine the beaker for the presence of liquid (CAUTION: do not handle dry ice without appropriate Safety precautions and gear, as it can cause serious skin damage on contact.). Students should notice that there is no liquid in the beaker, and that the vapor appears to come directly from the solid CO_2. Explain that this type of phase change is not limited to dry ice, and that they will explore why such a phase change is possible.

Sublimation has many useful applications. If freshly brewed coffee is frozen and the water vapor is removed with a vacuum pump (a sublimation process), the result is freeze-dried coffee. The solid carbon dioxide (dry ice) shown in Figure 13.16 is often used as a coolant for goods, such as ice cream, that must remain frozen during shipment. Dry ice has a low temperature of −78°C. Because it sublimes, it does not produce a liquid, as ordinary ice does when it melts. Solid air fresheners contain a variety of substances that sublime at room temperature. Sublimation is also useful for separating substances. Organic chemists use sublimation to separate mixtures and to purify compounds.

Figure 13.16 Dry Ice Solid carbon dioxide, or dry ice, sublimes at normal atmospheric pressures. As it changes state, dry ice absorbs heat, keeping materials nearby cool and dry.
Interpret Photos *Why does fog form in the air around the dry ice?*

Quick Lab



Sublimation

Purpose
To observe the sublimation of air freshener

Materials
- small pieces of solid air freshener
- small shallow container
- 2 clear 8-oz plastic cups
- hot tap water
- ice
- 3 thick cardboard strips

Procedure

1. Place a few pieces of air freshener in one of the cups. **CAUTION** *Work in a well-ventilated room.*
2. Bend the cardboard strips and place them over the rim of the cup that has the air freshener pieces.
3. Place the second cup inside the first. The base of the second cup should not touch the air freshener. Adjust the cardboard as necessary. This assembly is your sublimator.
4. Fill the top cup with ice. Do not get any ice or water in the bottom cup.
5. Fill the shallow container about one-third full with hot tap water.

6. Carefully place your sublimator in the hot water. Observe what happens.

Analyze and Conclude
1. Define What is sublimation?
2. Predict What do you think would happen if the water in the shallow container were at room temperature? If it were boiling?
3. Explain Why is it possible to separate the substances in some mixtures by sublimation?

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the lab. Make sure each group has ELLs of varied language proficiencies, so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Rephrase each Procedure step in simple terms. Have students follow along as you demonstrate each step.

INTERMEDIATE: LOW/HIGH Slowly read each Procedure step aloud. Answer the Analyze and Conclude questions as a class. Have students copy the answers.

ADVANCED: LOW/HIGH Have more capable students help others with a lower language proficiency by posing the Analyze and Conclude questions as true/false questions.

Foundations for Reading

BUILD VOCABULARY Explain that the word *sublimation* comes from the Latin word *sublimare*, meaning "to elevate." Convey that the meaning of *sublimare* was expanded by the Middle Ages to include "to refine" or purify. The process of sublimation can be used to remove impurities from a substance.

READING STRATEGY Have students note key points about sublimation and evaporation as they read this lesson. Then ask them to summarize their key points in a paragraph comparing the two processes.

Explore

Sublimation

Quick Lab

OBJECTIVE After completing this activity, students will be able to describe the process of sublimation.

SKILLS FOCUS Observing, inferring, predicting, communicating

PREP TIME 15 minutes

CLASS TIME 20 minutes

SAFETY Perform this activity in a well-ventilated room. Some people are allergic to substances in air fresheners.

TEACHING TIPS Students should not fill the shallow containers to the point where the sublimator floats, to prevent it from tipping over. If a colored air freshener is used, the condensed solid will be white.

EXPECTED OUTCOME The heat from the hot water causes the air freshener to sublime. When the vapor reaches the cold surface of the upper cup, it condenses back into a solid.

ANALYZE AND CONCLUDE

1. The change of a substance from a solid to a gas without passing through the liquid state.
2. At room temperature, there would be less sublimation; at the boiling point, there would be more sublimation.
3. When a substance sublimes in a mixture, other components remain as residue.

FOR ENRICHMENT

If you used a colored air freshener, ask students to explain why the condensed solid is white. *(The dye does not sublime and remains behind at the bottom of the sublimator.)*

Explain

Phase Diagrams

USE VISUALS Draw the phase diagram of water in Figure 13.18 on the board. Have volunteers label the states of matter. Using simple words, ask students to demonstrate melting, and have a volunteer draw an arrow on the diagram from the solid to the liquid area. Repeat this for other changes of state.

Explain

USE VISUALS Display Figure 13.18 on an overhead projector. Explain that a phase diagram is a convenient way to summarize the conditions of temperature and pressure at which the solid, liquid, and gas phases of a substance are most stable. Point out that each line in the diagram represents the set of possible temperature-pressure values at which different phases are in dynamic equilibrium with one another. For example, in a closed system at 100°C and 101.3 kPa, liquid water is in dynamic equilibrium with water vapor. (Note that the *x*- and *y*-axes are not drawn to scale so that the triple point and normal boiling point can fit on the graph.) **Ask** At what temperature and pressure are the liquid, solid, and vapor phases of water in dynamic equilibrium? *(0.016°C, 0.61 kPa)*

Extend

By this point in the course students should have a strong understanding that reactions can occur between different states of matter as well as between liquids and between gases. However, they may not realize that reactions can also occur between solids. Explain to students that these types of reactions produce a number of useful products, including semi-conductors and light-sensitive photopolymers. A number of chemists specialize in solid-state chemistry. Have students research current areas of experimentation in solid state chemistry either on the Internet or by interviewing a solid-state chemist at a local college or university, and prepare a poster showing examples of applications of this research that are found in everyday objects.

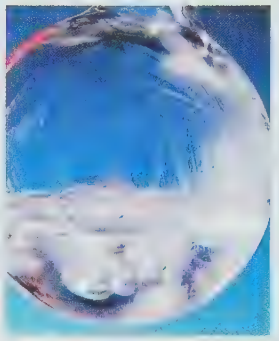


Figure 13.17 Triple point
This flask is at the triple point, where ice, liquid water, and water vapor exist in equilibrium. Freezing, melting, boiling, and condensation are all occuring at the same time in the flask.

Phase Diagrams

How are the conditions at which phases are in equilibrium represented on a phase diagram?

The relationships among the solid, liquid, and vapor states (or phases) of a substance in a sealed container can be represented in a single graph. The graph is called a **phase diagram.** A phase diagram gives the conditions of temperature and pressure at which a substance exists as solid, liquid, or gas (vapor). **The conditions of pressure and temperature at which two phases exist in equilibrium are indicated on a phase diagram by a line separating the phases.**

Figure 13.18 shows the phase diagram for water. In each of the colored regions of the phase diagram, water is in a single phase. The curving line that separates water's vapor phase from its liquid phase describes the equilibrium conditions for liquid and vapor. Under these conditions, water can change its state from liquid to vapor or from vapor to liquid. The same line also illustrates how the vapor pressure of water varies with temperature. The other two lines describe the conditions for equilibrium between liquid water and ice and between water vapor and ice. The point on the diagram at which all three lines meet is called the triple point. The **triple point** describes the only set of conditions at which all three phases can exist in equilibrium with one another. For water, the triple point is a temperature of 0.016°C and a pressure of 0.61 kPa (0.0060 atm). Figure 13.17 shows water at its triple point.

InterpretGraphs

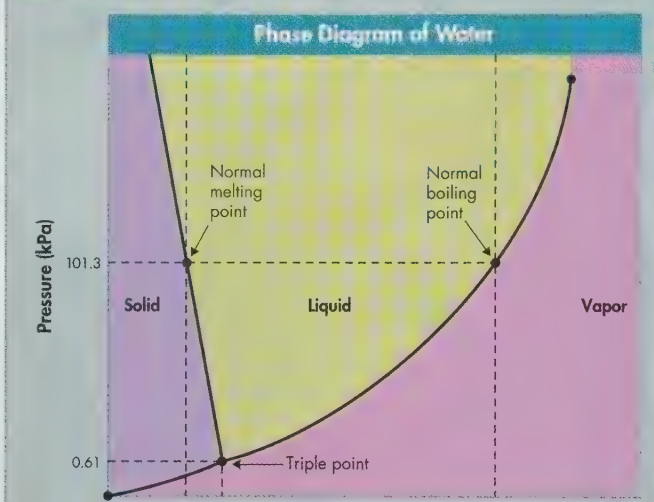

Figure 13.18 The phase diagram of water shows the relationship among pressure, temperature, and the physical states of water. Note that the scale on the axes is not linear.

a. Read Graphs At the triple point of water, what are the values of temperature and pressure?

b. Identify What states of matter are present at the triple point of water?

c. Analyze Assuming standard pressure, at what temperature is there an equilibrium between water vapor and liquid water? Between liquid water and ice?

Hint: Each line represents the set of possible temperature-pressure values at which the different phases are in dynamic equilibrium.

See boiling and freezing *animated online.*

Professional Development Note

Freeze-Dried Foods

Astronauts and backpackers use freeze-dried foods because they are lightweight and easily reconstituted by adding water. Freeze-dried foods don't require refrigeration because bacteria cannot multiply in the absence of moisture. The sublimation of ice at low pressure makes the process of freeze-drying possible. Food is frozen and placed in a chamber attached to a vacuum pump. Then the pressure in the chamber is lowered until the ice crystals sublime. Freeze-dried food tends to maintain its flavor because the substances in the food that impart flavor remain in the food as the ice sublimes.

By referring to Figure 13.18, you can determine what happens if you melt ice or boil water at pressures less than 101.3 kPa. A decrease in pressure lowers the boiling point and raises the melting point. An increase in pressure will raise the boiling point and lower the melting point.

Look at Figure 13.18. Follow the equilibrium line between liquid water and water vapor to the triple point. Below the triple point, the vapor and liquid cannot exist in equilibrium. Increasing the pressure won't change the vapor to a liquid. The solid and the vapor are in equilibrium at temperatures below 0.016°C. With an increase in pressure, the vapor begins to behave more like a solid. For example, it is no longer easily compressed.

Figure 13.18 also illustrates how an increase in pressure affects the melting point of ice. For years, the accepted hypothesis for how ice skaters move along the ice was the following. The blades of the skates exert pressure, which lowers the melting point of the ice. The ice melts and a film of water forms under the blades of the skates. This film acts as a lubricant, enabling the skaters to glide gracefully over the ice as shown in Figure 13.19. This hypothesis fails to explain why skiers also glide along very nicely on another solid form of water—snow. Wide skis exert much less pressure per unit area of snow than narrow skate blades exert on ice. Recent research shows that the surface of ice has a slippery, water-like surface layer that exists well below ice's melting point. Even ice that is at −129°C has this layer. A new hypothesis proposes that the liquid-like surface layer provides the lubrication needed for smooth skating and skiing.

CHEMISTRY & YOU

Q: *Describe how water might move from Earth's surface to Earth's atmosphere and back again as part of the water cycle. Be sure to include any phase changes that occur in your description.*

Figure 13.19 Water on Ice
The surface of ice has a thin layer of water above it.
Apply Concepts *Research shows that the colder the ice is, the thinner the layer of water above the ice is. In which sports—ice hockey, speed skating or figure skating—do you think that it would benefit the athletes more to keep the ice colder?*

13.4 LessonCheck

25. **Identify** What properties must a solid have to undergo sublimation?

26. **Explain** What do the curved lines on a phase diagram represent?

27. **Apply Concepts** Describe one practical use of sublimation.

28. **Interpret Graphs** Using Figure 13.18, estimate the boiling point of water at a pressure of 50 kPa.

29. **Explain** What does the triple point on a phase diagram describe?

30. **Classify** Would you expect a substance that sublimates at or near room temperature to be a molecular substance or an ionic substance? Use what you learned about bonding in Chapters 7 and 8 to answer the question.

CHEMISTRY & YOU The water in a pond evaporates. The water vapor in the atmosphere condenses to form clouds. When the water droplets in clouds get heavy enough, they fall to the ground as rain.

Evaluate

Informal Assessment

List a series of temperature–pressure values on the board. Have students state or point to which phase of water is most stable under each set of conditions and explain why.

Reteach

On the board, draw a stoppered, sidearm flask containing water and a chunk of ice. Note that the sidearm is connected to a vacuum pump. Tell students that the diagram illustrates ice, liquid water, and water vapor in equilibrium. Have groups of students approach the diagram and one at a time have a student add an arrow and label to the diagram to represent a phase change. Continue until there are six arrows on the diagram.

Lesson Check Answers

25. Sublimation occurs in solids that have vapor pressures that exceed atmospheric pressure at or near room temperature.

26. The lines show the conditions of temperature and pressure at which two phases exist in equilibrium.

27. freeze-dried coffee, dry ice as a coolant, air fresheners, separating mixtures, and purifying substances

28. about 60°C

29. The triple point describes the only set of conditions at which three phases can exist in equilibrium.

30. The substance is likely molecular because the bonds between ions are typically stronger than the attractions between molecules.

Answers

INTERPRET GRAPHS

a. 0.016°C and 0.61 kPa
b. solid, liquid, and vapor
c. 100°C; 0°C

FIGURE 13.19 A thick layer of water means that there is more friction, which can slow the skaters down. In ice hockey and speed skating, where speed is crucial, it is better to skate on colder ice. Also, the warmer the ice is the softer the surface of the ice is. In figure skating, the layer of water provides a cushion for the skaters if they fall.

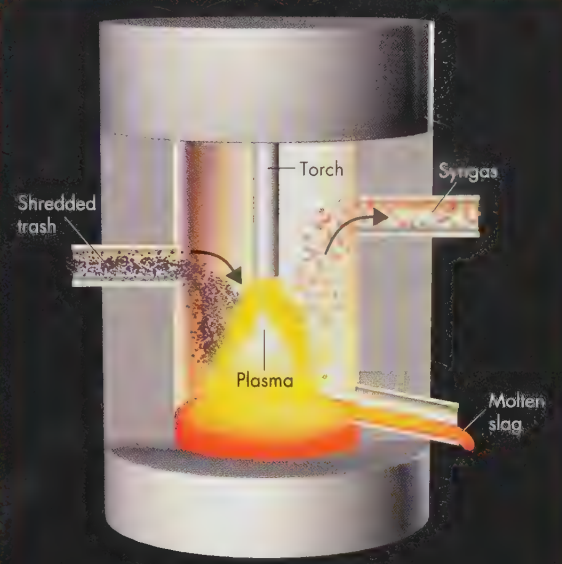
CHEMISTRY & YOU Hazardous wastes such as chemicals and medical items (biological fluids and tissues, syringe needles, and so on) are often buried in landfills or incinerated in traditional high-temperature incinerators. Both methods are effective, but have some serious disadvantages. For example, landfills rely on bacterial decomposition to destroy hazards. However, this requires time, and some chemicals do not undergo biological decomposition. Landfills also can leak, contaminating groundwater. High-temperature incinerators rely on combustion to destroy hazardous wastes, but must consistently reach temperatures greater than 1200°C to break chemical bonds. At lower temperatures, incomplete combustion or the formation of hazardous by-products may occur. Incomplete combustion results in soot formation. It may also take several hours for solid wastes to be completely incinerated.

Pose the following question to students: *Based on the description given in the feature, what are some benefits of using a plasma waste converter instead of burning waste material?*

You may need to guide students in the following ways:

- The temperature in a plasma furnace can be hotter than the surface of the Sun, which is 5497°C.
- Plasma furnaces are enclosed, unlike incinerators where waste is burned.
- Some high-temperature incinerators produce liquid waste that must be treated before it can be discharged into the sewer system.

Explain



START A CONVERSATION Engage students in discussing how a plasma is different from other states of matter. They should understand that, unlike other states of matter, a plasma is not made of neutral atoms. The particles of a plasma have so much energy that the electrons are stripped away, leaving positively charged ions and negatively charged electrons. Point out that, although other states of matter are more common on Earth, plasma is the most common state of matter in the universe. Stars, including our Sun, are made of plasma.

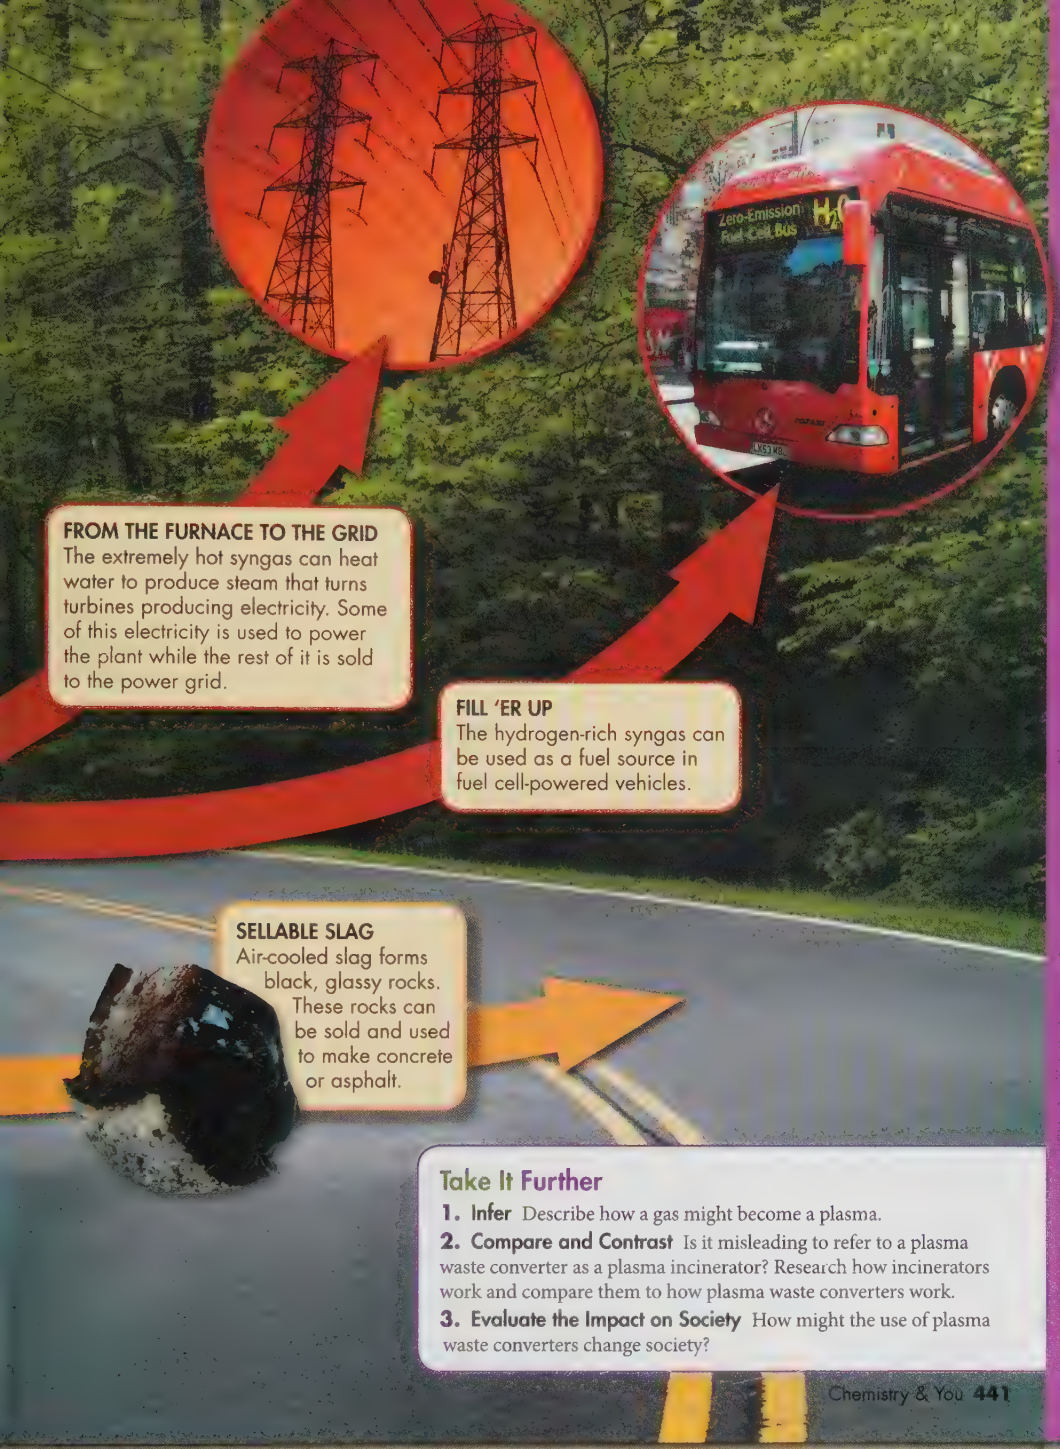
Plasma Waste Converter

You are very familiar with solids, liquids, and gases, but did you know that there's a fourth state of matter called plasma? A plasma is a gaseous mixture of freely moving positive ions and electrons. Plasmas exist naturally in the sun and other stars, and in lightning. Plasmas can also be artificially created and used in a variety of technologies. One new application of plasma technology is plasma waste converters, which treat most waste material, including many hazardous wastes.

Plasma waste converters produce plasmas with temperatures as high as 7,000°C. The energy within the plasma breaks the waste material's molecular bonds so that the material separates into its elemental components. The end products are a hydrogen-rich gas known as syngas and a solid known as slag.

Plasma waste converters have many benefits over traditional waste treatments. They do not require the use of dumps or landfills, and they emit much less greenhouse gases and other pollutants than incinerators. Despite these benefits there are currently only two plasma waste treatment plants that process municipal solid waste. This is mostly due to the cost since each plant must be custom-built. Standardizing production should result in the construction of more plants.

PLASMA FURNACE The plasma torches turn trash into syngas and slag. The composition of the trash determines the end products. Organic, or carbon-based matter, results in syngas while inorganic matter results in slag. The furnace is airtight, so that none of the syngas can escape.



SYNGAS
The gases pass from the furnace into a chamber where any remaining organic matter or hazardous wastes are removed. The gases can then be used as a fuel source or to make electricity.

SLAG
Any hazardous materials in the molten slag are inert and will not dissolve out of the slag. The slag takes different forms depending on how it is cooled.

21st Century Learning To be successful in the 21st century, students need skills and learning experiences that extend beyond subject matter mastery. The following project helps students build the following 21st Century Skills: *Creativity and Innovation; Communication and Collaboration; Information Literacy; Initiative and Self-Direction.*

USING PLASMA Pose the following challenge to your students. *Suppose you are the Safety supervisor for a welding company. It is your responsibility to train new welders about workplace Safety in regards to plasma welding equipment. Create a multimedia presentation on workplace Safety with regards to handling and using plasma welding equipment that includes a 15-20 minute computerized slide show and a take-home brochure.*

The presentation and brochure should explain the chemical and physical properties of plasma, why plasma it is used for welding, its advantages and disadvantages compared to other types of welding, and include all Safety considerations.

FROM THE FURNACE TO THE GRID
The extremely hot syngas can heat water to produce steam that turns turbines producing electricity. Some of this electricity is used to power the plant while the rest of it is sold to the power grid.

FILL 'ER UP
The hydrogen-rich syngas can be used as a fuel source in fuel cell-powered vehicles.

SELLABLE SLAG
Air-cooled slag forms black, glassy rocks. These rocks can be sold and used to make concrete or asphalt.

Take It Further

1. **Infer** Describe how a gas might become a plasma.
2. **Compare and Contrast** Is it misleading to refer to a plasma waste converter as a plasma incinerator? Research how incinerators work and compare them to how plasma waste converters work.
3. **Evaluate the Impact on Society** How might the use of plasma waste converters change society?

Differentiated Instruction

L1 STRUGGLING STUDENTS Have students study the feature with a partner. Instruct students to read each paragraph and discuss it before going to the next paragraph. Check with pairs frequently to provide guidance and answer questions.

ELL ENGLISH LANGUAGE LEARNERS List idiomatic and unfamiliar words in the feature on the board. For example, you might list *municipal, the grid, sellable, molten, fill 'er up, concrete,* and *asphalt.* Discuss their meanings before students attempt to read the feature.

L3 ADVANCED STUDENTS Have students research a municipal plasma waste conversion facility that exists today, or one that is being planned or built. Instruct students to provide a short summary for the class about the facility.

USE VISUALS Have students study the diagram of a plasma furnace and think about its different parts. **Ask** Why do you think the trash is shredded? *(to make breaking it down easier)* **Ask** How is the syngas (synthetic gas, pronounced sin gas) separated from the slag? *(The less-dense gas moves upward, and the denser slag flows out.)* **Ask** Why do you think the slag in the photo forms a glass rather than crystals? *(Like volcanic rocks, the slag cools so quickly that the particles do not have time to arrange themselves into a repeating pattern before the slag hardens.)*

Extend

Connect to ECONOMICS

Encourage students to consider whether a plasma waste converter ultimately has a higher or lower cost for society. Point out that although a plasma waste converter is expensive to build, the costs of not building it might be high also. For example, have students consider the costs to society of dealing with polluted air and storing toxic wastes such as PCBs.

Answers

TAKE IT FURTHER

1. Heat a gas until electrons begin to strip off the atoms.
2. Yes, it is misleading to refer to a plasma waste converter as a plasma incinerator because a plasma waste converter does not burn waste. Rather it breaks the waste down into its elemental components. Furthermore, a byproduct of incineration is ash. Ash must still be disposed of in landfills.
3. Less green space would have to be set aside for landfills. There may not be the need to recycle. Also, plasma waster converters could reduce society's dependence on fossil fuels.

STUDY GUIDE

Evaluate

Review and Assessment Materials

PROBLEM SETS Have students practice more kinetic theory problems by using the Chapter 13 Online Problem Set.

MATH SKILLS REVIEW Have struggling students practice solving algebraic equations by using the MathXL learning module.

VIRTUAL LABS Have students complete a virtual lab as an in-class or take-home assignment to help reinforce the relationships between temperature, pressure, and state of matter.

Study Tip

One excellent way to evaluate your knowledge of a key concept is to try to explain the concept to another person. The questions the other person asks will help you assess the depth of your knowledge.

UbD

Understanding by Design

Performance Tasks

COMIC STRIP Have students create and illustrate a comic strip that explains kinetic theory as it relates to different states of matter. Students may opt to generate their strips using an online comic strip creator or computer art software. The strips should utilize a storyline involving characters and a situation that demonstrates students' ability to successfully apply the kinetic theory to one or more substances.

TEACH A LESSON Divide the class into groups of four students. Assign each student within the group a topic: solid, liquid, gas, or change of state. Instruct students to prepare and teach their topic to others in their group. Encourage students to use multi-media or tactile examples as part of their instruction.

13 Study Guide

BIG IDEA KINETIC THEORY

The state of a substance is determined by conditions of pressure and temperature. Low pressures and high temperatures favor gases, in which particles move randomly in constant, high-speed motion. At higher pressures and lower temperatures, the particles slow down and exert attractive forces on one another, producing a liquid. At still higher pressures and lower temperatures, the particles become fixed in orderly arrangements, producing solids. A substance changes state when there is a change in the balance between the random motion of its particles and the attractions among those particles.

13.1 The Nature of Gases

- Particles in a gas are considered to be small, hard spheres with an insignificant volume. The motion of the particles in a gas is rapid, constant, and random. All collisions between particles in a gas are perfectly elastic.
- Gas pressure is the result of billions of rapidly moving particles in a gas simultaneously colliding with an object.
- The Kelvin temperature of a substance is directly proportional to the average kinetic energy of the particles of the substance.

- kinetic energy (420)
- kinetic theory (420)
- gas pressure (421)
- vacuum (421)
- atmospheric pressure (421)
- barometer (421)
- pascal (Pa) (422)
- standard atmosphere (atm) (422)

13.2 The Nature of Liquids

- The interplay between the disruptive motions of particles in a liquid and the attractions among the particles determines the physical properties of liquids.
- During evaporation, only those molecules with a certain minimum kinetic energy can escape from the surface of the liquid.
- In a system at constant vapor pressure, a dynamic equilibrium exists between the vapor and the liquid. The rates of evaporation and condensation are equal.
- At a temperature at which particles throughout a liquid have enough kinetic energy to vaporize, the liquid begins to boil.

- vaporization (426)
- evaporation (426)
- vapor pressure (427)
- boiling point (428)
- normal boiling point (430)

13.3 The Nature of Solids

- The general properties of solids reflect the orderly arrangement and the fixed locations of their particles.
- The shape of a crystal reflects the arrangement of the particles within the solid.

- melting point (431)
- freezing point (431)
- crystal (432)
- unit cell (432)
- allotropes (434)
- amorphous solid (434)
- glass (434)

13.4 Changes of State

- Sublimation occurs in solids with vapor pressures that exceed atmospheric pressure at or near room temperature.
- The conditions of pressure and temperature at which two phases exist in equilibrium are indicated on a phase diagram by a line separating the two regions representing the phases.

- sublimation (436)
- phase diagram (438)
- triple point (438)

Focus on ELL

5 ASSESS UNDERSTANDING Use the phase diagram in Figure 13.18 as an alternative oral assessment tool.

BEGINNING: LOW/HIGH Point to the *solid, liquid,* and *gas* areas. Have students use simple phrases to explain two properties of each state of matter.

INTERMEDIATE: LOW/HIGH Ask simple questions about the diagram, such as *What is sublimation?* Allow students to answer orally, using the diagram as a visual aid during their response.

ADVANCED: LOW/HIGH Have students use complete sentences to describe the different states of matter and explain changes of state using the diagram.

13 Assessment

* Solutions appear in Appendix E

Lesson by Lesson

13.1 The Nature of Gases

*31. What is meant by an elastic collision?

32. Which of these statements are characteristic of matter in the gaseous state?
   a. Gases fill their containers completely.
   b. Gases exert pressure.
   c. Gases have mass.
   d. The pressure of a gas is independent of the temperature.
   e. Gases are compressible.

33. List the various units used to measure pressure, and identify the SI unit.

34. Change 1656 kPa to atm.

*35. Change 190 mm Hg to kPa and atm.

36. Explain the relationship between the Kelvin temperature of a substance and the kinetic energy of its particles.

37. How is the average kinetic energy of water molecules affected when you pour hot water into cups at the same temperature as the water?

38. What does the abbreviation STP represent?

39. What is significant about the temperature absolute zero?

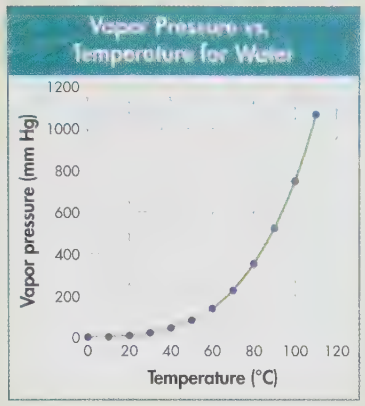
*40. By what factor does the average kinetic energy of the molecules of gas in an aerosol container increase when the temperature is raised from 27°C (300 K) to 627°C (900 K)?

13.2 The Nature of Liquids

41. Explain why liquids and gases differ in density and the ability to be compressed.

42. Compare evaporation of a liquid in a closed container with that of liquid in an open container.

*43. Describe what is happening at the molecular level when a dynamic equilibrium occurs.



44. Explain why increasing the temperature of a liquid increases its rate of evaporation.

45. Would you expect a dynamic equilibrium in a liquid in an open container? Explain.

46. Describe the effect that increasing temperature has on the vapor pressure of a liquid.

47. Distinguish between the boiling point and the normal boiling point of a liquid.

48. Use the graph to answer each question.

   a. What is the vapor pressure of water at 40°C?
   b. At what temperature is the vapor pressure of water 600 mm Hg?
   c. What is the significance of the vapor pressure of water at 100°C?

*49. Explain how boiling is a cooling process.

13.3 The Nature of Solids

50. Name at least one physical property that would permit you to distinguish a molecular solid from an ionic solid.

51. Describe what happens when a solid is heated to its melting point.

*52. Explain why molecular solids usually have lower melting points than ionic solids.

13.4 Changes of State

*53. When you remove the lid from a food container that has been left in a freezer for several months, you discover a large collection of ice crystals on the underside of the lid. Explain what has happened.

54. Explain why a liquid stays at a constant temperature while it is boiling.

LESSON 13.4

53. Water from the food sublimed and then condensed on the lid.

54. The temperature remains constant while the liquid boils because the energy that is added is used to vaporize the molecules.

Evaluate

Answers

LESSON 13.1

31. In an elastic collision, energy is transferred between particles.

32. a, b, c, and e

33. pascal (Pa), SI; millimeter of mercury (mm Hg); atmosphere (atm)

34. 16.35 atm

35. 25 kPa and 0.25 atm

36. The Kelvin temperature is directly proportional to the average kinetic energy.

37. If the temperature does not change, the average kinetic energy is not affected.

38. STP stands for standard temperature (0°C) and pressure (101.3 kPa or 1 atm).

39. At absolute zero, the motion of particles would theoretically cease.

40. The average kinetic energy triples.

LESSON 13.2

41. The particles in a gas are relatively far apart compared to the particles in a liquid. Because of the extra space between particles, a gas is less dense and easier to compress.

42. In both cases, particles with sufficient kinetic energy move from the liquid to the vapor phase. In a closed container, a dynamic equilibrium is set up between the contained liquid and its vapor.

43. Two opposing processes are occurring at identical rates.

44. More molecules have enough energy to escape the attractions within the liquid.

45. No. In an open container, most of the particles that escape from the surface of the liquid as vapor do not condense back to liquid.

46. The average kinetic energy increases, which allows more vapor to form above the liquid.

47. The boiling point is the temperature at which the vapor pressure equals the external pressure. At the normal boiling point, the external pressure is 101.3 kPa.

48. **a.** about 50 mm Hg **b.** about 94°C
c. 760 mm Hg is standard pressure

49. Escaping molecules have more kinetic energy than the average. Thus, the average kinetic energy and temperature of the remaining molecules are lower.

LESSON 13.3

50. Ionic compounds generally have higher melting points than molecular solids do.

51. The particles have sufficient kinetic energy to overcome the attractive forces holding them in place.

52. The intermolecular attractions between molecules are weaker than the attractions between ions.

ASSESSMENT

Evaluate

UNDERSTAND CONCEPTS

55. The average kinetic energy of the molecules is greater because, by definition, a fever is a state of increased body temperature.

56. **a.** 121°C **b.** chloroform **c.** chloroform
d. The external pressure on ethanol would have to increase; the external pressure on ethanoic acid would have to decrease.
e. about 77°C

57. Evaporation is the conversion of a liquid to a gas or vapor when the liquid is below its boiling point. The vapor pressure is the force per unit area exerted by the vaporized particles on the walls of a sealed container. The boiling point is the temperature at which the vapor pressure of the liquid is equal to the external pressure.

58. Although the net amounts of vapor and liquid remain constant, some molecules are evaporating while an equal number of molecules are condensing.

59. **a.** 80°C **b.** 100°C

60. decrease; As the attractions become stronger, it becomes more difficult for molecules to overcome the attractions and vaporize.

61. **a.** liquid **b.** vapor **c.** liquid
d. vapor **e.** solid **f.** solid

62. Atmospheric pressure results from the collisions of particles in air with objects. There are fewer particles in a given volume of air at the top of a mountain than at sea level.

63. The Kelvin temperature is directly proportional to the average kinetic energy. As the temperature rises, the air particles speed up and increase in kinetic energy, which causes the raft to expand. As the temperature drops, the air particles slow down resulting in a decrease in kinetic energy, which causes the raft to not be fully inflated.

THINK CRITICALLY

64. When you draw on a straw, the pressure inside the straw is less than the pressure (atmospheric) on the liquid in the container. So liquid is pushed up the straw.

65. Possible answer: Since the beaker is an open container, the water should boil at 100°C at or close to sea level. Your partner probably misread the thermometer and should recheck the value.

66. Possible answers: Odors will travel through a room; ink will spread throughout a beaker of water.

67. The average kinetic energy is the same, because the temperature is the same.

68. No. Collisions between large objects involve some loss of kinetic energy to heat.

69. Because the evaporation of perspiration is an endothermic process the skin is cooled.

Understand Concepts

***55.** What happens to the average kinetic energy of the water molecules in your body when you have a fever?

56. Refer back to Figure 13.9 to answer the following questions.
a. What is the normal boiling point of ethanoic acid?
b. Which liquid has the highest vapor pressure at 40°C?
c. At standard atmospheric pressure, which of the substances are in the gaseous state at 70°C?
d. Water boils at 100°C at standard pressure. How would the pressure on ethanol and on ethanoic acid have to change for these liquids to boil at 100°C?
e. Mount McKinley in Alaska is the tallest peak in North America at 6194 m. The atmospheric pressure at its peak is 44 kPa. What is the boiling point of water at the peak of Mount McKinley?

57. Describe the evaporation process, vapor pressure, and boiling point.

58. Why is the equilibrium that exists between a liquid and its vapor in a closed container called a dynamic equilibrium?

59. The table gives the vapor pressure of isopropyl alcohol at various temperatures. Graph the data. Use a smooth curve to connect the data points.

Temperature (°C)	Vapor pressure (kPa)
0	1.11
25	6.02
50	23.9
75	75.3
100	198
125	452

a. What is the estimated normal boiling point of isopropyl alcohol?
b. What is the boiling point of isopropyl alcohol when the external pressure is increased to twice standard pressure?

***60.** In a series of liquids, as the intermolecular forces of attraction strengthen, would you expect the vapor pressure to increase or decrease? Explain.

61. Predict the physical state of each substance at the specified temperature. Use the melting point and boiling point data from the table below.
a. phenol at 99°C
b. ammonia at −25°C
c. methanol in an ice-water bath
d. methanol in a boiling-water bath
e. ammonia at −100°C
f. phenol at 25°C

Substance	Melting Point (°C)	Boiling Point (°C)
ammonia	−77.7	−33.4
methanol	−97.7	64.7
water	0	100
phenol	40.9	181.9

62. Why is atmospheric pressure much lower on the top of a mountain than it is at sea level?

***63.** A fully inflated raft is left outside overnight. The next morning the raft is not fully inflated. As the air temperature rises during the day, the raft expands to the size it was the night before. Assuming that the amount of air inside the raft did not change, use kinetic theory to explain why the size of the raft changes.

Think Critically

64. **Relate Cause and Effect** What role does atmospheric pressure play when someone is drinking a liquid through a straw?

***65.** **Analyze Data** Your lab partner measures the boiling point of water in an open beaker as 108.2°C. You know that water can be made to boil at this temperature, but you still ask your partner to repeat the measurement. Explain.

66. **Infer** What everyday evidence suggests that all matter is in constant motion?

67. **Explain** Is the average kinetic energy of the particles in a block of ice at 0°C the same as or different from the average kinetic energy of the particles in a gas-filled weather balloon at 0°C? Explain.

68. **Infer** Can objects that are large enough for you to see collide elastically? Explain.

69. **Apply Concepts** How does perspiration help cool your body on a hot day?

70. **Relate Cause and Effect** Why do different liquids have different normal boiling points?

71. **Explain** A liquid-vapor equilibrium exists in a container. Explain why the equilibrium vapor pressure in the container is not affected when the volume of the container is changed.

*72. **Analyze Data** A teacher wants to demonstrate that unheated water can boil at room temperature in a beaker within a bell jar connected to a vacuum pump. However, the vacuum pump is faulty and can reduce pressures only to 15 kPa. Can the teacher use this pump to perform the demonstration successfully? Explain your answer.

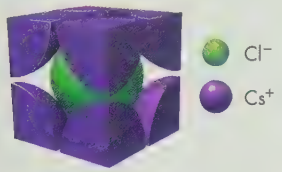
73. **Compare** You have two sealed jars of water at the same temperature. In the first jar, there is a large amount of water. In the second jar, there is a small amount of water. Explain how the vapor pressure can be the same in both jars.

74. **Draw Conclusions** Why are pressure cookers recommended for cooking at high altitude?

75. **Propose a Solution** A mixture of gases contains oxygen, nitrogen, and water vapor. What physical process could you use to remove the water vapor from the sample?

Enrichment

*76. **Apply Concepts** Relative humidity is defined by the following equation



$$\text{Relative humidity} = \frac{(a)}{(b)} \times 100\%$$

where (a) is the pressure of water vapor in the air and (b) is the equilibrium vapor pressure of water in the air at the same temperature. Can the relative humidity exceed 100%? Explain.

77. **Use Models** The ions in sodium chloride are arranged in a face-centered cubic pattern. Draw a layer of ions in a sodium chloride crystal.

78. **Use Models** Using Figure 13.12, identify the crystal systems described below.
- a. three unequal edges meet at right angles
- b. three equal edges with three equal angles that are not right angles
- c. two equal edges and one unequal edge meet at right angles
- d. three unequal edges do not meet at right angles
- e. three equal edges meet at right angles

*79. **Use Models** Use this drawing to answer the questions.

- a. What type of unit cell is in a lattice of cesium chloride?
- b. What is the coordination number of Cs^+? (*Hint:* Refer back to Section 7.2 for the definition of coordination number.)
- c. Based on the diagram, what is the formula of cesium chloride? Explain your answer.

80. **Predict** The solid-liquid equilibrium line in the phase diagram of a given substance slants to the right. How is the substance's freezing point affected by increased pressure?

CHEMYSTERY

Foggy Car Windows

Car windows fog up because of condensation. When warm, moist air comes into contact with a cold surface, the water vapor in the air condenses into liquid drops on the cold surface. When it's cold outside, your body and breath warm the air inside the car. This warm, moist air comes in contact with the cold surface of the car window, causing it to fog up. Using a car heater increases the amount of moisture in the air, since warm air can hold more water vapor than cold air. The amount of moisture in the air will also be higher on a rainy day because some of the water on the passengers evaporates. An air conditioner cools and removes moisture from the air.

81. **Explain** Describe why opening a window can also help defog a car windshield.

82. Connect to the **BIG IDEA** How does the average motion of the water molecules change as water vapor condenses on a car window? Why does the motion change?

Explain

CHEMYSTERY

APPLY CONCEPTS After students have read through the CHEMystery, call on volunteers to summarize why car windows fog up when it is cold or when it is raining, and why the fog goes away when you turn on the air conditioner. **Ask** On a cold day, is condensation more likely to form if you have cold air or warm air inside a car? Why? *(Condensation is more likely to form if you have warm air inside the car. When the water vapor inside the car touches the cold window, it cools and changes to a liquid.)* **Ask** Why does warm air hold more water vapor than cold air? *(The higher the air temperature is the higher the average kinetic energy of the water molecules is. As a result, more water molecules will have enough kinetic energy to overcome the forces of attraction and evaporate.)*

CHEMYSTERY ANSWERS

81. When you open a car window, fresh air will enter the car replacing some of the moist air inside of the car.

82. The average kinetic energy of the water molecules decreases as the water vapor condenses on the car window. The motion of the water molecules decreases as a result.

Answers

70. The intermolecular attractions in some compounds are stronger than in others.

71. The vapor pressure depends only on the kinetic energy of the escaping molecules.

72. No. At 15 kPa, water would boil at a temperature of about 50°C, which is much higher than room temperature.

73. The kinetic energy of the molecules in the vapor is the same in both cases; so the vapor pressure is the same.

74. At high altitude, the boiling point of water is less than 100°C because the atmospheric pressure is lower. The increased pressure in the pressure cooker increases the temperature at which water boils.

75. condensation of the water vapor on a cold surface

ENRICHMENT

76. No; if (a) > (b) then water vapor will condense at a greater rate than the liquid evaporates.

77. $Na^+Cl^-Na^+Cl^-$
$Cl^-Na^+Cl^-Na^+$
$Na^+Cl^-Na^+Cl^-$
$Cl^-Na^+Cl^-Na^+$

78. **a.** orthorhombic **b.** rhombohedral **c.** tetragonal **d.** triclinic **e.** cubic

79. **a.** body-centered cubic **b.** 8 **c.** CsCl (one Cl^- ion and 8 × 1/8 equals one Cs^+ ion)

80. The freezing point increases.

Cumulative Review

83. inversely

84. **a.** S **b.** K

85. **a.** $1s^2 2s^2 2p^6 3s^2 3p^6$ **b.** $1s^2 2s^2 2p^6 3s^2 3p^6$ **c.** $1s^2$

86. **a.** 2 **b.** 2

87. dispersion forces, dipole interactions, hydrogen bonds

88. **a.** Cu_2SO_3 **b.** HNO_2

89. **a.** CO **b.** PBr_3

90. **a.** Fe^{3+} **b.** Cd^{2+}

91. **a.** 53.7% Fe **b.** 34.6% Al

92. **a.** 13.9 mol SO_2 **b.** 0.0472 mol NH_3

93. **a.** 51.2 g Cl_2O_7 **b.** 3.81×10^4 mL H_2O

94. **a.** 0.38 mol CO_2 **b.** 3.73 mol NH_3

95. $H_2S(aq) + Cd(NO_3)_2(aq) \rightarrow 2HNO_3(aq) + CdS(s)$

96. **a.** $V_2O_5 + 2H_2 \rightarrow V_2O_3 + 2H_2O$

b. $(NH_4)_2 + Cr_2O_7 \rightarrow Cr_2O_3 + N_2 + 4H_2O$

97. **a.** Mg **b.** Li

98. **a.** combination **b.** combustion

99. **a.** 198 g H_2O **b.** 23 mol **c.** 144 g C

100. C_2H_4

101. 39.4 g FeS (0.448 mol)

102. 41.9%

Cumulative Review

83. How are the frequency and wavelength of light waves related?

84. Which atom in each pair has the larger atomic radius?

a. O and S **b.** K and Br

***85.** Write the electron configuration of each ion.

a. Ca^{2+} **b.** S^{2-} **c.** Li^+

86. How many unshared pairs of electrons are in each molecule?

a. H_2O **b.** CO

87. List the intermolecular attractions between molecules in order of increasing strength.

a. dispersion forces
b. hydrogen bonds
c. dipole interactions

88. Write a correct formula for each compound.

a. copper(I) sulfite **b.** nitrous acid

89. Identify the binary molecular compound in each pair of substances.

a. NaCl or CO **b.** PBr_3 or LiOH

90. Write formulas for these ions.

a. iron(III) **b.** cadmium

91. Calculate the percent by mass of the metal in each compound.

a. Fe_2S_3 **b.** $Al(OH)_3$

92. How many moles are there in each sample?

a. 888 g of sulfur dioxide
b. 2.84×10^{22} molecules of ammonia

***93.** Perchloric acid forms by the reaction of water with dichlorine heptoxide.

$$Cl_2O_7 + H_2O \longrightarrow 2HClO_4$$

a. How many grams of Cl_2O_7 react with an excess of H_2O to form 56.2 g of $HClO_4$?
b. How many mL of water are needed to form 3.40 mol $HClO_4$?

94. How many moles are there in each sample?

a. 8.6 L CO_2 (at STP) **b.** 63.4 g NH_3

***95.** When hydrogen sulfide gas is bubbled into a solution of cadmium nitrate in water, the products are nitric acid and a precipitate of cadmium sulfide. Write a balanced equation for the reaction. Include physical states for all reactants and products. (Hydrogen sulfide gas is soluble in water.)

96. Balance these equations.

a. $V_2O_5 + H_2 \longrightarrow V_2O_3 + H_2O$
b. $(NH_4)_2Cr_2O_7 \longrightarrow Cr_2O_3 + N_2 + H_2O$

97. List the metal that ranks higher in the activity series of metals.

a. magnesium or mercury
b. potassium or lithium

98. Classify each reaction as a combination, decomposition, single-replacement, double- replacement, or combustion.

a. $2Li(s) + Br_2(l) \longrightarrow 2LiBr(s)$
b. $2C_2H_6(g) + 7O_2(g) \longrightarrow 4CO_2(g) + 6H_2O(g)$

***99.** The complete decomposition of sucrose (table sugar) caused by strong heating may be represented by this equation.

$$C_{12}H_{22}O_{11}(s) \longrightarrow 11H_2O(l) + 12C(s)$$

For the decomposition of 1.00 mol of sucrose:

a. How many grams of H_2O are produced?
b. What is the total number of moles of products produced?
c. How many grams of C are produced?

***100.** Hydrogen reacts with ethene (C_2H_4) to form ethane (C_2H_6).

$$C_2H_4 + H_2 \longrightarrow C_2H_6$$

What is the limiting reagent when 40.0 g C_2H_4 reacts with 3.0 g H_2?

101. Iron(II) sulfide is produced when iron is heated with sulfur.

$$Fe(s) + S(s) \xrightarrow{\Delta} FeS(s)$$

What is the theoretical yield of FeS if 25.0 g Fe is heated with 32.0 g S?

102. What is the percent yield in Question 101 if 16.5 g of FeS is produced?

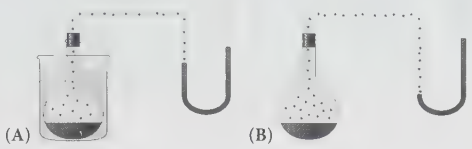
Tips for Success



Interpreting Graphs A line graph helps you see the relationship between two variables. Before you answer a question about a graph, identify the variables and the general relationship between the variables based on the shape of the curve.

Use the graph to answer Questions 1 and 2.

1. What is the normal boiling point of ethanol?
2. Can chloroform be heated to 90°C in an open container?
3. Which sequence has the states of CH_3OH correctly ordered in terms of increasing average kinetic energy?
   (A) $CH_3OH(s)$, $CH_3OH(g)$, $CH_3OH(l)$
   (B) $CH_3OH(g)$, $CH_3OH(l)$, $CH_3OH(s)$
   (C) $CH_3OH(l)$, $CH_3OH(g)$, $CH_3OH(s)$
   (D) $CH_3OH(s)$, $CH_3OH(l)$, $CH_3OH(g)$

Use the drawing to answer Questions 4–6. The same liquid is in each flask.

4. In which flask is the vapor pressure lower? Give a reason for your answer.
5. In which flask is the liquid at the higher temperature? Explain your answer.
6. How can the vapor pressure in each flask be determined?

For each question below, there are two statements. Decide whether each statement is true or false. Then decide whether Statement II is a correct explanation for Statement I.

	Statement I		Statement II
7.	In an open container, the rate of evaporation of a liquid always equals the rate of condensation.	BECAUSE	A dynamic equilibrium exists between the liquid and its vapor in an open container.
8.	Water boils at a temperature below 100°C on top of a mountain.	BECAUSE	Atmospheric pressure decreases with an increase in altitude.
9.	The temperature of a substance always increases as heat is added to the substance.	BECAUSE	The average kinetic energy of the particles in a substance increases with an increase in temperature.
10.	Solids have a fixed volume.	BECAUSE	Particles in a solid cannot move.
11.	Gases are more compressible than liquids.	BECAUSE	There is more space between particles in a gas than between particles in a liquid.

Materials List

For the Student

Quick Lab p 467
- 6 effervescent antacid tablets
- 3 rubber balloons
- plastic medicine dropper
- water
- watch
- metric tape measure
- graph paper

Small-Scale Lab p 475
- clear plastic up
- dropper bottles with bromthymol blue
- hydrochloric acid and sodium hydrogen sulfite solutions
- ruler
- cotton swab
- NaOH, NH4Cl, KI, and $NaNO_2$ (optional)

For the Teacher

Teacher Demo p 452
- 2 identical glass containers
- 2 different sizes of beads

Teacher Demo p 458
- vacuum pump
- bell jar
- marshmallows

Class Activity p 460
- 2 large vats
- ice water
- hot water
- inflated bicycle tire

Class Activity p 470
- balance
- 4 marbles
- 2 buttons
- 3 pennies
- 4 nickels

Teacher Demo p 472
- 2 round identical balloons
- helium
- metric tape measure

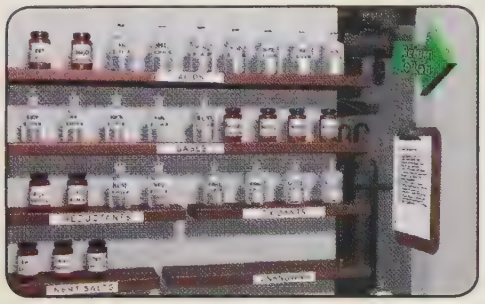
14.2 Virtual Chem Lab 11: Pressure-Volume Relationship for Gases
14.2 Virtual Chem Lab 12: Temperature Volume Relationship for Gases
14.3 Virtual Chem Lab 13: Derivation of the Ideal Gas Law
14.3 Virtual Chem Lab 14: Ideal vs. Real Gases



What's Online

Students access guided, step-by-step tutorials for solving various gas law problems.

Students can practice key problem-solving skills in an online problem set.

Identify the students that struggle with math by assigning an online math skills diagnostic test. These students can then improve and practice math skills by using the MathXL tutorial system.

Students go on an animated virtual lab tour in which gases are studied in a simulated laboratory environment.

Student watch animations of a selected figures from the chapter followed by questions to check for understanding.

watch an overview of a key chapter concept using real-world contexts and concrete examples and analogies. Each activity includes an interactive animation followed by analysis questions.

Aviators known as cluster balloonists rise above the clouds by harnessing themselves to balloons filled with helium gas.

IN ACADEMIC STANDARDS for SCIENCE

Nature of Science

- Explain how scientific knowledge can be used to guide decisions on environmental and social issues.

Standard 5: Behavior of Gases

C.5.1 Use kinetic molecular theory to explain changes in gas volumes, pressure, moles, and temperature.

C.5.2 Using the ideal gas equation of state, $pv = nRT$, calculate the change in one variable when another variable is changed and the others are held constant. Distinguish among isothermal, isobaric, isometric, and adiabatic processes.

Also covered C.4.2, C.5.3, C.6.2

Focus on ELL

1 CONTENT AND LANGUAGE Clarify for students that the words *property(ies)*, *gas(es)*, and *law(s)* each have both a common and a scientific meaning. Explain how to create the plural form for each. Assign students to three groups. Have each group complete a Frayer Model diagram for one word—with a definition, characteristics, an example, and a nonexample. Have each group teach the word to the class.

BEGINNING

LOW Create a symbol or drawing to represent each word. If you can, create a native language definition.

HIGH Write each word and introduce it to the class by pointing and saying it aloud.

INTERMEDIATE: LOW/HIGH Brainstorm examples and nonexamples and present them to the class.

ADVANCED: LOW/HIGH Write each definition and present it to the class. Explain to the class how the examples represent the word.

BIG IDEA

KINETIC THEORY

Essential Questions:

1. *How do gases respond to changes in pressure, volume, and temperature?*
2. *Why is the ideal gas law useful even though ideal gases do not exist?*

CHEMYSTERY

Under Pressure

Just after 2 P.M., Becki completes her eighth scuba dive over a four-day period off the coast of Belize. After the dive, she feels fine.

A few hours later at dinner, Becki feels tired. She thinks that her fatigue is probably due to the many hours she had spent swimming during her vacation. But she also begins to feel itchy and notices a blotchy rash on her skin. Did she get stung by a sea creature during her last dive? Becki decides to go back to her hotel room to get some rest. As she is walking, she begins to feel severe pains in the joints of her arms and legs and feels achy all over her body. Becki feels like she is coming down with the flu, but she realizes that her symptoms are related to her dives. What is wrong with Becki?

▶ Connect to the BIG IDEA As you read about the behavior of gases, think about what may have caused Becki's symptoms.

Introduce the Chapter

IDENTIFY PRECONCEPTIONS Students often enter into the study of gases with preconceptions. Use the following activities to show them that gases such as air—even though invisible—are matter and are made up of atoms and molecules that take up space.

Activity 1 *You'll need a bottle and a balloon.* **Ask** What's inside the bottle? *(Most will say "nothing.")* Hold the top of the balloon and push the bottom into the bottle. Stretch the top of the balloon over the mouth of the bottle and try to inflate the balloon by blowing into it. The result is that the balloon expands only slightly because the bottle is filled with air. **Ask** Why doesn't the balloon expand completely? *(because the bottle is filled with air)*

Activity 2 Take the balloon out of the bottle, inflate it, and tie it off. Then try to compress it. **Ask** Why does an inflated balloon resist being compressed? *(because the balloon is filled with air)*

UbD

Understanding by Design

Students are building toward understanding gas behavior by using the kinetic theory of gases. **PERFORMANCE GOALS** At the end of Chapter 14, students will be able to answer the essential questions by applying their knowledge of gas laws. Students will also be able to calculate a value for an unknown gas by using the ideal gas law.

ESSENTIAL QUESTIONS Read the essential questions aloud. **Ask** Compared with solids and liquids, what's unique about gases? *(Gas particles are much farther apart from each other than particles in solids or liquids.)* **Ask** Can you predict how this feature might affect a gas if there are changes in pressure, volume, and temperature? Why do you suppose we study ideal gases, which don't exist? *(Engage students in a discussion of reasonable answers.)*

BIG IDEA Use the photo of the cluster balloonist to help students connect to the concepts they will learn in this chapter. Activate prior knowledge by reviewing kinetic theory. **Ask** What's unique about helium that makes it ideal for these balloonists? *(Helium is less dense than any other gas except hydrogen and is less dense than air.)* **Ask** What do you think happens to the balloons as they rise? *(They expand because the outside air pressure decreases.)*

CHEMYSTERY Have students read over the CHEMystery. Connect the CHEMystery to the Big Idea of kinetic theory by explaining that the behavior of gases can be predicted. The gas laws describe how gases respond to changes in pressure, volume, and temperature. For example, as the pressure of a sample of gas at a constant temperature decreases, volume increases. Ask students to predict what happens to the pressure of the gases that Becki breathes in as she dives and then ascends back to the surface. As a hint, tell students that the pressure of the gases that Becki breathes in is the same as the pressure outside her body. As Becki dives deeper, the pressure outside her body increases. As she rises to the surface, the pressure decreases.

LESSON 14.1

Key Objectives

14.1.1 EXPLAIN why gases are easier to compress than solids or liquids are.

14.1.2 DESCRIBE the three factors that affect gas pressure.

Engage

CHEMISTRY & YOU Ask students to look at the photograph that opens the section. **Ask** What factors do you think affect the pressure of the air inside the ball? *(the temperature of the air in the ball; the volume of the ball)*

Activate Prior Knowledge

Point out that in this chapter, students will build upon their knowledge of kinetic theory to describe the behavior of gases. **Ask** What is kinetic energy? *(energy of motion)* How are temperature and kinetic energy related? *(Temperature is a measure of average kinetic energy.)*

Foundations for Reading

BUILD VOCABULARY Have students look up the meanings of the prefix *com- ("together")*, the word *press ("to act on with a steady force or weight")*, and the suffix *-ibility ("ability or tendency")*. Have them use these meanings to define *compressibility*.

IN ACADEMIC STANDARDS for SCIENCE

C.5.1 Use kinetic molecular theory to explain changes in gas volumes, pressure, moles, and temperature.

14.1 Properties of Gases

C.5.1 Kinetic molecular theory

CHEMISTRY & YOU

Q: *Why is there a recommended pressure range for the air inside a soccer ball?* In organized soccer, there are rules about the equipment used in a game. For example, in international competitions, the ball's mass must not be more than 450 grams and not less than 410 grams. The pressure of the air inside the ball must be no lower than 0.6 atmospheres and no higher than 1.1 atmospheres at sea level.

In this lesson, you will study variables that affect the pressure of a gas. As you will discover, gas pressure is useful in a number of different objects, including auto air bags, inflatable rafts, aerosol sprays, and, yes, soccer balls.

Key Questions

Why are gases easier to compress than solids or liquids?

What are the three factors that affect gas pressure?

Vocabulary

- compressibility

Compressibility

Why are gases easier to compress than solids or liquids?

Recall from Chapter 13 that a gas can expand to fill its container, unlike a solid or liquid. The reverse is also true. Gases are easily compressed, or squeezed into a smaller volume. **Compressibility** is a measure of how much the volume of matter decreases under pressure.

The compressibility of a gas plays an important role in auto safety. When a car comes to a sudden stop, the people in the car will continue to move forward unless they are restrained. The driver and any passengers are more likely to survive a collision if they are wearing seat belts to restrict their forward movement. Cars also contain air bags as a second line of defense. A sudden reduction in speed triggers a chemical reaction inside an air bag. One product of the reaction is nitrogen gas, which causes the bag to inflate. An inflated air bag keeps the driver from colliding with the steering wheel. On the front passenger side of the car, an inflated air bag keeps a passenger from colliding with the dashboard or windshield.

Why does a collision with an inflated air bag cause much less damage than a collision with a steering wheel or dashboard? When a person collides with an inflated air bag, as shown in Figure 14.1, the impact forces the molecules of nitrogen gas in the bag closer together. The compression of the gas absorbs the energy of the impact.

Focus on ELL

1 CONTENT AND LANGUAGE Ask students to state the key questions in their own words. Have pairs make and use flashcards for key vocabulary. They should write the word on one side and a definition, visual, and sentence with the word on the other. Allow students with limited English to use their native languages for support.

2 FRONTLOAD THE LESSON Have students discuss games they've played that involve inflatable balls. Ask them what differences they've noticed, if any, when balls are underinflated. Direct them to the information in Chemistry & You.

3 COMPREHENSIBLE INPUT Explain Figure 14.5 and restate information in its caption as needed. Read the question aloud, and draw a cause-and-effect chart on the board. As you discuss the question, have students fill in the chart.

Figure 14.1 Compression of a Gas
Because gases can be compressed, the air bag absorbs some of the energy from the impact of a collision. Air bags work best when combined with seat belts.
Describe *What happens to the gas molecules inside an air bag when a driver collides with the bag?*

Kinetic theory can explain why gases are compressed more easily than liquids or solids. **Gases are easily compressed because of the space between the particles in a gas.** Remember that the volume of the particles in a gas is small compared to the overall volume of the gas. So the distance between particles in a gas is much greater than the distance between particles in a liquid or solid. Under increased pressure, the particles in a gas are forced closer together, or compressed.

Figure 14.2 is a model of identical air samples in two different containers. Only oxygen and nitrogen—the two main gases in air—are represented. Each container has 8 nitrogen molecules and 2 oxygen molecules. In the larger container, the molecules are farther apart. In the smaller container, the air sample is compressed, and the molecules are closer together. Note that at STP, the distance between particles in an enclosed gas is about 10 times the diameter of a particle. However, it isn't practical to represent the actual distances between particles in all the molecular drawings of gases in this book. In order for the drawings to fit easily on a page, the particles are drawn closer together.

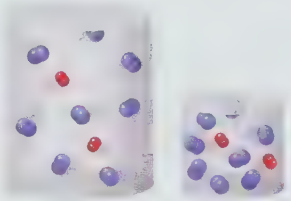

Figure 14.2 Modeling Air at Two Different Pressures
Air is primarily a mixture of two gases, nitrogen (N_2) and oxygen (O_2). A sample of air contains about 4 nitrogen molecules for every oxygen molecule.

Factors Affecting Gas Pressure

What are the three factors that affect gas pressure?

Kinetic theory can help explain other properties of gases, such as their ability to expand and take the shape and volume of their containers. Recall these assumptions about the particles in a gas. The particles move along straight-line paths until they collide with other particles or the walls of their container. The motion of the particles is constant and random. Because kinetic theory assumes there are no significant forces of attraction or repulsion among particles in a gas, particles in a gas can move freely.

Four variables are generally used to describe a gas. The variables and their common units are pressure (P) in kilopascals, volume (V) in liters, temperature (T) in kelvins, and the number of moles (n). **The amount of gas, the volume, and the temperature are factors that affect gas pressure.**

Learn more about gas properties online

READING STRATEGY For each paragraph in this section, have students identify the main idea. They can later use their list of main ideas as a study guide.

Explain

Compressibility

USE VISUALS Figure14.2 illustrates the amount of space in a gas under ordinary conditions. Ask students to estimate the amount of space occupied by the molecules in the figure. *(Students are likely to say less than 5 percent.)* Explain that for practical reasons, in most drawings the particles will be too close together for their depicted size. Remind students how small the actual particles are and how many particles there are in a small volume of gas.

Factors Affecting Gas Pressure

APPLY CONCEPTS Help students review their knowledge of kinetic theory. How would you describe gas pressure? *(Gas pressure is the result of collisions of particles with their container.)* How does increasing the number of particles in a gas affect the pressure? *(The more particles colliding with the walls of a container, the higher the pressure.)*

MAKE A CONNECTION Lead the class in a discussion of the four variables—volume, temperature, pressure, and number of moles—used to describe a gas. Discuss how the properties of gases lead to some unique uses of them. For example, because the particles in a gas are relatively far apart, gases are poor thermal conductors and are used for insulation between the glass panes in double-paned windows.

Professional Development Note

Gas and Momentum

The particles in a gas have momentum, the product of their mass and velocity (mv). The pressure exerted by a gas in a given volume is proportional to the average kinetic energy of its molecules ($1/2\ mv^2$). The mass of the particles is constant, so any change in momentum is due to a change in velocity. A rise in temperature reflects a rise in average kinetic energy, corresponding to an increase in momentum and pressure.

Answers

FIGURE 14.1 The gas molecules inside the air bag are forced closer together as a result of the impact. (The air bag eventually deflates when the compressed gas escapes through small holes in the bag.)

Explain

USE VISUALS Point out Figures 14.3 and 14.4 to students. Make sure they understand the difference between a container with a volume that can vary (within limits), such as a balloon or raft, and a rigid container with a constant volume.

Explore

Teacher Demo

PURPOSE Students use an analogy to infer the effect of particle size on gas pressure.

MATERIALS 2 identical glass containers, 2 different sizes of beads

PROCEDURE Add small beads to a glass container until it is approximately one-eighth full. Add the same number of larger beads to an identical container. Have the students assume that the beads represent particles of gases in sealed containers at the same temperature. Ask students to compare the pressures in the two containers.

EXPECTED OUTCOME The pressures will be identical because both gases contain the same number of particles with the same average kinetic energy in the same volume.

Figure 14.3 Gas in a Flexible Container The volume of an air-filled raft is much larger than its volume before it was inflated. Using a pump to force air into a raft increases the pressure of the air inside the raft.

Compare *How does an underinflated raft compare with a fully inflated raft? Why do you think an underinflated raft might be dangerous to ride in?*

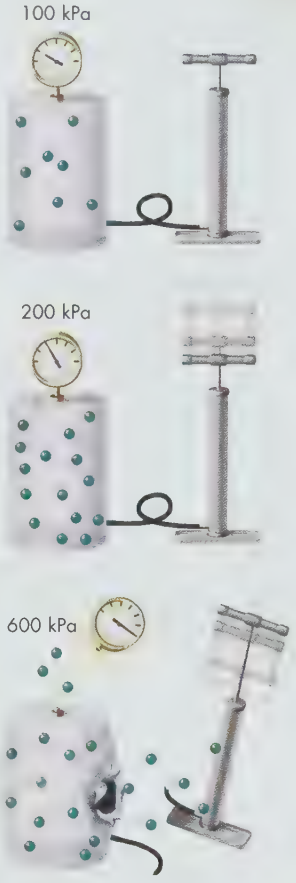

Figure 14.4 Gas in a Rigid Container When a gas is pumped into a closed rigid container, the pressure increases as more particles are added. If the number of particles is doubled, the pressure will double.

Amount of Gas

An air-filled raft blasts through a narrow opening between rocks and plummets over a short waterfall into churning white water below. The raft bends and twists, absorbing some of the pounding energy of the river. The strength and flexibility of the raft rely on the pressure of the gas inside the raft. The raft must be made of a material that is strong enough to withstand the pressure of the air inside the raft. The material must also keep air from leaking out of the raft. The volume of the inflated raft in Figure 14.3 is dramatically larger than the volume of the raft before it is inflated. As air is added, the raft expands to its intended volume. The pressure of the air inside the raft keeps the raft inflated.

You can use kinetic theory to predict and explain how gases will respond to a change of conditions. If you inflate an air raft, for example, the pressure inside the raft will increase. Collisions of gas particles with the inside walls of the raft result in the pressure that is exerted by the enclosed gas. By adding gas, you increase the number of particles. Increasing the number of particles increases the number of collisions, which explains why the gas pressure increases.

Figure 14.4 shows what happens when gas is added to an enclosed, rigid container. Because the container is rigid, the volume of the gas is constant. Assume also that the temperature of the gas does not change. Under these conditions, doubling the number of particles of gas doubles the pressure. Tripling the number of particles triples the pressure, and so on. With a powerful pump and a strong container, you can generate very high pressures by adding more and more gas. However, once the pressure exceeds the strength of the container, the container will burst. Removing gas from a rigid container has the opposite effect. As the amount of gas is reduced, the pressure inside the container is reduced. If the number of particles in the container were cut in half, the pressure would drop by half.

Differentiated Instruction

L1 STRUGGLING STUDENTS Have students draw a balloon and use circles to represent gas particles. Then ask students to draw a smaller balloon with the same number of particles to illustrate what happens to the gas particles in the balloon when it's compressed.

ELL ENGLISH LANGUAGE LEARNERS Assign students to groups of three. Have each student silently read one of the paragraphs in the sections titled Amount of Gas, Volume, and Temperature. Ask students to cover the page and restate to the group one fact they read.

L3 ADVANCED STUDENTS Ask students to explain why a fully inflated polyester film balloon appears underinflated after moving from a warm place to a cool one.

452 Chapter 14 • Lesson 1

If the pressure of the gas in a sealed container is lower than the outside air pressure, air will rush into the container when the container is opened. This movement causes the whoosh you hear when you open a vacuum-packed container. When the pressure of a gas in a sealed container is higher than the outside air pressure, the gas will flow out of the container when the container is unsealed.

The operation of an aerosol can depends on the movement of a gas from a region of high pressure to a region of lower pressure. Aerosol cans may contain whipped cream, hair mousse, or spray paint. Figure 14.5 shows how a can of spray paint works. The can contains a gas stored at high pressure. The air outside the can is at a lower pressure. Pushing the spray button creates an opening between the inside of the can and the air outside. The gas flows through the opening to the lower pressure region outside. The movement of the gas propels, or forces, the paint out of the can. As the gas is depleted, the pressure inside the can decreases until the gas can no longer propel paint from the can.

Volume You can raise the pressure exerted by a contained gas by reducing its volume. The more the gas is compressed, the more pressure the gas exerts inside the container. When gas is in a cylinder, as in an automobile engine, a piston can be used to reduce its volume. The snug-fitting piston keeps gas from escaping as the cylinder moves down and up.

Figure 14.6 shows a cylinder of gas under two different conditions. When the cylinder has a volume of 1 L, the gas exerts a pressure of 100 kPa. When the volume is halved to 0.5 L, the pressure is doubled to 200 kPa. Increasing the volume of the contained gas has the opposite effect. If the volume is doubled, the particles can expand into a volume that is twice the original volume. With the same number of particles in twice the volume, the pressure of the gas is cut in half.

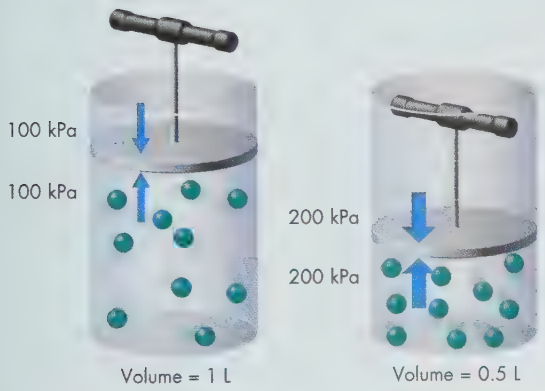

Figure 14.6 Pressure and Volume
A piston can be used to force a gas in a cylinder into a smaller volume. When the volume is decreased, the pressure the gas exerts is increased.
Interpret Diagrams ***What happens to the gas pressure when the volume is reduced from 1 L to 0.5 L?***

Figure 14.5 Aerosol Can
The pressure of the gas inside a new can of spray paint is greater than the air pressure outside the can. When gas rushes though an opening in the top of the can, it propels, or forces, paint out of the can. As the can is used, the pressure of the propellant decreases.
Relate Cause and Effect ***What happens when the pressure of the propellant equals the air pressure outside the can?***

UbD Check for Understanding

The Essential Question **How do gases respond to changes in pressure, volume, and temperature?**

Assess students' understanding of gas pressure. **Ask** What would be the effect on pressure if the number of particles of a gas in a closed container were tripled? *(The pressure would triple.)* **Ask** What effect would doubling the volume of an enclosed gas have on the pressure? *(The pressure would decrease by one half.)* **Ask** How does the pressure of an enclosed gas change with increasing temperature? *(The number and force of collisions increase with temperature, and the pressure increases.)*

ADJUST INSTRUCTION If students are having difficulty answering, refer them to Figures 14.4, 14.6, and 14.7 for review, and then ask the questions again.

Explain

START A CONVERSATION Point out Figure 14.5. Ask students to think about why the instructions on an aerosol can of paint say to hold it upright while spraying. If the can is not held upright, what material will come out of the can? *(the propellant)*

How would the loss of propellant affect the use of the can when it is later held upright and sprayed? *(The amount of propellant would be reduced, so there would be less pressure to force the paint out of the can.)*

USE VISUALS Figure 14.6 is the first of the drawings that show a piston and cylinder. If possible, show students an actual piston and cylinder. Explain how the tight fit of the piston in the cylinder keeps the gas contained and, thus, able to be compressed.

What will happen to the pressure in the cylinder as the volume is decreased? *(Pressure will increase.)* Point out that the number of particles in both diagrams is the same. Why does the pressure of a contained gas double when the volume is reduced by one half? *(Reducing the volume by one half doubles the number of simultaneous collisions of particles with the walls of the piston, doubling the pressure.)*

Answers

FIGURE 14.3 An underinflated raft has a smaller volume and is less rigid than a fully inflated raft. An underinflated raft would be more susceptible to folding or collapsing during the ride.

FIGURE 14.5 The gas can no longer propel the product out of the can.

FIGURE 14.6 The pressure is doubled from 100kPa to 200 kPa.

Explain

CHEMISTRY & YOU A ball that is properly inflated will rebound faster and travel farther than a ball that is underinflated. If the pressure is too high, the ball may burst when it is kicked.

Extend

Connect to PHYSICS

BALLS IN SPORTS Have students research the relationship between gas compressibility and the transfer of kinetic energy in inflatable balls such as soccer balls and basketballs. Ask them to write a brief report comparing and contrasting energy transfer in inflatable balls to energy transfer in solid core balls such as baseballs.

Evaluate

Informal Assessment

Divide the class into two teams. Have each team write five to eight questions about factors that affect gas pressure. After all the questions are put into a box, have Team 1 and then Team 2 draw a question and attempt to answer it in one minute. Continue for several rounds. The team with the most correct answers wins. Then have students complete the 14.1 Lesson Check.

Reteach

Help students make a table to summarize how gas pressure changes as variables increase or decrease. Label the rows *Volume*, *Temperature*, and *Number of Particles*. Label the columns *Increase* and *Decrease*. Have students use up or down arrows to complete the table.

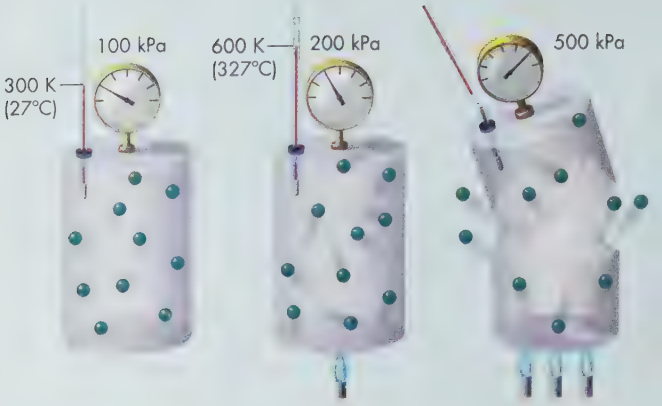

Figure 14.7 Temperature and Pressure
An increase in temperature causes an increase in the pressure of an enclosed gas. The container can explode if there is too great an increase in the gas pressure.

CHEMISTRY & YOU

Q: *Which do you think would travel farther if kicked with the same amount of force: a properly inflated soccer ball or an underinflated soccer ball? What might happen to an overinflated soccer ball if you kicked it too hard?*

Temperature A sealed bag of potato chips bulges at the seams when placed in a sunny location. The bag bulges because an increase in the temperature of an enclosed gas causes an increase in its pressure. You can use kinetic theory to explain what happens. As a gas is heated, the temperature increases and the average kinetic energy of the particles in the gas increases. Faster-moving particles strike the walls of their container with more energy.

Look at Figure 14.7. The volume of the container and the amount of gas is constant. When the Kelvin temperature of the enclosed gas doubles from 300 K to 600 K, the pressure of the enclosed gas doubles from 100 kPa to 200 kPa. A gas in a sealed container may generate enormous pressure when heated. For that reason, an aerosol can, even an "empty" one, may explode if thrown onto a fire.

By contrast, as the temperature of an enclosed gas decreases, the pressure decreases. The particles, on average, move more slowly and have less kinetic energy. They strike the container walls with less force. Halving the Kelvin temperature of a gas in a rigid container decreases the gas pressure by half.

14.1 LessonCheck

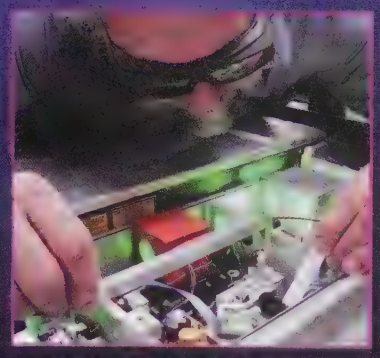
1. **Review** Why is a gas easy to compress?
2. **Identify** List three factors that can affect gas pressure.
3. **Compare and Contrast** Why does a collision with an air bag cause less damage than a collision with a steering wheel?
4. **Explain** How does a decrease in temperature affect the pressure of a contained gas?
5. **Apply Concepts** If the temperature is constant, what change in volume would cause the pressure of an enclosed gas to be reduced to one quarter of its original value?
6. **Apply Concepts** Assuming the gas in a container remains at a constant temperature, how could you increase the gas pressure in the container a hundredfold?
7. **Summarize** Write a paragraph explaining how a pressurized garden sprayer works. Make sure to describe what happens to the air pressure inside the sprayer as it is pumped by hand.

BIG IDEA KINETIC THEORY

8. Use the kinetic theory of gases to explain why a gas can be easily squeezed into a smaller volume.

Lesson Check Answers

1. Gases are easily compressed because of the space between gas particles.
2. temperature, pressure, and amount of gas
3. Because the gas in the inflated air bag can be compressed, the bag absorbs some of the energy from the impact of a collision. The solid steering wheel cannot do this.
4. If the temperature decreases, the pressure will also decrease.
5. The volume would need to increase by a factor of four.
6. Increase the amount of gas in the container a hundredfold.
7. Sample answer: The pressure of the gas inside the sprayer is greater than atmospheric pressure. As the gas propels the contents out, the number of gas particles in the sprayer decreases and the gas pressure decreases.
8. **BIG IDEA** According to kinetic theory, the particles in a gas have insignificant volume, and the distance between particles in a gas is much greater than the distance between particles in a liquid or solid. Under pressure, the particles in a gas are forced closer together, resulting in a smaller overall volume.



CHEMISTRY & YOU: CAREERS

Atmospheric Chemist

Earth's atmosphere is a mixture of many gases, including oxygen, nitrogen, water vapor, carbon dioxide, methane, and ozone. Each one has an impact on life on Earth. The study of the chemical composition of the atmosphere is called atmospheric chemistry. Atmospheric chemists analyze the concentrations of atmospheric gases and determine how these gases chemically interact.

An important part of atmospheric research involves developing models that can predict the effects of fossil fuel emissions and other pollutants on air quality, climate, and the biosphere. Some atmospheric chemists study volcanic plumes, which are mixtures of hot gases and dust given off by volcanoes. Atmospheric chemistry is not limited to Earth's atmosphere. With the aid of telescopes, atmospheric chemists can study the composition of atmospheres of distant planets.

Atmospheric research is often a collaboration among scientists from different disciplines, including chemistry, physics, climatology, and oceanography. Atmospheric chemists typically have a bachelor's degree in chemistry or atmospheric science. Many also have a graduate degree in a specific field of research.

TOOLS AND TECHNOLOGY An atmospheric chemist adjusts a device used to analyze the motion and composition of air in the atmosphere.

AIR QUALITY Smog is a form of air pollution caused by tailpipe and smokestack emissions. The work of atmospheric chemists can help communities better understand how human activity impacts local air quality.

Take It Further

1. Infer What kinds of data do you think atmospheric chemists collect to study gases in the atmosphere?

2. Research a Problem Ozone (O_3) is one of many gases that atmospheric chemists study. Research the ozone layer and describe how atmospheric ozone levels have changed over time.

Differentiated Instruction

LPR LESS PROFICIENT READERS Have students identify and list unfamiliar words in the text. Assist students in using context clues and word roots to write a definition of each word. Check definitions for accuracy.

L1 STRUGGLING STUDENTS Review the chemical structures and formulas of methane and ozone. Explain how each substance is formed. Refer students to page R27 of the Elements Handbook for additional information on the ozone layer.

ELL ENGLISH LANGUAGE LEARNERS Clarify for students the roles of the Environmental Protection Agency (EPA) and the National Oceanographic and Atmospheric Administration (NOAA) in identifying, researching, and regulating greenhouse gas emissions. Ask students to share their knowledge of their native countries' government agencies responsible for these tasks, and use this information to draw parallels with the EPA and NOAA.

CHEMISTRY & YOU Point out to students that many weather reports now contain updates on air quality. Special alerts are issued when the amounts of certain pollutants that adversely affect human health are predicted to be above accepted maximum levels. Have students investigate the models used to predict these levels, and then have them write a summary of the pollutants monitored and the effects each has on health.

Connect to CIVICS

Point out to students that regulations to control greenhouse gas emissions begin in the houses of the United States Congress as bills, before being signed into law and inserted into the federal code. Assign students to teams acting as members of Congress who write a bill to regulate greenhouse gas emissions. Students should write the bill in the formal language and style used by Congress.

Answers

TAKE IT FURTHER

1. Sample answers: pressure, temperature, mass, concentration, altitude, geographic coordinates, time/date.
2. Due to ozone-depleting pollutants such as chlorofluorocarbons (CFCs), the amount of ozone in the ozone layer decreased sharply by the mid-1980s. Scientists estimate that it will take decades for the ozone layer to recover.

LESSON 14.2

Key Objectives

14.2.1 DESCRIBE the relationships among the temperature, pressure, and volume of a gas.

Engage

CHEMISTRY & YOU Have students study the photograph and read the text that opens the section. **Ask** What is the effect of heating a gas at constant pressure? *(The density of the gas decreases. As the density of the gas inside the balloon is lowered relative to the density of the gas outside the balloon, the balloon rises.)*

Activate Prior Knowledge

Review compressibility and the factors that affect gas pressure. **Ask** If the amount of gas in a cylinder remains constant, what happens to the volume if the gas is compressed? *(It decreases.)* What happens to the pressure? *(It increases.)* **Ask** How does increasing the temperature of a gas affect its pressure? *(The pressure increases.)* Its volume? *(The volume increases.)*

Explain that these basic relationships help form the basis of the gas laws.

IN ACADEMIC STANDARDS for SCIENCE

C.5.1 Use kinetic molecular theory to explain changes in gas volumes, pressure, moles, and temperature.

C.6.2 Distinguish between the concepts of temperature and heat flow in macroscopic and microscopic terms.

14.2 The Gas Laws

C.5.1 Kinetic molecular theory; **C.6.2** Distinguish between temperature and heat flow

CHEMISTRY & YOU

Q: *How do you fill up a hot air balloon?* A hot air balloon works on the principle that warm air is less dense than cooler air. To make a hot air balloon rise, the pilot heats the air inside the balloon. To make the balloon descend, the pilot releases hot air through a vent in the top of the balloon. In this section, you'll study the laws that allow you to predict gas behavior.

Key Question

How are the pressure, volume, and temperature of a gas related?

Vocabulary

- Boyle's law
- Charles's law
- Gay-Lussac's law
- combined gas law

Boyle's Law

How are the pressure and volume of a gas related?

Kinetic theory tells you that there is empty space between the particles in a gas. Imagine how an increase in pressure would affect the volume of a contained gas. **If the temperature is constant, as the pressure of a gas increases, the volume decreases.** In turn, as the pressure decreases, the volume increases. Robert Boyle was the first person to study this pressure-volume relationship in a systematic way. In 1662, Boyle proposed a law to describe the relationship. **Boyle's law** states that for a given mass of gas at constant temperature, the volume of the gas varies inversely with pressure.

Look at Figure 14.8. A gas with a volume of 1.0 L (V_1) is at a pressure of 100 kPa (P_1). As the volume increases to 2.0 L (V_2), the pressure decreases to 50 kPa (P_2). The product $P_1 \times V_1$ (100 kPa × 1.0 L = 100 kPa·L) is the same as the product $P_2 \times V_2$ (50 kPa × 2.0 L = 100 kPa·L). As the volume decreases to 0.5 L (V_3), the pressure increases to 200 kPa (P_3). Again, the product of the pressure and the volume equals 100 kPa·L.

Interpret Graphs

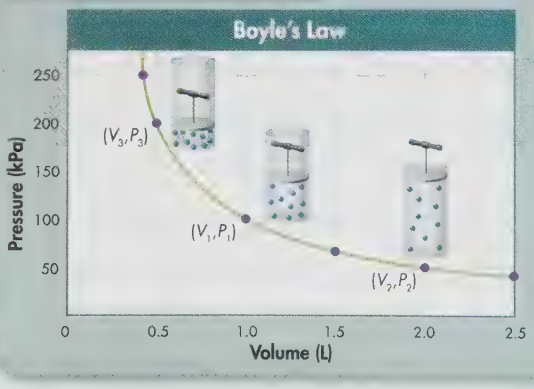

Figure 14.8 The pressure of a gas changes as the volume changes.
a. Read Graphs When the volume is 2.0 L, what is the pressure?
b. Predict What would the pressure be if the volume were increased to 3.0 L?
c. Draw Conclusions Based on the shape of the graph, describe the general pressure-volume relationship.

Focus on ELL

1 CONTENT AND LANGUAGE Ask students to state the key questions in their own words. Have pairs make and use flashcards with key equations. Have the pairs write the name of each gas law on one side and the equation on the other side. Allow students with limited English to use their native languages for support.

2 FRONTLOAD THE LESSON Encourage students to think about what happens when a partially filled balloon is squeezed. Ask them if they would notice a difference in the air pressure and volume. Direct them to the information in Chemistry & You.

3 COMPREHENSIBLE INPUT Explain the graphs of Boyle's and Charles's laws. Be sure to point out the different labels on the *x* and *y* axis of each graph and the letter for each variable. Discuss with students the meanings of *pressure, temperature,* and *volume.*

In an inverse relationship, the product of the two variable quantities is constant. So the product of pressure and volume at any two sets of pressure and volume conditions is always constant at a given temperature. The mathematical expression of Boyle's law is as follows.

$$P_1 \times V_1 = P_2 \times V_2$$

The graph of an inverse relationship is always a curve, as in Figure 14.8.

Sample Problem 14.1

Using Boyle's Law

A balloon contains 30.0 L of helium gas at 103 kPa. What is the volume of the helium when the balloon rises to an altitude where the pressure is only 25.0 kPa? (Assume that the temperature remains constant.)

1 Analyze **List the knowns and the unknown.**
Use Boyle's law ($P_1 \times V_1 = P_2 \times V_2$) to calculate the unknown volume (V_2).

KNOWNS	UNKNOWN
$P_1 = 103\ kPa$	$V_2 = ?\ L$
$V_1 = 30.0\ L$	
$P_2 = 25.0\ kPa$	

2 Calculate **Solve for the unknown.**

Start with Boyle's law.

$$P_1 \times V_1 = P_2 \times V_2$$

Isolate V_2 by dividing both sides by P_2:

$$\frac{P_1 \times V_1}{P_2} = \frac{P_2 \times V_2}{P_2}$$

Rearrange the equation to isolate V_2.

$$V_2 = \frac{P_1 \times V_1}{P_2}$$

Substitute the known values for P_1, V_1, and P_2 into the equation and solve.

$$V_2 = \frac{103\ kPa \times 30.0\ L}{25.0\ kPa}$$

$$= 1.24 \times 10^2\ L$$

3 Evaluate **Does the result make sense?** A decrease in pressure at constant temperature must correspond to a proportional increase in volume. The calculated result agrees with both kinetic theory and the pressure-volume relationship. The units have canceled correctly.

9. Nitrous oxide (N_2O) is used as an anesthetic. The pressure on 2.50 L of N_2O changes from 105 kPa to 40.5 kPa. If the temperature does not change, what will the new volume be?

10. A gas with a volume of 4.00 L at a pressure of 205 kPa is allowed to expand to a volume of 12.0 L. What is the pressure in the container if the temperature remains constant?

Solve Problem 10 by rearranging Boyle's law to isolate P_2.

Foundations for Math

CONVERSION FACTORS Before beginning to solve a problem, students should determine if the units of measurement in the problem match the units needed in the answer. If the units do not match, students should determine what conversion factors are needed. For temperature, the possible units are degrees Farenheit (°F), degrees Celsius (°C), and kelvins (K).

Look at the first part of Step 2 in **Sample Problem 14.2.** In this step, temperature is converted from degrees Celsius to kelvins by adding 273 to the values of T_1 and T_2.

Foundations for Reading

BUILD VOCABULARY Have students make a compare-contrast table for the gas laws. Have students include variables, constants, and the classification "direct or inverse."

READING STRATEGY Have students look at Figures 14.8 and 14.10 and use the graphs to write preliminary versions of Boyle's law and Charles's law.

Explain

Boyle's Law

APPLY CONCEPTS Have students consider what will happen when a helium-filled balloon is released into the sky. Assume the temperature remains constant. Remind students that as elevation increases, atmospheric pressure decreases. **Ask** If the balloon contains 30 L of gas at 100 kPa, what would its volume be at 25 kPa? *(120 L)*

Sample Practice Problem

The volume of a gas at 99.6 kPa and 24°C is 4.23 L. What volume will it occupy at 93.3 kPa and 24°C? *(4.52 L)*

Answers

INTERPRET GRAPHS

a. 50 kPa

b. about 33 kPa

c. As either pressure or volume increases, the other variable decreases.

9. $105\ kPa \times 2.50\ L = 40.5\ kPa \times V_2$
$V_2 = 105\ kPa \times 2.50\ L / 40.5\ kPa = 6.48\ L$

10. $205\ kPa \times 4.00\ L = P_2 \times 12.0\ L$
$P_2 = 205\ kPa \times 4.00\ L / 12.0\ L = 68.3\ kPa$

Extend

Teacher Demo

PURPOSE Students observe the effect that changing pressure has on the volume of a gas.

MATERIALS vacuum pump, bell jar, marshmallows

PROCEDURE Explain that marshmallows contain trapped air. Place several marshmallows in the bell jar, and then pull a vacuum in the jar. Ask students to explain why the marshmallows increase in size.

EXPECTED OUTCOME The removal of air surrounding the marshmallows reduces the pressure on them. Air trapped inside the marshmallows can expand to a greater volume.

Explain

Charles's Law

MAKE A CONNECTION Point out that when the pressure and amount of a gas are unchanged, the ratio of the volume of the gas to the absolute temperature of the gas is a constant. Mathematically, this constant can be expressed as $V_1/T_1 = V_2/T_2$ and is known as Charles's law.

USE VISUALS Direct students to the line on the graph in Figure 14.10. Point out the ΔV and ΔT labels in the graph. **Ask** What does the ratio $\Delta V/\Delta T$ represent? *(slope)*

APPLY CONCEPTS While solving Charles's law problems, students should remember that the new volume of a gas is equal to its original volume times a quotient. The value of the quotient indicates whether the gas is heated or cooled. If the gas is heated ($T_2 > T_1$), the new volume is greater because the gas expands. So, the quotient (T_2/T_1) has to be greater than 1. If the gas is cooled ($T_2 < T_1$), the new volume is smaller because the gas contracts. So, the quotient must be less than 1.

Figure 14.9 Cooling Balloons in Liquid Nitrogen
When the gas in a balloon is cooled at constant pressure, the volume of the gas decreases.
Predict *What would happen if you removed the balloons from the beaker and allowed them to warm back up to room temperature?*

Charles's Law

How are the temperature and volume of a gas related?

Figure 14.9 shows inflated balloons being dipped into a beaker of liquid nitrogen. For each balloon, the amount of air and the pressure are constant. As the air inside rapidly cools, the balloon shrinks. In fact, the gas volume decreases so much that all the cooled balloons can easily fit inside the beaker.

In 1787, the French physicist Jacques Charles studied the effect of temperature on the volume of a gas at constant pressure. When he graphed his data, Charles observed that a graph of gas volume versus temperature (in °C) is a straight line for any gas. **As the temperature of an enclosed gas increases, the volume increases if the pressure is constant.** When Charles extrapolated, or extended, the line to zero volume ($V = 0$), the line always intersected the temperature axis at −273.15°C. This value is equal to 0 on the Kelvin temperature scale. The observations that Charles made are summarized in Charles's law. **Charles's law** states that the volume of a fixed mass of gas is directly proportional to its Kelvin temperature if the pressure is kept constant. Look at the graph in Figure 14.10. When the temperature is 300 K, the volume is 1.0 L. When the temperature is 900 K, the volume is 3.0 L. In both cases, the ratio of V to T is 0.0033.

Interpret Graphs

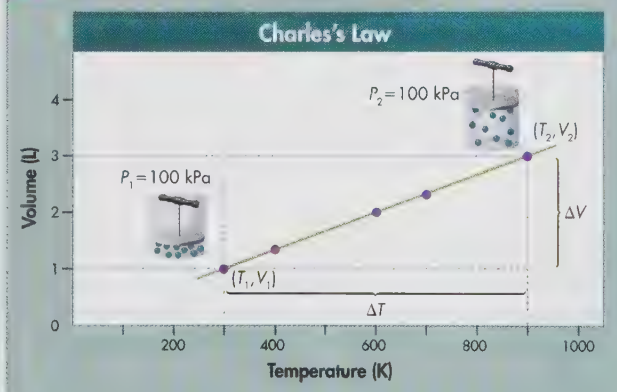

Figure 14.10 The graph shows how the volume changes as the temperature of a gas changes. View the Kinetic Art to see an online simulation of Charles's law.
a. Read Graphs In what unit is the temperature data expressed?
b. Draw Conclusions What happens to the volume as the temperature rises?
c. Predict If the temperature of a gas were 0 K, what would the volume of the gas be?

Hint: ΔV is the change in gas volume resulting from temperature change ΔT.

Differentiated Instruction

L3 GIFTED AND TALENTED Explain to students that Charles summarized his observations of the relationship between the volume and temperature of a gas in the following equation: $V = V_0(1 + aT)$ where V_0 is the volume of the gas at 0°C, T is its temperature expressed in °C, and a is a constant for all gases. Have students show that the numerical value of a is approximately 1/273.

ELL ENGLISH LANGUAGE LEARNERS Have English learners make a list of terms in this section that they don't understand. Pair them with other students who can use paraphrasing to explain the terms.

L1 SPECIAL NEEDS Consider having students work in pairs to solve the practice problems in this chapter. Match up students who have mastery of algebraic equation with students who need more practice solving for an unknown.

The ratio V_1/T_1 is equal to the ratio V_2/T_2. Because this ratio is constant at all conditions of temperature and volume, when the pressure is constant, you can write Charles's law as follows.

$$\frac{V_1}{T_1} = \frac{V_2}{T_2}$$

The ratio of the variables is always a constant in a direct relationship, and the graph is always a straight line. It is not a direct relationship if the temperatures are expressed in degrees Celsius. So when you solve gas law problems, the temperature must always be expressed in kelvins.

CHEMISTRY & YOU

Q: *A hot air balloon contains a propane burner onboard to heat the air inside the balloon. What happens to the volume of the balloon as the air is heated?*

SampleProblem 14.2

Using Charles's Law

A balloon inflated in a room at 24°C has a volume of 4.00 L. The balloon is then heated to a temperature of 58°C. What is the new volume if the pressure remains constant?

1 Analyze **List the knowns and the unknown.**
Use Charles's law ($V_1/T_1 = V_2/T_2$) to calculate the unknown volume (V_2).

KNOWNS	UNKNOWN
$V_1 = 4.00\ \text{L}$	$V_2 = ?\ \text{L}$
$T_1 = 24°\text{C}$	
$T_2 = 58°\text{C}$	

2 Calculate **Solve for the unknown.**

Because you will use a gas law, start by expressing the temperatures in kelvins.

$T_1 = 24°\text{C} + 273 = 297\ \text{K}$

$T_2 = 58°\text{C} + 273 = 331\ \text{K}$

Write the equation for Charles's law.

$$\frac{V_1}{T_1} = \frac{V_2}{T_2}$$

Isolate V_2 by multiplying both sides by T_2:

$$T_2 \times \frac{V_1}{T_1} = \frac{V_2}{T_2} \times T_2$$

Rearrange the equation to isolate V_2.

$$V_2 = \frac{V_1 \times T_2}{T_1}$$

Substitute the known values for T_1, V_1, and T_2 into the equation and solve.

$$V_2 = \frac{4.00\ \text{L} \times 331\ \text{K}}{297\ \text{K}} = 4.46\ \text{L}$$

3 Evaluate **Does the result make sense?** The volume increases as the temperature increases. This result agrees with both the kinetic theory and Charles's law.

11. If a sample of gas occupies 6.80 L at 325°C, what will its volume be at 25°C if the pressure does not change?

12. Exactly 5.00 L of air at −50.0°C is warmed to 100.0°C. What is the new volume if the pressure remains constant?

Foundations for Math

ISOLATING A VARIABLE The common transposition method is to do the same thing (mathematically) to both sides of an equation in order to get like terms together and isolate the variable, or unknown. In a shortcut method, students isolate the variable by moving like terms to one side of the equation. To maintain the equality of the two sides, there are two rules for the shortcut method: *When moving a term to the other side of the equal sign:* ***Rule 1*** Change the sign (for positive or negative values); ***Rule 2*** Invert the coefficient.

Point out that in **Sample Problem 14.2** Rule 1 is unnecessary because are there are no additions or subtractions in the equation for Charles's law. The only action taken was to invert the coefficient, $1/T_2$.

CHEMISTRY & YOU As the air inside a hot air balloon is heated, it expands at constant pressure. Charles's law states that the volume of a fixed amount of gas is directly proportional to its Kelvin temperature if the pressure is kept constant.

CRITICAL THINKING Explain to students that home cooks and food manufacturers rely on Charles's law to ensure a proper seal on glass jars with screw caps during the canning process. Lidded jars are placed in a water bath and heated for a specified time before being removed to cool. During the cooling process, the centers of the rubber-lined metal caps depress with an audible click as the vacuum seals form. Have students use Charles's law to explain why this process results in a vacuum seal. *(During heating, the air temperature in the jar increases, causing the air's volume to increase and forcing some molecules out of the jar. As the jar begins to cool, the temperature of the air decreases, causing its volume to decrease. This causes a seal to form between the lid and the lip of the glass jar. The click is caused by the vacuum pulling the center of the jar lid inward until it flexes.)*

Sample Practice Problem

The volume of a gas is 0.80 L at 101.3 kPa and 0°C.
Ask What volume will it occupy at 101.3 kPa and 24°C? *(0.87 L)*

Answers

FIGURE 14.9 The balloons would expand back to their original size.

INTERPRETING GRAPHS

a. kelvins
b. The volume increases
c. The volume would be 0.

11. $T_1 = 325\ \text{C} + 273 = 598\ \text{K}$
$T_2 = 25\ \text{C} + 273 = 298\ \text{K}$
$6.80\ \text{L}/598\ \text{K} = V_2/298\ \text{K}$
$V_2 = 298\ \text{K} \times 6.80\ \text{L}/598\ \text{K} = 3.39\ \text{L}$

12. $T_1 = -50.0\ \text{C} + 273 = 223\ \text{K}$
$T_2 = 100.0\ \text{C} + 273 = 373\ \text{K}$
$5.00\ \text{L}/223\ \text{K} = V_2/373\ \text{K}$
$V_2 = 373\ \text{K} \times 5.00\ \text{L}/223\ \text{K} = 8.36\ \text{L}$

Explain

Gay-Lussac's Law

MAKE A CONNECTION Use tire pressure to discuss the relationship between gas pressure and Kelvin temperature. **Ask** Why do auto tire manufacturers recommend checking for proper inflation before driving the car more than a mile? *(The tires get warm as the car moves, increasing the pressure inside the tires.)*

Explore

Student Activity

PURPOSE Students observe the relationship between the pressure and temperature of a gas.

MATERIALS 2 large vats, ice water, hot water, inflated bicycle tire

PROCEDURE Fill a large vat with ice water and a second vat with hot water. First, have students squeeze an inflated bicycle tire to assess its firmness. Next, immerse the tire in ice water and have them feel its firmness. Finally, immerse the tire in hot water and have them assess the firmness. Have the students describe the relationship between pressure and temperature at constant volume.

EXPECTED OUTCOME A direct relationship exists between pressure and temperature at a constant volume.

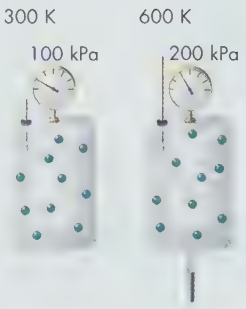

Figure 14.11 Gay-Lussac's Law When a gas is heated at constant volume, the pressure increases. **Interpret Diagrams** ***How can you tell from the drawings that there is a fixed amount of gas in the cylinders?***

Gay-Lussac's Law

How are the pressure and temperature of a gas related?

When tires are not inflated to the recommended pressure, fuel efficiency and traction decrease. Treads can wear down faster. Most importantly, improper inflation can lead to tire failure. A driver should not check tire pressure after driving a long distance because the air in a tire heats up during a drive. **As the temperature of an enclosed gas increases, the pressure increases if the volume is constant.**

Joseph Gay-Lussac (1778–1850), a French chemist, discovered the relationship between the pressure and temperature of a gas in 1802. The gas law that describes the relationship bears his name. **Gay-Lussac's law** states that the pressure of a gas is directly proportional to the Kelvin temperature if the volume remains constant. Look at Figure 14.11. When the temperature is 300 K, the pressure is 100 kPa. When the temperature is doubled to 600 K, the pressure doubles to 200 kPa. Because Gay-Lussac's law involves direct proportions, the ratios P_1/T_1 and P_2/T_2 are equal at constant volume. You can write Gay-Lussac's law as follows:

$$\frac{P_1}{T_1} = \frac{P_2}{T_2}$$

Gay-Lussac's law can be applied to reduce the time it takes to cook food. One cooking method involves placing food above a layer of water and heating the water. The water vapor, or steam, that is produced cooks the food. Steam that escapes from the pot is at a temperature of about 100°C when the pressure is near one atmosphere. In a pressure cooker, like the one shown in Figure 14.12, steam is trapped inside the cooker. The temperature of the steam reaches about 120°C. The food cooks faster at this higher temperature, but the pressure rises, which increases the risk of an explosion. A pressure cooker has a valve that allows some vapor to escape when the pressure exceeds the set value.

Figure 14.12 Pressure Cooker A pressure cooker is a gas-tight container in which pressurized steam is used to cook food. With the lid locked, the volume of steam and the number of water molecules are constant. So any increase in temperature causes an increase in pressure.

Differentiated Instruction

L3 GIFTED AND TALENTED Gases such as oxygen, nitrogen, helium, and hydrogen can be liquefied by lowering the temperature and increasing the pressure. But different gases must be cooled to different temperatures before they condense, no matter how high the pressure is raised. This temperature is called the critical temperature. Have students look up the critical temperatures for oxygen, nitrogen, helium, and hydrogen. **Ask** What do these temperatures indicate about the relative strengths of the intermolecular attractions in these gases? *(The lower the critical temperature, the lower the intermolecular attractive forces.)*

460 Chapter 14 • Lesson 2

Sample Problem 14.3

Using Gay-Lussac's Law

Aerosol cans carry labels warning not to incinerate (burn) the cans or store them above a certain temperature. This problem will show why it is dangerous to dispose of aerosol cans in a fire. The gas in a used aerosol can is at a pressure of 103 kPa at 25°C. If the can is thrown onto a fire, what will the pressure be when the temperature reaches 928°C?

1 Analyze **List the knowns and the unknown.** Use Gay-Lussac's law ($P_1/T_1 = P_2/T_2$) to calculate the unknown pressure (P_2). Remember, because this problem involves temperatures and a gas law, the temperatures must be expressed in kelvins.

KNOWNS	UNKNOWN
$P_1 = 103\ kPa$	$P_2 = ?\ kPa$
$T_1 = 25°C$	
$T_2 = 928°C$	

2 Calculate **Solve for the unknown.**

Start by converting the two known temperatures from degrees Celsius to kelvins.

$T_1 = 25°C + 273 = 298\ K$

$T_2 = 928°C + 273 = 1201\ K$

Write the equation for Gay-Lussac's law.

$$\frac{P_1}{T_1} = \frac{P_2}{T_2}$$

Isolate P_2 by multiplying both sides by T_2.

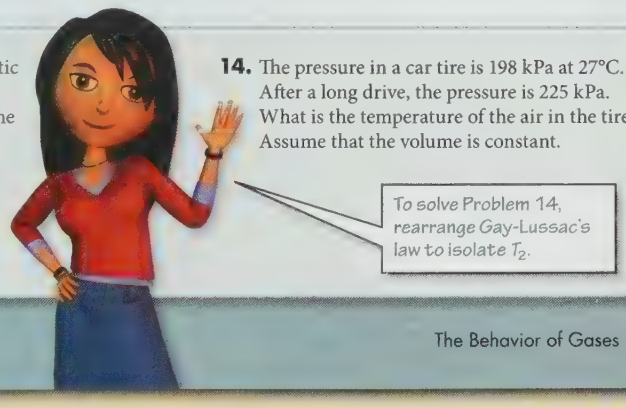
$$T_2 \times \frac{P_1}{T_1} = \frac{P_2}{T_2} \times T_2$$

Rearrange the equation to isolate P_2.

$$P_2 = \frac{P_1 \times T_2}{T_1}$$

Substitute the known values for P_1, T_2, and T_1 into the equation and solve.

$$P_2 = \frac{103\ kPa \times 1201\ K}{298\ K}$$



$$= 415\ kPa$$

$$= 4.15 \times 10^2\ kPa$$

3 Evaluate **Does the result make sense?** From the kinetic theory, one would expect the increase in temperature of a gas to produce an increase in pressure if the volume remains constant. The calculated value does show such an increase.

13. The pressure in a sealed plastic container is 108 kPa at 41°C. What is the pressure when the temperature drops to 22°C? Assume that the volume has not changed.

14. The pressure in a car tire is 198 kPa at 27°C. After a long drive, the pressure is 225 kPa. What is the temperature of the air in the tire? Assume that the volume is constant.

Foundations for Math

CHECK ANSWERS Whenever students have solved a problem, they should check the answer by substituting it back into the original equation. This lets them determine whether or not the value on each side of the equal sign is the same. At the same time, they should make sure that the units of the answer are appropriate for the unknown.

In **Sample Problem 14.3**, substituting 4.15×10^2 kPa for P_2 in the Gay-Lussac's law equation gives a value of 0.346 kPa/K. Since 103 kPa / 298 K = 0.346 kPa/K as well, the answer is correct. Note also that kPa is the appropriate unit of measurement for pressure.

Explain

START A CONVERSATION The direct relationship between pressure and temperature at constant volume can be expressed as $P_1/T_1 = P_2/T_2$. In Gay-Lussac's law problems, the new pressure of the gas is equal to its original pressure times a quotient. The value of the quotient indicates whether the gas is heated or cooled. If the gas is heated ($T_2 > T_1$), the new pressure is greater. So, the quotient (T_2/T_1) has to be greater than 1. If the gas is cooled ($T_2 < T_1$), the new pressure is less. So, the quotient must be less than 1.

Sample Practice Problem

A sample of nitrogen gas has a pressure of 6.58 kPa at 539 K. If the volume does not change, what will the pressure be at 211K? *(2.58 kPa)*

Answers

FIGURE 14.11 The number of particles in each container is the same.

13. $T_1 = 41\ C + 273 = 314\ K$
$T_2 = 22\ C + 273 = 295\ K$
$108\ kPa/314\ K = P_2/295\ K$
$P_2 = 295\ K \times 108\ kPa/314\ K = 101\ kPa$

14. $T_1 = 27\ C + 273 = 300\ K$
$198\ kPa/300\ K = 225\ kPa/T_2$
$T_2 = 225\ kPa \times 300\ K/198\ kPa = 341\ K\ (68\ C)$

Explain

The Combined Gas Law

USE VISUALS Write the equation for the combined gas law on the board. **Ask** What variable that is used to describe a gas is missing from this equation? *(n, the number of moles of gas)*

USE VISUALS Direct students to the weather balloon in Figure 14.13 on the following page. Remind students that in many situations, a sample of gas is simultaneously subjected to pressure and temperature changes that have opposite effects on volume. Consider a weather balloon rising through the atmosphere. The higher it rises, the colder the temperature and the lower the volume. At the same time, atmospheric pressure decreases, allowing the gas to expand. The combined gas law allows students to determine which variable has the greater effect on the volume.

Sample Practice Problem

The volume of a gas at 26°C and 75 kPa is 10.5 L. The pressure is increased to 116 kPa. What final temperature would be required to reduce the volume to 9.5 L? *(418 K, or 145°C)*

Extend

Connect to BIOLOGY

Ask students to inhale, hold, and exhale. Ask students to think about Boyle's law and how it applies to breathing. **Ask** How does Boyle's law explain why air enters your lungs when you inhale and leaves when you exhale? *(When you inhale, lung volume increases. Pressure decreases and air moves in. When you exhale, lung volume decreases. Pressure increases and air moves out.)* **Ask** Why do you think scuba divers are taught never to hold their breath as they ascend from deep water? *(As a diver ascends, pressure decreases. A decrease in pressure means an increase in volume. If a diver holds her breath while ascending, air volume in the lungs will increase.)*

The Combined Gas Law

How are the pressure, volume, and temperature of a gas related?

There is a single expression, called the **combined gas law,** that combines Boyle's law, Charles's law, and Gay-Lussac's law.

$$\frac{P_1 \times V_1}{T_1} = \frac{P_2 \times V_2}{T_2}$$

When only the amount of gas is constant, the combined gas law describes the relationship among pressure, volume, and temperature.

Sample Problem 14.4

Using the Combined Gas Law

The volume of a gas-filled balloon is 30.0 L at 313 K and 153 kPa pressure. What would the volume be at standard temperature and pressure (STP)?

KNOWNS	UNKNOWN
$V_1 = 30.0\ \text{L}$	$V_2 = ?\ \text{L}$
$T_1 = 313\ \text{K}$	
$P_1 = 153\ \text{kPa}$	
$T_2 = 273\ \text{K}$ (standard temperature)	
$P_2 = 101.3\ \text{kPa}$ (standard pressure)	

1 Analyze **List the knowns and the unknown.** Use the combined gas law ($P_1V_1/T_1 = P_2V_2/T_2$) to calculate the unknown volume (V_2).

2 Calculate **Solve for the unknown.**

State the combined gas law.

$$\frac{P_1 \times V_1}{T_1} = \frac{P_2 \times V_2}{T_2}$$

Isolate V_2 by multiplying both sides by T_2 and dividing both sides by P_2:

$$\frac{T_2}{P_2} \times \frac{P_1 \times V_1}{T_1} = \frac{P_2 \times V_2}{T_2} \times \frac{T_2}{P_2}$$

Rearrange the equation to isolate V_2.

$$V_2 = \frac{P_1 \times V_1 \times T_2}{P_2 \times T_1}$$

Substitute the known quantities into the equation and solve.

$$V_2 = \frac{153\ \text{kPa} \times 30.0\ \text{L} \times 273\ \text{K}}{101.3\ \text{kPa} \times 313\ \text{K}} = 39.5\ \text{L}$$

3 Evaluate **Does the result make sense?** A decrease in temperature and a decrease in pressure have opposite effects on the volume. To evaluate the increase in volume, multiply V_1 (30.0 L) by the ratio of P_1 to P_2 (1.51) and the ratio of T_2 to T_1 (0.872). The result is 39.5 L.

15. A gas at 155 kPa and 25°C has an initial volume of 1.00 L. The pressure of the gas increases to 605 kPa as the temperature is raised to 125°C. What is the new volume?

16. A 5.00-L air sample has a pressure of 107 kPa at a temperature of −50.0°C. If the temperature is raised to 102°C and the volume expands to 7.00 L, what will the new pressure be?

Foundations for Math

IDENTIFYING APPROPRIATE EQUATIONS An important step in solving gas law problems is determining which equation to use, since many gas laws use similar variables. Remind students that to identify the appropriate equation, they must first identify the known and unknown variables. Then they should ask themselves which equations use those variables. If more than one equation uses the same set of variables, they should reread the text of the question. They can then use the information in the question to identify the appropriate equation.

Look at **Sample Problem 14.4.** The question provides the known initial values for *P*, *V*, and *T* and asks students to calculate a final volume at STP. Since the combined gas law is the only equation that utilizes pressure, volume, and temperature, it is the appropriate equation for this calculation.

Weather balloons, like the one in Figure 14.13, carry a package of data-gathering instruments up into the atmosphere. At an altitude of about 27,000 meters, the balloon bursts. The combined gas law can help to explain this situation. Both outside temperature and pressure drop as the balloon rises. These changes have opposite effects on the volume of the weather balloon. A drop in temperature causes the volume of an enclosed gas to decrease. A drop in outside pressure causes the volume to increase. Given that the balloon bursts, the drop in pressure must affect the volume more than the drop in temperature does.

The combined gas law can also help you solve gas problems when only two variables are changing. It may seem challenging to remember four different expressions for the gas laws. But you actually only need to remember one expression—the combined gas law. You can derive the other laws from the combined gas law by holding one variable constant.

To illustrate, suppose you hold the temperature constant ($T_1 = T_2$). Rearrange the combined gas law so that the two temperature terms are on the same side of the equation. Because $T_1 = T_2$, the ratio of T_1 to T_2 is equal to one. Multiplying by 1 does not change a value in an equation. So when the temperature is constant, you can delete the temperature ratio from the rearranged combined gas law. What you are left with is the equation for Boyle's law.

$$P_1 \times V_1 = P_2 \times V_2 \times \frac{T_1}{T_2}$$

$$P_1 \times V_1 = P_2 \times V_2$$

A similar process yields Charles's law when pressure remains constant and Gay-Lussac's law when volume remains constant.

Figure 14.13 Weather Balloon
Meteorologists use weather balloons to gather data about Earth's atmosphere.
Infer *Why is helium more likely to be used in weather balloons than air?*

14.2 LessonCheck

17. Review How are the pressure and volume of a gas related at constant temperature?

18. Review If pressure is constant, how does a change in temperature affect the volume of a gas?

19. Review What is the relationship between the temperature and pressure of a contained gas at constant volume?

20. Describe In what situations is the combined gas law useful?

21. Define Write the mathematical equation for Boyle's law and explain the symbols.

22. Calculate A given mass of air has a volume of 6.00 L at 101 kPa. What volume will it occupy at 25.0 kPa if the temperature does not change?

23. Explain How can Charles's law be derived from the combined gas law?

24. Apply Concepts The volume of a weather balloon increases as the balloon rises in the atmosphere. Why doesn't the drop in temperature at higher altitudes cause the volume to decrease?

BIG IDEA KINETIC THEORY

25. Why do you think scientists cannot collect temperature and volume data for an enclosed gas at temperatures near absolute zero?

Lesson Check Answers

17. At constant temperature, volume decreases as pressure increases.

18. At constant pressure, volume increases as temperature increases.

19. At constant volume, pressure increases as temperature increases.

20. The combined gas law allows you to do calculations when the only constant is the amount of gas.

21. $P_1 \times V_1 = P_2 \times V_2$; P_1 = initial pressure; V_1 = initial volume; P_2 = final pressure; V_2 = final volume

22. 24.2 L

23. When the pressure is constant, $P_1 = P_2$, so the pressure terms cancel, leaving an equation for Charles's law.

24. The outside pressure decreases, causing a greater increase in the balloon's volume.

25. BIG IDEA As temperatures decrease toward absolute zero, particles in the gas slow down, and attractions between particles increase. A gas would liquefy and then solidify as it cooled to temperatures near absolute zero.

Evaluate

Informal Assessment

Sketch two balloons (one twice as large as the other) on the board. Label the smaller balloon V_1 and the other V_2, and indicate that $V_2 = 2V_1$. Copy the following table onto the chalkboard, listing only those values in boldface type. Have students complete the table.

T_1	T_2
(256 K)	**512 K**
40 C	*(353 C)*
(T_1)	**$2T_1$**
(–136 C)	**1 C**

Then have students complete the 14.2 Lesson Check.

Reteach

Write the combined gas law on the board. Remind students that the law is a combination of Boyle's, Charles's, and Gay-Lussac's laws. Have students examine the equation and rewrite the combined gas law, using a different color for the portion of the equation representing Boyle's law. Have them repeat this process for Charles's law and Gay-Lussac's law.

Answers

15. $T_1 = 25°C + 273 = 298$ K
$T_2 = 125°C + 273 = 398$ K
155 kPa × 1.00 L/298 K = 605 kPa × V_2/398 K
V_2 = 398 K × 155 kPa × 1.00 L/(298 K × 605 kPa) = 0.342 L

16. $T_1 = -50°C + 273 = 223$ K
$T_2 = 102°C + 273 = 375$ K
107 kPa × 5.00 L/223 K = P_2 × 7.00 L/375 K
P_2 = 375 K × 107 kPa × 5.00 L/(223 K × 7.00 L) = 1.29×10^2 kPa

FIGURE 14.13 Helium is less dense than air.

LESSON 14.3

Key Objectives

14.3.1 CALCULATE the amount of a contained gas when the pressure, volume, and temperature are specified.

14.3.2 DETERMINE conditions under which real gases are most likely to differ from ideal gases.

CHEMISTRY & YOU

Q: *How can you make fog indoors?* Carbon dioxide freezes at −78.5°C, which is much colder than the ice in your freezer. Solid carbon dioxide, or dry ice, can be used to make stage fog. Dry ice doesn't melt—it sublimes. As solid carbon dioxide changes to gas, water vapor in the air condenses and forms a white fog. Dry ice can exist because gases don't obey the assumptions of kinetic theory at all conditions. In this section, you will learn how real gases differ from the ideal gases on which the gas laws are based.

Key Questions

How can you calculate the amount of a contained gas when the pressure, volume, and temperature are specified?

Under what conditions are real gases most likely to differ from ideal gases?

Vocabulary

- ideal gas constant
- ideal gas law

Ideal Gas Law

How can you calculate the amount of a contained gas when the pressure, volume, and temperature are specified?

Up to this point, you have worked with three variables that describe a gas: pressure, volume, and temperature. There is a fourth variable still to be considered: the amount of gas in the system, expressed in terms of the number of moles.

Suppose you want to calculate the number of moles (n) of a gas in a fixed volume at a known temperature and pressure. By modifying the combined gas law, you can solve for n. First, you must recognize that the volume occupied by a gas at a specified temperature and pressure depends on the number of particles. The number of moles of gas is directly proportional to the number of particles. So moles must be directly proportional to volume as well. You can now introduce moles into the combined gas law by dividing each side of the equation by n.

$$\frac{P_1 \times V_1}{T_1 \times n_1} = \frac{P_2 \times V_2}{T_2 \times n_2}$$

This equation shows that $(P \times V)/(T \times n)$ is a constant. This constant holds for what are called ideal gases—gases that conform to the gas laws.

If you know the values for P, V, T, and n for one set of conditions, you can calculate a value for the constant. Recall that 1 mol of every gas occupies 22.4 L at STP (101.3 kPa and 273 K). You can use these values to find the value of the constant, which has the symbol R and is called the ideal gas constant. Insert the values of P, V, T, and n into $(P \times V)/(T \times n)$.

$$R = \frac{P \times V}{T \times n} = \frac{101.3\ \text{kPa} \times 22.4\ \text{L}}{273\ \text{K} \times 1\ \text{mol}} = 8.31\ (\text{L} \cdot \text{kPa})/(\text{K} \cdot \text{mol})$$

Focus on ELL

1 CONTENT AND LANGUAGE Direct students' attention to the vocabulary terms on page 464 and the heading on page 467. Clarify that the words *ideal, constant,* and *real* have both common and scientific meanings. Have pairs make and use flashcards with these terms. They should write a term on one side and the common and scientific definitions on the other. Have students practice writing sentences using each term in both its common and scientific context. Allow students with limited English to use their native languages for support.

2 FRONTLOAD THE LESSON Have students share their experiences with stage fog and/or dry ice sublimation, and ask them under what temperatures or seasons they encountered these events. Direct them to the information in Chemistry & You.

3 COMPREHENSIBLE INPUT Explain Figure 14.14. to students. Point out that scientists make use of the extremely cold temperature of liquid nitrogen to preserve biological samples.

The **ideal gas constant** (R) has the value 8.31 (L·kPa)/(K·mol). The gas law that includes all four variables—P, V, T, and n—is called the **ideal gas law.** It is usually written as follows.

$$P \times V = n \times R \times T \text{ or } PV = nRT$$

When the pressure, volume, and temperature of a contained gas are known, you can use the ideal gas law to calculate the number of moles of the gas. The amount of helium in a balloon, the amount of air in a scuba tank or a bicycle tire—each of these quantities can be calculated using the ideal gas law as long as you know the values for P, V, and T in each case.

Sample Problem 14.5

Using the Ideal Gas Law

At 34°C, the pressure inside a nitrogen-filled tennis ball with a volume of 0.148 L is 212 kPa. How many moles of nitrogen gas are in the tennis ball?

1 Analyze **List the knowns and the unknown.**
Use the ideal gas law ($P \times V = n \times R \times T$) to calculate the number of moles (n).

KNOWNS
$P = 212$ kPa
$V = 0.148$ L
$T = 34°C$
$R = 8.31$ (L·kPa) / (K·mol)

UNKNOWN
$n = ?$ mol N_2

2 Calculate **Solve for the unknown.**

Convert degrees Celsius to kelvins

$$T = 34°C + 273 = 307 \text{ K}$$

Write the ideal gas law

$$P \times V = n \times R \times T$$

Isolate n by dividing both sides by $(R \times T)$:

$$\frac{P \times V}{R \times T} = \frac{n \times \cancel{R} \times \cancel{T}}{\cancel{R} \times \cancel{T}}$$

Rearrange the equation to isolate n

$$n = \frac{P \times V}{R \times T}$$

Substitute the known values for P, V, R, and T into the equation and solve.

$$n = \frac{P \times V}{R \times T} = \frac{212 \text{ kPa} \times 0.148 \text{ L}}{8.31 \text{ (L·kPa) / (K·mol)} \times 307 \text{ K}} = 0.0123 \text{ mol } N_2$$

$$= 1.23 \times 10^{-2} \text{ mol } N_2$$

3 Evaluate **Does the result make sense?** A tennis ball has a small volume and is not under great pressure. It is reasonable that the ball contains a small amount of nitrogen.

26. When the temperature of a rigid hollow sphere containing 685 L of helium gas is held to 621 K, the pressure of the gas is 1.89×10^3 kPa. How many moles of helium does the sphere contain?

27. What pressure will be exerted by 0.450 mol of a gas at 25°C if it is contained in a 0.650-L vessel?

Foundations for Math

SCIENTIFIC NOTATION Gas law calculations often result in very large or very small numbers. Converting these numbers to scientific notation makes them more manageable and easier to read. Before converting to scientific notation, students should identify the direction in which the decimal point needs to move. This determines the sign of the exponent. The direction of decimal point movement is determined by whether the number is greater than or less than one.

In **Sample Problem 14.5**, the answer is less than one, so the decimal point needs to move to the right in order to convert the number to scientific notation. Moving the decimal point to the right gives a negative exponent. In the sample problem, the decimal point moves two places to the right, so the exponent for 10 will be -2.

Explain

Ideal Gas Law

USE VISUALS Sketch two containers with identical volumes on the board. Tell students one container is filled with neon gas and the other with helium at the same temperature and pressure. Ask students to use the ideal gas law to find the equation for the number of moles in each container. Students should determine that $n_{He} = n_{Ne}$.

START A CONVERSATION Explain that Avogadro's hypothesis makes it possible to relate the molar quantity of a gas to its temperature, volume, and pressure. The hypothesis assumes that as long as the particles are not tightly packed, equal volumes of gases at the same temperature and pressure contain equal numbers of particles. Emphasize that Avogadro's hypothesis works only for gases because a large portion of their volume is empty space. At low pressure, the volumes of individual molecules are negligible compared to the volume of the container holding the gas. The volume of a gas depends on the number of particles present, not their size. **Ask** How would you determine the mass of the helium in a balloon, at STP, without making any mass measurements? *(According to Avogadro's hypothesis, one mole of a gas has a volume of 22.4 L at STP. Calculate the volume of the helium in the balloon, in liters at STP. Then, convert from liters to moles. To find the mass, multiply the number of moles by the molar mass of He.)*

Sample Practice Problem

A helium-filled balloon contains 0.16 mol He at 101 kPa and a temperature of 23°C. What is the volume of the gas in the balloon? *(3.9 L)*

Answers

26. 2.51×10^2 mol
27. 1.71×10^3 kPa

Explain

Sample Practice Problems

A. When the temperature of a rigid cylinder containing 235 L of argon gas is held to 365 K, the pressure of the gas is 768 kPa. How many moles of argon does the cylinder contain? *(59.5 mol Ar)*

B. What is the volume of a vessel that contains 0.500 mol of a gas, if the gas exerts 3.75×10^3 kPa of pressure at 25°C? *(0.330 L)*

Sample Problem 14.6

Using the Ideal Gas Law

A deep underground cavern contains 2.24×10^6 L of methane gas (CH_4) at a pressure of 1.50×10^3 kPa and a temperature of 315 K. How many kilograms of CH_4 does the cavern contain?

1 Analyze **List the knowns and the unknown.**
Calculate the number of moles (n) using the ideal gas law. Use the molar mass of methane to convert moles to grams. Then convert grams to kilograms.

KNOWNS	UNKNOWN
$P = 1.50 \times 10^3$ kPa	$m = ?$ kg CH_4
$V = 2.24 \times 10^6$ L	
$T = 315$ K	
$R = 8.31$ (L·kPa) / (K·mol)	
molar mass$_{CH_4} = 16.0$ g	

2 Calculate **Solve for the unknown.**

Start from the ideal gas law:

$$P \times V = n \times R \times T$$

Rearrange the equation to isolate n:

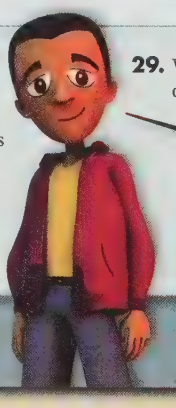
$$n = \frac{P \times V}{R \times T}$$

Substitute the known quantities into the equation to find the number of moles of methane:

$$n = \frac{(1.50 \times 10^3 \text{ kPa}) \times (2.24 \times 10^6 \text{ L})}{8.31 \frac{\text{L} \cdot \text{kPa}}{\text{K} \cdot \text{mol}} \times 315 \text{ K}} = 1.28 \times 10^6 \text{ mol } CH_4$$

Do a molar mass conversion:

$$1.28 \times 10^6 \text{ mol } CH_4 \times \frac{16.0 \text{ g } CH_4}{1 \text{ mol } CH_4} = 20.5 \times 10^6 \text{ g } CH_4$$



$$= 2.05 \times 10^7 \text{ g } CH_4$$

Convert from grams to kilograms:

$$2.05 \times 10^7 \text{ g } CH_4 \times \frac{1 \text{ kg}}{10^3 \text{ g}} = 2.05 \times 10^4 \text{ kg } CH_4$$

3 Evaluate **Does the result make sense?** Although the methane is compressed, its volume is still very large. So it is reasonable that the cavern contains a large mass of methane.

28. A child's lungs can hold 2.20 L. How many grams of air do her lungs hold at a pressure of 102 kPa and a body temperature of 37°C? Use a molar mass of 29 g for air, which is about 20% O_2 (32 g/mol) and 80% N_2 (28 g/mol).

29. What volume will 12.0 g of oxygen gas (O_2) occupy at 25°C and a pressure of 52.7 kPa?

In Problems 28 and 29, make sure to express the temperature in kelvins before substituting for T in the ideal gas law equation.

Foundations for Math

RECIPROCALS Before dividing fractions, you have to define *reciprocal*. Two fractions are reciprocals of each other if their product is 1. For example, $\frac{2}{3}$ and $\frac{3}{2}$ are reciprocals since $\frac{2}{3} \times \frac{3}{2} = 1$.

This mathematical property holds true when converting units. Look at the third part of Step 2 in **Sample Problem 14.6**. When all the units are canceled, you are left with 1/1/mol. Keeping reciprocals in mind, you know that 1/1/mol is the same as 1 x mol/1, so the units are moles.

466 Chapter 14 • Lesson 3

Ideal Gases and Real Gases

Under what conditions are real gases most likely to differ from ideal gases?

An ideal gas is one that follows the gas laws at all conditions of pressure and temperature. Such a gas would have to conform precisely to the assumptions of kinetic theory. Its particles could have no volume, and there could be no attraction between particles in the gas. As you probably suspect, there is no gas for which these assumptions are true. So an ideal gas does not exist. Nevertheless, at many conditions of temperature and pressure, a real gas behaves very much like an ideal gas.

The particles in a real gas do have volume, and there are attractions between the particles. Because of these attractions, a gas can condense, or even solidify, when it is compressed or cooled. For example, if water vapor is cooled below 100°C at standard atmospheric pressure, it condenses to a liquid. The behavior of other real gases is similar, although lower temperatures and greater pressures may be required. Such conditions are required to produce the liquid nitrogen in Figure 14.14. **Real gases differ most from an ideal gas at low temperatures and high pressures.**

Figure 14.14 Liquid Nitrogen
A lab technician places a cell sample into an insulated tank containing liquid nitrogen. Nitrogen boils at −196°C.

QuickLab

Carbon Dioxide From Antacid Tablets

Purpose To measure the amount of carbon dioxide gas given off when antacid tablets dissolve in water

Materials

- 6 effervescent antacid tablets
- 3 rubber balloons (spherical)
- plastic medicine dropper
- water
- clock or watch
- metric tape measure
- graph paper
- water
- pressure sensor (optional)

Procedure

1. Break six antacid tablets into small pieces. Keep the pieces from each tablet in a separate pile. Put the pieces from one tablet into the first balloon. Put the pieces from two tablets into a second balloon. Put the pieces from three tablets into a third balloon. **CAUTION** *If you are allergic to latex, do not handle the balloons.*
2. After you use the medicine dropper to squirt about 5 mL of cold water into each balloon, immediately tie off each balloon.
3. Shake the balloons to mix the contents. Allow the contents to warm to room temperature.
4. Measure and record the circumference of each balloon several times during the next 20 minutes.
5. Use the maximum circumference of each balloon to calculate its volume. (*Hint:* For the volume of a sphere, use $V = \frac{4}{3}\pi r^3$ and $r = \text{circumference}/2\pi$.)

Analyze and Conclude

1. **Graph** Make a graph of volume versus number of tablets. Use your graph to describe the relationship between the number of tablets used and the volume of the balloon.
2. **Calculate** Assume that the balloon is filled with carbon dioxide gas at 20°C and standard pressure. Calculate the mass and the number of moles of CO_2 in each balloon at maximum inflation.
3. **Analyze Data** If a typical antacid tablet contains 2.0 g of sodium hydrogen carbonate, how many moles of CO_2 should one tablet yield? Compare this theoretical value with your results.

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups to complete the lab. Make sure each group has ELLs of varied language proficiencies so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Allow students to use drawings, single words, or short phrases. Have them copy the written work of more proficient students for future reference.

INTERMEDIATE: LOW/HIGH Have students draft sentences to answer the questions that require writing.

ADVANCED: LOW/HIGH Have students assist and/or edit the work of classmates with lower language proficiency.

Explain

Ideal Gases and Real Gases

APPLY CONCEPTS Have students apply the ideal gas law to a sample of gas in a balloon. Ask them to explain why in a balloon n and R are constants and P, V, and T are variables.

Explore

QuickLab

PURPOSE After completing this activity, students will be able to measure the amount of carbon dioxide gas given off when antacid tablets dissolve in water.

SKILLS FOCUS observing, calculating, measuring

PREP TIME 10 minutes

CLASS TIME 40 minutes

SAFETY If you use latex balloons, check to see if any students are allergic to latex.

EXPECTED OUTCOME The volumes of CO_2 produced will reflect the amount of antacid each balloon contains.

ANALYZE AND CONCLUDE

1. The volume of the balloon is directly proportional to the number of tablets.
2. Answers will vary, but the masses and numbers of moles should be in ratios of 1:2:3 for the three balloons.
3. Possible answer: 2.0 g of $NaHCO_3$ (molar mass = 84.01 g) should yield about 1.2×10^{-2} mol of CO_2.

EXTENSION Have students use a similar procedure to compare different brands of effervescent antacids instead of different amounts of the same antacid.

Answers

28. 2.5 g air

29. 17.6 L

Explain

INTERPRET GRAPHS Investigate how real gases are different from ideal gases. For an ideal gas, by definition $PV = nRT$, and the ratio of PV/nRT is 1. **Ask** When the volume of a gas is greater than expected, what is the value of the ratio of PV to nRT? *(PV to nRT tends to be greater than 1.)* **Ask** When the volume is less than expected, what is the value of the ratio of PV to nRT? *(PV to nRT tends to be less than 1.)*

CHEMISTRY & YOU Sublimation (when the solid carbon dioxide changes to gas) and condensation (when water vapor in the air changes to liquid).

Evaluate

Informal Assessment

Have students use Boyle's law to explain how a plunger opens a clogged drain. *(As the plunger is pushed down, the volume of air in the plunger decreases and the pressure increases. Increased pressure is transferred throughout any water in the drain, and this pressure is applied to the clog.)* Then have students complete the 14.3 Lesson Check.

Reteach

If students are having trouble understanding Boyle's law, have them illustrate Boyle's law using dots to represent gas particles. They should begin with an illustration that shows the particles in a starting condition. The other illustrations should show the particles' positions after changes in pressure.

Interpret Graphs

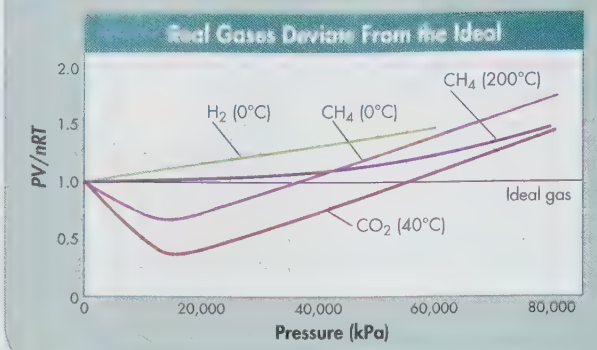


Figure 14.15 This graph shows how real gases deviate from the ideal gas law at high pressures.

a. Read Graphs What are the values of (PV/nRT) for an ideal gas at 20,000 and 60,000 kPa?

b. Identify What variable is responsible for the differences between the two methane (CH_4) curves?

c. Make Generalizations How does an increase in pressure affect the value of (PV/nRT) for real gases?

CHEMISTRY & YOU

Q: *Certain types of fog machines use dry ice and water to create stage fog. Chunks of dry ice are added to hot water, which causes the dry ice to sublime. The cold carbon dioxide gas causes water vapor in the surrounding air to condense into small droplets, resulting in a smoky fog. What phase changes occur when stage fog is made?*

Figure 14.15 shows how the value of the ratio (PV/nRT) changes as pressure increases. For an ideal gas, the result is a horizontal line because the ratio is always equal to 1. For real gases at high pressure, the ratio may deviate, or depart, from the ideal. When the ratio is greater than 1, the curve rises above the ideal gas line. When the ratio is less than 1, the curve drops below the line. The deviations can be explained by two factors. As attractive forces reduce the distance between particles, a gas occupies less volume than expected, causing the ratio to be less than 1. But the actual volume of the molecules causes the ratio to be greater than 1.

In portions of the curves below the line, intermolecular attractions dominate. In portions of the curves above the line, molecular volume dominates. Look at the curves for methane (CH_4) at 0°C and at 200°C. At 200°C, the molecules have more kinetic energy to overcome intermolecular attractions. So the curve for CH_4 at 200°C never drops below the line.

14.3 Lesson Check

30. Review How can you determine the number of moles of a contained gas when the pressure, volume, and temperature are known values?

31. Identify Under what conditions do real gases deviate most from ideal behavior?

32. Calculate Determine the volume occupied by 0.582 mol of a gas at 15°C if the pressure is 81.8 kPa.

33. Calculate You fill a rigid steel cylinder that has a volume of 20.0 L with nitrogen gas to a final pressure of 2.00×10^4 kPa at 28°C. How many kilograms of N_2 does the cylinder contain?

34. Compare What is the difference between a real gas and an ideal gas?

35. Analyze Data At standard pressure, ammonia condenses at −33.3°C but nitrogen does not condense until −195.79°C. Use what you know about bond polarity to explain this difference.

BIG IDEA KINETIC THEORY

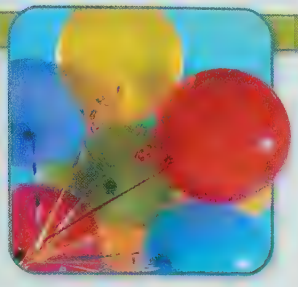
36. Use the kinetic theory of gases to explain this statement: No gas exhibits ideal behavior at all temperatures and pressures.

Lesson Check Answers

30. by using the equation for the ideal gas law $(PV = nRT)$

31. Real gases deviate from ideal behavior at low temperatures and high pressures.

32. 17.0 L



33. 4.48 kg

34. An ideal gas obeys the assumptions of kinetic theory. A real gas deviates from ideal behavior except within a small range of conditions.

35. The nitrogen molecule is nonpolar and the ammonia molecule is polar. So there are stronger intermolecular attractions in ammonia.

36. BIG IDEA In real gases, there are attractions between molecules, and the molecules have volume. At low temperatures, attractions between molecules pull them together and reduce the volume. At high pressures, the volume occupied by the molecules is a significant part of the total volume.

14.4 Gases: Mixtures and Movements

CHEMISTRY & YOU

Q: *Why do balloons filled with helium deflate faster than balloons filled with air?* You have probably seen party balloons inflated with air or helium. The surface of a latex balloon has tiny pores through which gas particles can pass, causing the balloon to deflate over time. The rate at which the balloon deflates depends on the gas it contains.

Key Questions

How is the total pressure of a gas mixture related to the partial pressures of the component gases?

How does the molar mass of a gas affect the rate at which the gas diffuses or effuses?

Vocabulary

- partial pressure
- Dalton's law of partial pressures
- diffusion • effusion
- Graham's law of effusion

Dalton's Law

How is the total pressure of a gas mixture related to the partial pressures of the component gases?

Gas pressure results from collisions of particles in a gas with an object. If the number of particles increases in a given volume, more collisions occur. If the average kinetic energy of the particles increases, more collisions occur. In both cases, the pressure increases. Gas pressure depends only on the number of particles in a given volume and on their average kinetic energy. Particles in a mixture of gases at the same temperature have the same average kinetic energy. So the kind of particle is not important.

Table 14.1 shows the composition of dry air, or air that does not contain any water vapor. The contribution each gas in a mixture makes to the total pressure is called the **partial pressure** exerted by that gas. In dry air, the partial pressure of nitrogen is 79.11 kPa. **In a mixture of gases, the total pressure is the sum of the partial pressures of the gases.**

Interpret Data

Composition of Dry Air

Component	Volume (%)	Partial pressure (kPa)
Nitrogen	78.08	79.11
Oxygen	20.95	21.22
Carbon dioxide	0.04	0.04
Argon and others	0.93	0.95
Total	**100.00**	**101.32**

Table 14.1 The total pressure of dry air is the sum of the partial pressures of its component gases.

a. Read Tables What is the partial pressure of oxygen in dry air?

b. Predict As altitude increases, atmospheric pressure decreases. What do you think happens to the partial pressure of oxygen in the air as altitude increases?

Focus on ELL

1 CONTENT AND LANGUAGE Ask students to restate the key questions in their own words. Have pairs make and use flashcards with key vocabulary. They should write the term on one side and a definition, visual, and sentence with the term on the other. Allow students with limited English to use their native languages for support.

2 FRONTLOAD THE LESSON Have students discuss their experiences with helium balloons, and ask if they know why these balloons float. Direct them to the information in Chemistry & You.

3 COMPREHENSIBLE INPUT Explain Figure 14.18, restating information in its captions as needed. Model solving Sample Problem 14.7 by explaining your thought process aloud while writing on the board.

Key Objectives

14.4.1 RELATE the total pressure of a mixture of gases to the partial pressures of the component gases.

14.4.2 EXPLAIN how the molar mass of a gas affects the rate at which the gas diffuses and effuses.

Additional Resources

PearsonChem.com

Engage

CHEMISTRY & YOU Have students study the photograph and read the opening text. Ask students to predict an answer, and write it on the board.

Build Background

Have students speculate on how smelling salts work. Explain that most smelling salts contain ammonia (NH_3). If possible bring smelling salts to class and demonstrate. *(Ammonia gas diffuses into the air and irritates the membranes of the nose, triggering an inhalation reflex.)*

Foundations for Reading

BUILD VOCABULARY Students may have trouble with the scientific definitions of *effusion* and *diffusion* because the common meanings often overlap. Ask students what strategy they will use to help them remember that particles move apart during *diffusion* but through a tiny hole during *effusion*.

Answers

INTERPRET GRAPHS

a. 1.0 in both cases

b. temperature

c. The ratio increases.

INTERPRET DATA

a. 21.22 kPa

b. The partial pressure decreases.

Explain

Dalton's Law

START A CONVERSATION Assist students in understanding that the relative partial pressure exerted by a gas in a mixture of gases does not vary with temperature, pressure, or volume of the mixture. The ratio of n_1/n (the relative amount of the gas in the mixture) remains the same. Because the value of n_1/n remains constant, the relative partial pressure (P_1/P) exerted by the gas remains the same.

Explore

Student Activity

PURPOSE Students make a model that is analogous to Dalton's law.

MATERIALS balance, 4 marbles, 2 buttons, 3 pennies, 4 nickels

PROCEDURE Have students find the total mass of the marbles and record it in a data table. Have them repeat this process for the buttons and the pennies. Then, have them add the masses of all the marbles, buttons, and pennies together and find the overall mass. **Ask** How does the total mass of the items compare to the sum of the masses of the individual items? *(The sum of the individual masses should equal the total mass.)* **Ask** If the nickels are added to the mixture, how could you find the mass of the nickels? *(The mass of the nickels could be calculated by finding a new total mass and subtracting from it the masses of the marbles, the buttons, and the pennies.)*

EXPECTED OUTCOME Students should recognize that mass is being used to represent pressure and that the contribution of each type of item to the total mass is independent of the other types of items in the mixture.

See Dalton's Law animated online.

The data in Table 14.1 illustrate a law proposed by the chemist John Dalton. **Dalton's law of partial pressures** states that, at constant volume and temperature, the total pressure exerted by a mixture of gases is equal to the sum of the partial pressures of the component gases. You can express Dalton's law mathematically as follows:

$$P_{total} = P_1 + P_2 + P_3 + \ldots$$

Dalton's law holds true because each component gas exerts its own pressure independent of the pressure exerted by the other gases. Look at Figure 14.16a. The container is filled with heliox, a helium-oxygen gas mixture used in deep-sea scuba diving. The helium component of this mixture is shown in Figure 14.16b at the same volume and temperature. The oxygen component is shown in Figure 14.16c, also at the same volume and temperature. Each gas in the mixture exerts the pressure it exerted before the gases were mixed to make heliox. So the pressure in the container of heliox (500 kPa) is the sum of the pressures in the containers of helium and oxygen (400 kPa + 100 kPa).

If the percent composition of a mixture of gases does not change, the fraction of the pressure exerted by a gas does not change as the total pressure changes. This fact is important for people who must operate at high altitudes. For example, at the top of Mount Everest, the total atmospheric pressure is 33.73 kPa. This pressure is about one third of its value at sea level. The partial pressure of oxygen is also reduced by one third, to 7.06 kPa. But in order to support respiration in humans, the partial pressure of oxygen must be 10.67 kPa or higher. So climbers of Mount Everest need an oxygen mask and a cylinder of compressed oxygen to survive the ascent.

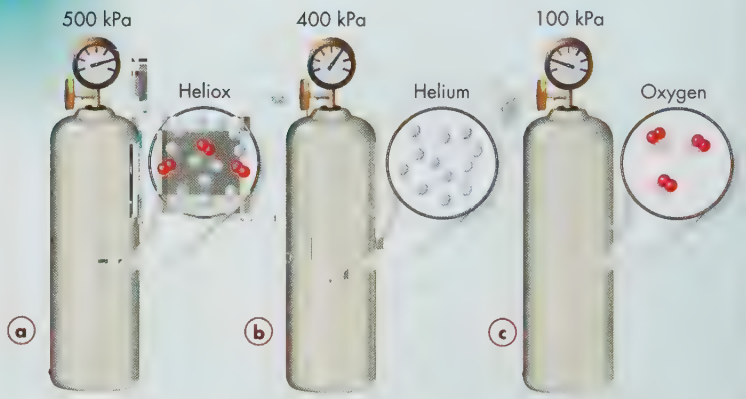

Figure 14.16 Dalton's Law Heliox is a mixture of helium and oxygen gas. The pressure exerted by the helium in the mixture is independent of the pressure exerted by the oxygen. **Compare** ***How does the ratio of helium atoms to oxygen molecules in heliox compare to the ratio of the partial pressures?***

Professional Development Note

Decompression Sickness

The invention of compressed air in the 1840s allowed people to work underwater, with one major drawback. Decompression sickness was initially called caisson disease because workers constructing the Brooklyn Bridge worked in watertight containers called caissons. The pressure of the air in the caissons needed to be greater than atmospheric pressure to withstand the pressure of the surrounding water. The disease the workers experienced was also called "the bends." In 1878, Paul Bert stated that workers could avoid the bends if they ascended gradually to the surface. Bert referred to the work of Robert Boyle. In 1667, Boyle observed a bubble form in the eye of a viper that was placed in a compressed atmosphere and then removed. (Boyle reported that the viper appeared distressed by the experience.)

Sample Problem 14.7

Using Dalton's Law of Partial Pressures

Air contains oxygen, nitrogen, carbon dioxide, and trace amounts of other gases. What is the partial pressure of oxygen (P_{O_2}) at 101.30 kPa of total pressure if the partial pressures of nitrogen, carbon dioxide, and other gases are 79.10 kPa, 0.040 kPa, and 0.94 kPa, respectively?

1 Analyze **List the knowns and the unknown.**
Use the equation for Dalton's law of partial pressures ($P_{total} = P_{O_2} + P_{N_2} + P_{CO_2} + P_{others}$) to calculate the unknown value (P_{O_2}).

KNOWNS
$P_{N_2} = 79.10\ kPa$
$P_{CO_2} = 0.040\ kPa$
$P_{others} = 0.94\ kPa$
$P_{total} = 101.30\ kPa$

UNKNOWN
$P_{O_2} = ?\ kPa$

2 Calculate **Solve for the unknown.**

Start with Dalton's law of partial pressures.

$$P_{total} = P_{O_2} + P_{N_2} + P_{CO_2} + P_{others}$$

Isolate P_{O_2} by subtracting the sum $(P_{N_2} + P_{CO_2} + P_{others})$ from both sides.

Rearrange Dalton's law to isolate P_{O_2}.

$$P_{O_2} = P_{total} - (P_{N_2} + P_{CO_2} + P_{others})$$

Substitute the values for P_{total} and the known partial pressures.

$$= 101.30\ kPa - (79.10\ kPa + 0.040\ kPa + 0.94\ kPa)$$

$$= 21.22\ kPa$$

3 Evaluate **Does this result make sense?** The partial pressure of oxygen must be smaller than that of nitrogen because P_{total} is only 101.30 kPa. The other partial pressures are small, so the calculated answer of 21.22 kPa seems reasonable.

37. A gas mixture containing oxygen, nitrogen, and carbon dioxide has a total pressure of 32.9 kPa. If $P_{O_2} = 6.6$ kPa and $P_{N_2} = 23.0$ kPa, what is P_{CO_2}?

38. Determine the total pressure of a gas mixture that contains oxygen, nitrogen, and helium. The partial pressures are $P_{O_2} = 20.0$ kPa, $P_{N_2} = 46.7$ kPa, and $P_{He} = 26.7$ kPa.

In Problem 38, the unknown is P_{total}, so you can solve without having to rearrange Dalton's law.

Foundations for Math

ISOLATING A VARIABLE Remind students that there are two shortcut methods for maintaining the equality of the two sides of an equation when isolating a variable: ***Rule 1*** Change the sign (for positive or negative values); ***Rule 2*** Invert the coefficient.

Point out that in **Sample Problem 14.7**, Rule 1 is used to isolate P_{O_2}. The sign change is accomplished by subtracting the sum of partial pressures of the remaining gases in air from both sides of the equation to yield the second step of the equation:

$$P_{total} - (P_{N_2} + P_{CO_2} + P_{others}) = P_{O_2} + P_{N_2} + P_{CO_2} + P_{others} - (P_{N_2} + P_{CO_2} + P_{others})$$

Students should recognize that subtracting the sum of the partial pressures is the same as subtracting each partial pressure from both sides separately.

Explain

MAKE A CONNECTION Explain to students that Dalton's law of partial pressures has important applications for pilots and mountain climbers. People who work at high altitudes must have a source of supplementary oxygen to ensure that the pressure of oxygen in their blood is high enough for them to survive. Adding oxygen to a mixture results in a higher percentage of oxygen and thus a higher partial pressure. Oxygen masks, for example, provide a higher partial pressure of oxygen. Ask students for examples of where an oxygen mask is used. *(in hospitals where people have trouble breathing; at fire scenes where people have inhaled smoke; at sporting events where athletes cannot get enough oxygen)*

USE AN ANALOGY Use the following analogy to help students with the concept of partial pressures. If possible, try to bring a bag of chocolates to demonstrate.

You are given a 2.00-kg bag of chocolates and in the bag you find there are four kinds of chocolates. You can separate each kind into a pile and find the mass of each pile. To find the percentage mass of each kind of chocolate, you divide each partial mass by the total and multiply by 100.

Kind of chocolate	Mass	Percentage of total
red	0.85 kg	42.5%
yellow	0.32 kg	16%
green	0.66 kg	33%
brown	0.17 kg	8.5%
Total	**2.00 kg**	**100%**

Sample Practice Problem

In a gas mixture of H_2, He, and Ar the total pressure is 101.3 kPa. The partial pressure of Ar is 50.7kPa, and the partial pressure of He is 10.1 kPa. What is the pressure of H_2? *(40.5 kPa)*

Answers

FIGURE 14.16 The ratios are equal.

37. 32.9 kPa − 6.6 kPa − 23.0 kPa = 3.3 kPa

38. 20.0 kPa + 46.7 kPa + 26.7 kPa = 93.4 kPa, or 9.34×10^1 kPa

Explain

Graham's Law

USE VISUALS Have students study the photographs in Figure 14.17. Explain that diffusion is a relatively slow process whose rate is inversely proportional to the square root of the molar mass of the gas.

Explore

Teacher Demo

PURPOSE Students compare effusion rates of helium and air.

MATERIALS round, identical balloons; helium; metric tape measure.

SAFETY Wear safety goggles when handling balloons.

PROCEDURE Fill two identical, round nonlatex balloons with equal volumes of helium and air. Have volunteers measure the circumferences of the balloons. One day later, they should measure the circumferences again.

EXPECTED OUTCOME Helium effused from the balloon at a faster rate.

Misconception Alert

Be sure to tell students that effusion requires that a gas effuses into a vacuum or that two gases effuse into each other with no other molecules present. It's unlikely that students have seen a demonstration of true effusion.

Graham's Law

How does the molar mass of a gas affect the rate at which the gas diffuses or effuses?

READING SUPPORT

Build Vocabulary: *Prefixes*

Diffusion and *effusion* come from the Latin *fundere* meaning "to pour." They differ only in their prefixes. The prefix *dif-* means "apart." The prefix *ex-* means "out." ***How do these prefixes help to contrast what happens to a gas during diffusion and effusion?***

Suppose you open a perfume bottle in one corner of a room. At some point, a person standing in the opposite corner will be able to smell the perfume. Molecules in the perfume evaporate and diffuse, or spread out, through the air in the room. **Diffusion** is the tendency of molecules to move toward areas of lower concentration until the concentration is uniform throughout.

The photo sequence in Figure 14.17 illustrates the diffusion process for bromine vapor. In Figure 14.17a, a glass cylinder containing air is inverted and sealed onto a cylinder containing bromine vapor. Figure 14.17b shows the bromine vapor diffusing through the air. The bromine vapor in the bottom cylinder has started to move upward into the top cylinder, where there is a lower concentration of bromine. In Figure 14.17c, the bromine has diffused to the top of the column formed by the combined cylinders. The concentration of bromine is now the same throughout the column.

(a) A cylinder of air and a cylinder of bromine vapor are sealed together.

(b) Bromine vapor diffuses upward through the air.

(c) After several hours, bromine vapors reach the top of the column.

Figure 14.17 Diffusion The diffusion of one substance through another is a relatively slow process. **Describe** ***How does the concentration of bromine in the bottom part of the column change during this sequence?***

There is another process that involves the movement of molecules in a gas. This process is called effusion. During **effusion,** a gas escapes through a tiny hole in its container. With effusion and diffusion, the type of particle is important. **Gases of lower molar mass diffuse and effuse faster than gases of higher molar mass.**

Thomas Graham's Contribution The Scottish chemist Thomas Graham studied rates of effusion during the 1840s. From his observations, he proposed a law. **Graham's law of effusion** states that the rate of effusion of a gas is inversely proportional to the square root of the gas's molar mass. This law can also be applied to the diffusion of gases.

Differentiated Instruction

L2 STRUGGLING STUDENTS Have students work in groups to rank the relative rates of diffusion at a constant temperature for carbon dioxide, helium, and nitrogen. *(helium > nitrogen > carbon dioxide)*

LPR LESS PROFICIENT READERS If students are having difficulty remembering the difference between effusion and diffusion, have them draw and label a model of each, indicating the movement of the molecules.

L3 ADVANCED STUDENTS Have students compare the use of compressed gas at high altitudes and the use of compressed gas during deep water dives.

472 Chapter 14 • Lesson 4

Figure 14.18 Blimps
The cigar-shaped part of a blimp, called an envelope, is a sealed container of helium gas. **Infer** *What properties do you think are desirable for the materials used to make the envelope of a blimp?*

Graham's law makes sense if you know how the mass, velocity, and kinetic energy of a moving object are related. The expression that relates the mass (m) and the velocity (v) of an object to its kinetic energy (KE) is $\frac{1}{2}mv^2$. For the kinetic energy to be constant, any increase in mass must be balanced by a decrease in velocity. For example, a ball with a mass of 2 g must travel at 5 m/s to have the same kinetic energy as a ball with a mass of 1 g traveling at 7 m/s. There is an important principle here. If two objects with different masses have the same kinetic energy, the lighter object must move faster.

Comparing Effusion Rates The blimp shown in Figure 14.18 is inflated with helium, which is less dense than air. One of the challenges in maintaining blimps is to keep the helium from seeping out. You may have noticed that party balloons filled with either helium or air gradually deflate over time. Both helium atoms and the molecules in air can pass through the tiny pores in a latex balloon. But a helium-filled balloon will deflate faster than an air-filled balloon. Kinetic theory can explain the difference.

Suppose you have two balloons, one filled with helium and the other filled with air. If the balloons are at the same temperature, the particles in each balloon have the same average kinetic energy. But helium atoms are less massive than oxygen or nitrogen molecules. So the molecules in air move more slowly than helium atoms with the same kinetic energy. Because the rate of effusion is related only to a particle's speed, Graham's law can be written as follows for two gases, A and B.

$$\frac{\text{Rate}_A}{\text{Rate}_B} = \frac{\sqrt{\text{molar mass}_B}}{\sqrt{\text{molar mass}_A}}$$

In other words, the rates of effusion of two gases are inversely proportional to the square roots of their molar masses. Sample Problem 14.8 on the following page compares the effusion rates of helium and nitrogen.

CHEMISTRY & YOU

Q: *Why do balloons filled with helium deflate faster than balloons filled with air? Use Graham's law of effusion to explain your answer.*

Foundations for Math

SQUARE ROOTS Students should remember that when dividing one square root by another, they can simplify the problem by dividing before taking the square root. The order of operations is interchangeable because taking a square root is a form of division.

Have students study **Sample Problem 14.8** on the following page. Point out that the square root of 7.0 is 2.7. They can find the same answer by dividing the square root of 28.0 by the square root of 4.0.

Explain

CHEMISTRY & YOU Helium has a smaller molar mass than the nitrogen and oxygen molecules that make up air. So, according to Graham's law of effusion, helium atoms will effuse faster through the pores in rubber balloon.

CRITICAL THINKING Ask a student volunteer to read the second paragraph of the Comparing Effusion Rates section out loud. Have students consider the statement *But helium atoms are less massive than oxygen or nitrogen molecules.* Ask them to use their knowledge of atomic and molecular structure of the three gases and their knowledge of kinetic energy to explain why this statement is true. *(Helium is a monatomic gas while oxygen and nitrogen are diatomic. Thus, the masses of oxygen and nitrogen molecules are much greater than the mass of helium atoms. Since $KE = \frac{1}{2}mv^2$, the much smaller mass of the helium atoms gives them a much greater velocity compared to the oxygen and nitrogen molecules.)*

Challenge students to use the kinetic energy equation to show mathematically that the velocity of helium atoms is 2.8 times the velocity of oxygen molecules and 2.7 times the velocity of nitrogen molecules.

Answers

READING SUPPORT During diffusion, the particles move apart. During effusion, the particles move out of a container through a tiny hole. (Students may have trouble with the scientific definitions of *effusion* and *diffusion* because of the multiple, often overlapping, meanings of these terms in common usage. For example, in many dictionaries, one definition of *effuse* is "to spread out; diffuse; radiate.")

FIGURE 14.17 The bromine concentration in the bottom part of the column gradually decreases.

FIGURE 14.18 Sample answer: The envelope material should be strong, flexible, lightweight (so as not to make the blimp too heavy), and gastight (to prevent seepage of helium).

Explain

Sample Practice Problem

How many times as fast does helium (He) effuse compared to oxygen (O_2)? *(2.8 times as fast)*

Evaluate

Informal Assessment

Tell students that the partial pressures of oxygen and hydrogen gases in a container are both 100 kPa. **Ask** In which sample are there more molecules? In which sample do the molecules have greater average kinetic energy? *(Both gases have the same number of molecules and same average kinetic energy.)* About how many times as fast does helium diffuse compared to oxygen? *(Helium diffuses almost three times as fast as oxygen.)* Then have students complete the 14.4 Lesson Check.

Reteach

Remind students that *diffusion* is a general term that applies to molecules moving away from a region of high concentration. Effusion is a specific example of diffusion and involves molecules passing through a narrow opening. Graham's law applies to both.

SampleProblem 14.8

Comparing Effusion Rates

How much faster does helium (He) effuse than nitrogen (N_2) at the same temperature?

1 Analyze **List the knowns and the unknown.** Use Graham's law and the molar masses of the two gases to calculate the ratio of effusion rates.

KNOWNS
$\text{molar mass}_{He} = 4.0\ g$
$\text{molar mass}_{N_2} = 28.0\ g$

UNKNOWN
ratio of effusion rates = ?

2 Calculate **Solve for the unknown.** Helium effuses nearly three times faster than nitrogen at the same temperature.

Start with the equation for Graham's law of effusion.

$$\frac{\text{Rate}_{He}}{\text{Rate}_{N_2}} = \frac{\sqrt{\text{molar mass}_{N_2}}}{\sqrt{\text{molar mass}_{He}}}$$

Substitute the molar masses of nitrogen and helium into the equation.

$$\frac{\text{Rate}_{He}}{\text{Rate}_{N_2}} = \sqrt{\frac{28.0\ \cancel{g}}{4.0\ \cancel{g}}} = \sqrt{7.0} = 2.7$$

3 Evaluate **Does the result make sense?** Helium atoms are less massive than nitrogen molecules, so it makes sense that helium effuses faster than nitrogen.

39. Calculate the ratio of the velocity of hydrogen molecules to the velocity of carbon dioxide molecules at the same temperature.

Use what you know about chemical formulas and the mole to write the molar mass of each gas.

14.4 LessonCheck

40. Review In a mixture of gases, how is the total pressure determined?

41. Review What is the effect of molar mass on rates of diffusion and effusion?

42. Explain How is the partial pressure of a gas in a mixture calculated?

43. Calculate The pressure in an automobile tire filled with air is 245.0 kPa. If $P_{O_2} = 51.3$ kPa, $P_{CO_2} = 0.10$ kPa, and $P_{others} = 2.3$ kPa, what is P_{N_2}?

44. Compare What distinguishes effusion from diffusion? How are these processes similar?

45. Relate Cause and Effect Explain why the rates of diffusion of nitrogen gas and carbon monoxide are almost identical at the same temperature.

46. Analyze Data Both Table 14.1 on page 469 and the Elements in the Atmosphere table on page R1 list data on the composition of air. Look at the data included in each table. Identify two ways in which the tables are similar. Describe at least three differences.

Lesson Check Answers

40. Total pressure is equal to the sum of the partial pressures of the components.

41. Gases with lower molar masses diffuse and effuse faster than gases with higher molar masses.

42. Subtract the partial pressures of the other gases from the total pressure.

43. 191.3 kPa

44. During effusion, a gas escapes through a tiny hole in its container. In both cases, the rate depends on the molar mass.

45. Carbon monoxide and nitrogen have almost identical molar masses when the masses are rounded to two significant figures (28 g).

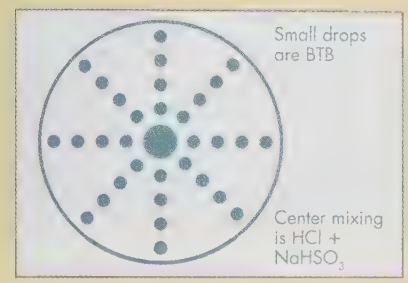
46. Both tables report data for dry air as mainly nitrogen and oxygen. Table 14.1 uses percents and includes a compound. The table on R1 uses ppm and provides specific data for elements.

Small-Scale Lab

Diffusion

Purpose

To infer diffusion of a gas by observing color changes during chemical reactions



Materials

- clear plastic cup or petri dish
- reaction surface
- dropper bottles containing bromothymol blue, hydrochloric acid, and sodium hydrogen sulfite
- ruler
- cotton swab
- NaOH, NH_4Cl (optional)

Procedure

1. Use the plastic cup or petri dish to draw the large circle shown below on a sheet of paper.

2. Place a reaction surface over the grid and add small drops of bromothymol blue (BTB) in the pattern shown by the small circles. Make sure the drops do not touch one another.

3. Mix one drop each of hydrochloric acid (HCl) and sodium hydrogen sulfite ($NaHSO_3$) in the center of the pattern.

4. Place the cup or petri dish over the grid and observe what happens.

5. If you plan to do Activity 1 in the You're the Chemist section, don't dispose of your materials yet.

Analyze

1. Observe Describe in detail the changes you observed in the drops of BTB over time. Draw pictures to illustrate the changes.

2. Describe Draw a series of pictures showing how one of the BTB drops might look over time if you could view the drop from the side.

3. Explain The BTB changed even though you added nothing to it. If the mixture in the center circle produced a gas, would this explain the change in the drops of BTB? Use kinetic theory to explain your answer.

4. Describe Translate the following word equation into a balanced chemical equation: Sodium hydrogen sulfite reacts with hydrochloric acid to produce sulfur dioxide gas, water, and sodium chloride.

You're the Chemist

The following activities allow you to develop your own procedures and analyze the results.

1. Analyze Data Carefully absorb the center mixture of the original experiment onto a cotton swab and replace it with one drop of NaOH and one drop of NH_4Cl. Describe what happens and explain in terms of kinetic theory. Ammonium chloride reacts with sodium hydroxide to produce ammonia gas, water, and sodium chloride. Write and balance a chemical equation to describe this reaction.

2. Design an Experiment Design an experiment to observe the effect of the size of the BTB drops on the rate at which they change. Explain your results in terms of kinetic theory.

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the lab. Make sure each group has ELLs of varied language proficiencies so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Restate each step in simple sentences. Demonstrate each step, and then have students perform it before proceeding to the next step.

INTERMEDIATE: LOW/HIGH Paraphrase the procedure and Analyze and Conclude questions for students.

ADVANCED: LOW/HIGH Have students assist classmates with lower language proficiency in understanding procedures and drafting answers.

Explore

Small-Scale Lab

OBJECTIVE After completing this activity, students will be able to infer diffusion of a gas by observing color changes during reaction.

SKILLS FOCUS inferring, drawing conclusions

PREP TIME 30 minutes

CLASS TIME 40 minutes

ADVANCE PREPARATION

Solution	Preparation
1.0*M* HCl	82 mL of 12*M* in 1.0 L
0.04% BTB	100 mg in 16.0 mL 0.01*M* NaOH, dilute to 250 mL
0.5*M* NaOH	20.0 g in 1.0 L
1.0*M* NH_4Cl	13.4 g in 250 mL
0.4*M* $NaNO_2$	6.9 g in 250 mL
0.1*M* KI	4.2 g in 250 mL
1.0*M* $NaHSO_3$	26 g in 250 mL

SAFETY Always slowly add acid to water.

TEACHING TIPS Before class, add a drop of BTB to the paper to be sure the paper is not acidic. The BTB should remain blue.

EXPECTED OUTCOME The drops of BTB turn yellow, starting with those closest to the center.

ANALYZE AND CONCLUDE

1. The drops near the center change immediately. As the gas diffuses, all the drops change color. The color change begins at the outer edge of each drop.
2. Students' drawings will vary.
3. The particles of gas produced are in motion. As the particles diffuse from the center, they collide and react with molecules of BTB.
4. $NaHSO_3 + HCl \rightarrow SO_2 + H_2O + NaCl$

YOU'RE THE CHEMIST

1. As the ammonia diffuses, BTB changes from yellow to blue.

   $NH_4CL + NaOH \rightarrow NH_4 + H_2O + NaCl$
2. Vary the size of the BTB drops from "pinheads" to "puddles." Tiny drops are better able to detect small quantities of gas.

FOR ENRICHMENT Have students design an experiment that shows the effect of temperature on rate of diffusion. (The drops change color more quickly at higher temperatures.)

Answers

39. 4.7

CHEMISTRY & YOU Draw students' attention to the photos of the CNG fueling station and the pressurized NGV fuel tank. Emphasize that CNG is a gas—unlike gasoline, which is a liquid. Call on volunteers to identify the local price of gasoline. Some students' answers may not specify volumetric units. Explain that the price is in fact a ratio expressed as dollars ($) per gallon.

Pose the following question to the students: ***Knowing that CNG is a gas and gasoline is a liquid, how would environmental factors play a role in determining the price of CNG?*** You may need to guide the students in the following ways:

- Temperature and pressure do not significantly affect the volume of liquid gasoline.
- Price assumes that the volume is constant.
- Gases are easily compressed into smaller volumes.
- A gallon of natural gas at a high pressure contains more representative particles than a gallon of natural gas at a low temperature.

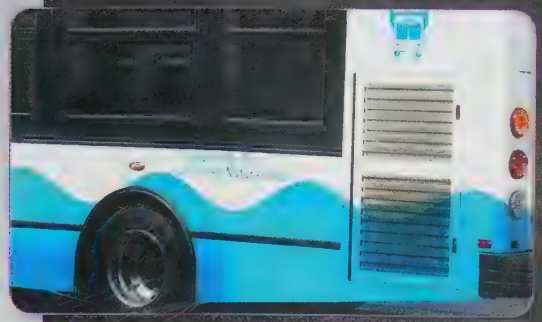
CHEMISTRY & YOU: TECHNOLOGY

Natural Gas Vehicles

Most of the cars you see on the road run on gasoline, better known as gas—although the fuel itself is a liquid, not a gas. But in some U.S. cities, as well as parts of South America and Asia, vehicles that run on gaseous fuel are becoming increasingly common.

A natural gas vehicle, or NGV, runs on compressed natural gas (CNG), which is natural gas that has been compressed to less than 1 percent of its volume at standard pressure. The fuel is stored in a pressurized cylinder. Like other vehicles that burn fossil fuels, NGVs emit CO_2. However, natural gas burns cleaner than gasoline or diesel fuel. Many gasoline-powered cars can be retrofitted with NGV technology so that the driver can choose to run the car on either gasoline or CNG.

Pros & Cons



Advantages of NGVs	Disadvantages of NGVs
✔ **Less pollution** NGVs produce much less carbon monoxide, nitrogen oxides, and toxins than gasoline-powered vehicles.	✘ **More expensive** NGVs tend to cost more than comparable gasoline-powered cars.
✔ **Less maintenance** Because natural gas burns cleaner than gasoline, the engines of NGVs require less servicing than those of gasoline-powered vehicles.	✘ **Less roomy** Due to the CNG tank, NGVs have less trunk space.
✔ **Cheaper fuel** Natural gas costs less than gasoline.	✘ **Limited travel range** On a single tank of gas, NGVs can travel only about 60 percent as far as gasoline-powered cars before needing more fuel.
✔ **Safety** The fuel tanks in NGVs are stronger and safer than gasoline storage tanks.	✘ **Hard to refuel** CNG refueling stations are currently few and far between.
	✘ **Still fossil-fueled** Like oil, natural gas is a nonrenewable resource.

21st Century Learning To be successful in the 21st century, students need skills and learning experiences that extend beyond subject matter mastery. The following project helps students build the following 21st Century Skills: Financial, *Economic, Business, and Entrepreneurial Literacy; Creativity and Innovation; Communication and Collaboration; Information, Media, and Technology Literacy; Initiative and Self-Direction; Social Skills; and Productivity and Accountability.*

SELL THAT CAR! Pose the following challenge to your students. ***A major automobile manufacturer has just introduced an NGV to its lineup of cars. The manufacturer is in need of a marketing firm to create an ad campaign promoting the new model. Form a "firm" of 3–5 people to do the following:*** **Create a TV or magazine ad campaign that will be presented to the class.**

- The ad should be based on facts about NGVs currently on the market.
- The ad should describe how these types of cars are different from gasoline-powered vehicles.

ON THE ROAD Most of the NGVs found in the United States are buses. But don't be surprised if you start to see passenger cars sporting the "NGV" logo.

FILL 'ER UP Any building with a natural gas line can be equipped with a pressurized fueling device that delivers CNG. But NGV drivers must be patient—an empty CNG tank takes much longer to fill than an empty gasoline tank.

A REAL GAS IN THE GAS TANK A mid-sized NGV sedan has a fuel tank in the back with a volume of 8 gallons, or 30 L. At ambient temperatures, the pressure inside a full tank of CNG is about 3600 pounds per square inch (psi), or 25,000 kPa.

Take It Further

1. Calculate The natural gas in a 30-L NGV fuel tank has a pressure of 2.05×10^4 kPa at a temperature of 297 K. How many kilograms of fuel are in the tank? (Use a molar mass of 19 g/mol for natural gas.)

2. Calculate Natural gas is 89% methane (CH_4), 5% ethane (C_2H_6), 5% butane (C_4H_{10}), and 1% propane (C_3H_8). Use the data from Question 1 to determine the partial pressures of each component gas in the fuel tank.

Differentiated Instruction

L1 STRUGGLING STUDENTS If your students have trouble with Question 1, have them review Practice Problem 14.5 (on the ideal gas law) in Lesson 14.3. If students have trouble with Question 2, have them review Practice Problem 14.7 (on Dalton's law of partial pressures) in Lesson 14.4.

LPR LESS PROFICIENT READERS

VIRTUAL LAB Assign the lab simulation Real vs. Ideal Gases in **Virtual ChemLab.** Natural gas contains mostly methane (CH_4). Ask students to investigate the conditions under which methane deviates from ideal gas behavior.

Explain

START A CONVERSATION After students read the feature, begin a discussion of NGVs. Ask students to compare NGVs and gasoline-powered cars. **Ask** Why do you think NGVs have become common in some densely populated cities, such as Bangkok and Rio de Janeiro? *(Because NGVs have a more limited travel range than gasoline-powered cars and because CNG refueling stations are not yet as common as (liquid) gas stations, NGVs are better suited to city driving than highway driving.)*

Extend

NATURAL GAS VEHICLES Have students do research on electric cars and fuel-cell cars. Ask them to create a pros-and-cons table for each type of car (similar to the one for NGVs). Ask them to suggest how the technology of NGVs, electric cars, and fuel-cell cars might be improved to meet the needs of everyday drivers.

Connect to MATH

The standard cubic foot (scf) is a unit used to measure the quantity of a gas. 1 scf equals the amount of gas filling 1 ft^3 at 14.73 psi and 60°F (101.6 kPa and 289 K). To compare mileages of gasoline-powered cars with those of NGVs, 1 gallon of gasoline is considered equivalent to 125 scf of natural gas.

Answers

TAKE IT FURTHER

1. 4.7 kg
2. $P_{methane} = 1.82 \times 10^4$ kPa
   $P_{ethane} = P_{butane} = 1.03 \times 10^3$ kPa
   $P_{propane} = 2.05 \times 10^2$ kPa

Review and Assessment Resources

WALK-THRU TUTORIALS Each of the Math Tune-Up problems on the following page has an animated step-by-step tutorial that explains the problem-solving strategy in detail.

PROBLEM SETS Have students practice more gas law problems by using the Chapter 14 Online Problem Set.

MATH SKILLS REVIEW Have struggling students practice solving algebraic equations by using the MathXL learning module.

VIRTUAL LABS Have students complete a virtual lab as an in-class or take-home assignment to help reinforce the mathematical relationships described by the gas laws. To help students investigate Boyle's law and Charles's law, assign the labs Pressure-Volume Relationship for Gases and Temperature-Volume Relationship for Gases in Virtual ChemLab.

VIRTUAL LABS Assign Derivation of the Ideal Gas Law in Virtual ChemLab to reinforce the ideal gas law; students use experimental data to calculate the value of the ideal gas constant.

14 Study Guide

BIG IDEA KINETIC THEORY

Ideal gases conform to the assumptions of kinetic theory. The behavior of ideal gases can be predicted by the gas laws. With the ideal gas law, the number of moles of a gas in a fixed volume at a known temperature and pressure can be calculated. Although an ideal gas does not exist, real gases behave ideally under a variety of temperature and pressure conditions.

14.1 Properties of Gases

- Gases are easily compressed because of the space between the particles in a gas.
- The amount of gas (n), volume (V), and temperature (T) are factors that affect gas pressure (P).

- compressibility (450)

14.2 The Gas Laws

- If the temperature is constant, as the pressure of a gas increases, the volume decreases.
- As the temperature of an enclosed gas increases, the volume increases if the pressure is constant.
- As the temperature of an enclosed gas increases, the pressure increases if the volume is constant.
- When only the amount of gas is constant, the combined gas law describes the relationship among pressure, volume, and temperature.

- Boyle's law (456)
- Charles's law (458)
- Gay-Lussac's law (460)
- combined gas law (462)

Key Equations

Boyle's law: $P_1 \times V_1 = P_2 \times V_2$

Gay-Lussac's law: $\frac{P_1}{T_1} = \frac{P_2}{T_2}$

Charles's law: $\frac{V_1}{T_1} = \frac{V_2}{T_2}$

combined gas law: $\frac{P_1 \times V_1}{T_1} = \frac{P_2 \times V_2}{T_2}$

14.3 Ideal Gases

- When the pressure, volume, and temperature of a contained gas are known, you can use the ideal gas law to calculate the number of moles of the gas.
- Real gases differ most from an ideal gas at low temperatures and high pressures.

- ideal gas constant (465)
- ideal gas law (465)

Key Equation

ideal gas law:
$P \times V = n \times R \times T$ or $PV = nRT$

14.4 Gases: Mixtures and Movements

- In a mixture of gases, the total pressure is the sum of the partial pressures of the gases.
- Gases of lower molar mass diffuse and effuse faster than gases of higher molar mass.

- partial pressure (469)
- Dalton's law of partial pressure (470)
- diffusion (472)
- effusion (472)
- Graham's law of effusion (472)

Key Equations

Dalton's law: $P_{total} = P_1 + P_2 + P_3 + \ldots$

Graham's law: $\frac{\text{Rate}_A}{\text{Rate}_B} = \sqrt{\frac{\text{molar mass}_B}{\text{molar mass}_A}}$

UbD Performance Tasks

MARINE ANIMALS Have students research how the tremendous pressure of the water affects the blood gases of marine animals when they dive. Have the students present their findings to the class, using photographs or chats.

UP, UP, AND AWAY Have students research what happens to helium-filled rubber and plastic film balloons when they are released into the atmosphere. Have students write a report detailing the events in terms of the applicable gas laws.

Math Tune-Up: Gas Law Problems

Problem	❶ Analyze	❷ Calculate	❸ Evaluate
A 2.50-L sample of nitrogen gas at a temperature of 308 K has a pressure of 1.15 atm. What is the new volume of the gas if the pressure is increased to 1.80 atm and the temperature is decreased to 286 K?	Knowns: $P_1 = 1.15$ atm $V_1 = 2.50$ L $T_1 = 308$ K $P_2 = 1.80$ atm $T_2 = 286$ K Unknown: $V_2 = ?$ Use the combined gas law: $\frac{P_1 \times V_1}{T_1} = \frac{P_2 \times V_2}{T_2}$	Solve for V_2 and calculate: $V_2 = \frac{P_1 V_1 T_2}{P_2 T_1}$ $V_2 = \frac{(1.15\ \cancel{\text{atm}})(2.50\ \text{L})(286\ \cancel{\text{K}})}{(1.80\ \cancel{\text{atm}})(308\ \cancel{\text{K}})}$ $V_2 = 1.48$ L	An increase in pressure causes the volume of a gas to decrease. Likewise, a decrease in temperature causes the volume of a gas to decrease. So, V_2 should be smaller than V_1. The answer makes sense. Hint: Review Sample Problem 14.4 if you have trouble with the combined gas law.
How many moles of helium gas fill a 6.45-L balloon at a pressure of 105 kPa and a temperature of 278 K?	Knowns: $P = 105$ kPa $V = 6.45$ L $T = 278$ K $R = 8.31$ L·kPa/K·mol Unknown: $n = ?$ Use the ideal gas law: $PV = nRT$	Solve for n and calculate: $n = \frac{PV}{RT}$ $n = \frac{(105\ \cancel{\text{kPa}})(6.45\ \cancel{\text{L}})}{\left(8.31 \frac{\cancel{\text{L}} \cdot \cancel{\text{kPa}}}{\cancel{\text{K}} \cdot \text{mol}}\right)(278\ \cancel{\text{K}})}$ $n = 0.293$ mol	The gas is not at high pressure, nor is the volume large. So the number of moles in the balloon should be small. The answer is reasonable, and the units have canceled correctly.
A gas mixture containing argon, krypton, and helium has a total pressure of 376 kPa. If the partial pressures of argon and krypton are 92 kPa and 144 kPa, respectively, what is the partial pressure of helium?	Knowns: $P_{total} = 376$ kPa $P_{Ar} = 92$ kPa $P_{Kr} = 144$ kPa Unknown: $P_{He} = ?$ Dalton's law of partial pressures applies: $P_{total} = P_{Ar} + P_{He} + P_{Kr}$	Solve for P_{He} and calculate: $P_{He} = P_{total} - (P_{Ar} + P_{Kr})$ $P_{He} = 376$ kPa $-$ (92 kPa + 144 kPa) $P_{He} = 140$ kPa $P_{He} = 1.40 \times 10^2$ kPa	The partial pressure of helium must be less than half the total pressure. The answer is reasonable. Dalton's law: The total pressure exerted by a mixture of gases (P_{total}) is equal to the sum of the partial pressures of the component gases.

Focus on ELL

5 ASSESS UNDERSTANDING Have ELLs complete one of the Performance Tasks as a group for an alternative assessment. Provide guidelines on the information that it must cover, and provide a grading rubric.

BEGINNING

LOW Have students create visuals for the presentation.

HIGH Have students provide simple labels or captions as needed.

INTERMEDIATE: LOW/HIGH Have students provide more extended written descriptions for the visuals.

ADVANCED: LOW/HIGH Have students give the oral presentation to the class.

Math Review

Example and sample practice problems for the various gas laws can be found on the following pages:

LESSON 14.2 Boyle's law—page 421; Charles's law—page 423; Gay-Lussac's law—page 425; the combined gas law—page 426

LESSON 14.3 The ideal gas law—pages 429 and 430

LESSON 14.4 Dalton's law of partial pressures—435; Graham's law of effusion—page 438

ASSESSMENT

Evaluate

Answers

LESSON 14.1

47. The space between particles is reduced.

48. The increased kinetic energy of the particles causes collisions to occur more frequently and with more force.

49. The volume decreases. The molecules have less kinetic energy and cause less pressure on the inside of the balloon.

50. The pressure doubles.

51. The pressure quadruples.

52. As particles are removed from the container, there is a decrease in the number of collisions.

LESSON 14.2

53. $V_1/T_1 = V_2/T_2$
V_1 and V_2 are the initial and final volumes; T_1 and T_2 are the initial and final temperatures.

54. 1.00×10^2 kPa

55. 1.80 L

56. 18 L

57. 846 K (573°C)

58. 200 K (-73°C)

59. $(P_1V_1)/T_1 = (P_2V_2)/T_2$

60. 1.10×10^3 kPa

61. 2.58 kPa

62. When the volume is constant, $V_1 = V_2$, so the volume terms cancel, leaving the equation for Gay-Lussac's law.

LESSON 14.3

63. Its particles have no volume, there are no attractions between them, and collisions are elastic. An ideal gas follows the gas laws at all temperatures and pressures.

64. Particles in a real gas have a finite volume and are attracted to one another at low temperatures and high pressures.

65. 33.0 L

66. 17.6 L

67. 3.60×10^2 kPa

68. 1.71×10^3 kPa

69. 42 g

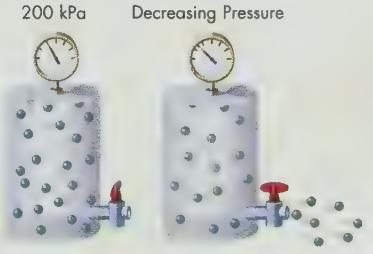
14 Assessment

* Solutions appear in Appendix E

Lesson by Lesson

14.1 Properties of Gases

47. What happens to the particles in a gas when the gas is compressed?



48. Explain why heating a contained gas that is held at a constant volume increases its pressure.

49. Describe what happens to the volume of a balloon when it is taken outside on a cold winter day. Explain why the observed change happens.

50. A metal cylinder contains 1 mol of nitrogen gas. What will happen to the pressure if another mole of gas is added to the cylinder, but the temperature and volume do not change?

51. If a gas is compressed from 4 L to 1 L and the temperature remains constant, what happens to the pressure?

52. Use the drawing to help explain why gas pressure decreases when gas is removed from a container with a fixed volume.

14.2 The Gas Laws

53. Write the mathematical equation for Charles's law and explain the symbols.

***54.** The gas in a closed container has a pressure of 3.00×10^2 kPa at 30°C (303 K). What will the pressure be if the temperature is lowered to −172°C (101 K)?

55. Calculate the volume of a gas (in L) at a pressure of 1.00×10^2 kPa if its volume at 1.20×10^2 kPa is 1.50×10^3 mL.

56. A gas with a volume of 4.0 L at 90.0 kPa expands until the pressure drops to 20.0 kPa. What is its new volume if the temperature doesn't change?

***57.** A gas with a volume of 3.00×10^2 mL at 150.0°C is heated until its volume expands to 6.00×10^2 mL. What is the new temperature of the gas if the pressure remains constant during the heating process?

***58.** A gas with a volume of 15 L at 327°C is cooled at constant pressure until the volume reaches 5 L. What is the new temperature of the gas?

59. Write the mathematical expression for the combined gas law.

60. A sealed cylinder of gas contains nitrogen gas at 1.00×10^3 kPa pressure and a temperature of 20°C. When the cylinder is left in the sun, the temperature of the gas increases to 50°C. What is the new pressure in the cylinder?

***61.** A sample of nitrogen gas has a pressure of 6.58 kPa at 539 K. If the volume does not change, what will the pressure be at 211 K?

62. Show how Gay-Lussac's law can be derived from the combined gas law.

14.3 Ideal Gases

63. Describe an ideal gas.

64. Explain why it is impossible for an ideal gas to exist.

***65.** What is the volume occupied by 1.24 mol of a gas at 35°C if the pressure is 96.2 kPa?

66. What volume will 12.0 g of oxygen gas (O_2) occupy at 25°C and a pressure of 52.7 kPa?

***67.** If 4.50 g of methane gas (CH_4) is in a 2.00-L container at 35°C, what is the pressure in the container?

68. What pressure is exerted by 0.450 mol of a gas at 25°C if the gas is in a 0.650-L container?

***69.** A helium-filled weather balloon has a volume of 2.4×10^2 L at 99 kPa pressure and a temperature of 0°C. What is the mass of the helium in the balloon?

14.4 Gases: Mixtures and Movements

70. In your own words, state Dalton's law of partial pressure.

71. Which gas effuses faster: hydrogen or chlorine? How much faster?

72. Which gas effuses faster at the same temperature: molecular oxygen or atomic argon?

***73.** Calculate the ratio of the velocity of helium atoms to the velocity of neon atoms at the same temperature.

74. Calculate the ratio of the velocity of helium atoms to the velocity of fluorine molecules at the same temperature.

Understand Concepts

75. How does kinetic theory explain the compressibility of gases?

76. A teacher adds enough water to cover the bottom of an empty metal can with a screw cap. Using a stove, the teacher heats the can with the cap off until the water boils, and then screws on the cap tightly. When the sealed can is dunked in cold water, the sides of the can immediately collapse inward as though crushed in a trash compactor.

a. Use kinetic theory to explain why the can collapsed inward.

b. If the experiment were done with a dry can, would the results be similar? Explain.

77. Explain how the compressed gas in an aerosol can forces paint out of the can. Make sure to describe how the gas pressure inside the can changes as the paint is sprayed. (Refer to Figure 14.5 in Lesson 14.1.)

78. Why do aerosol containers display the warning, "Do not incinerate"?

79. The manufacturer of an aerosol deodorant packaged in a 150-mL container plans to produce a container of the same size that will hold twice as much gas. How will the pressure of the gas in the new product compare with that of the gas in the original container?

80. Why must Kelvin temperatures be used in calculations that involve gases?

81. Explain how using a pressure cooker reduces the time required to cook food.

82. The ratio of two variables is always a constant. What can you conclude about the relationship between the two variables?

***83.** A 3.50-L gas sample at 20°C and a pressure of 86.7 kPa expands to a volume of 8.00 L. The final pressure of the gas is 56.7 kPa. What is the final temperature of the gas in degrees Celsius?

84. Explain the reasons why real gases deviate from ideal behavior.

85. How would the number of particles of two gases compare if their partial pressures in a container were identical?

86. Why does a balloon filled with helium deflate more quickly than a balloon filled with air?

***87.** A certain gas effuses four times as fast as oxygen (O_2). What is the molar mass of the gas?

***88.** During an effusion experiment, a certain number of moles of an unknown gas passed through a tiny hole in 75 seconds. Under the same conditions, the same number of moles of oxygen gas passed through the hole in 30 seconds. What is the molar mass of the unknown gas?

89. The photograph shows a tube with cotton balls at each end. The cotton ball at the left was soaked with hydrochloric acid. The cotton ball on the right was soaked with a solution of ammonia. When these compounds react, they form a white solid, ammonium chloride. Based on the location of the ammonium chloride in the tube, which gas diffuses at a faster rate, hydrogen chloride or ammonia? Explain.

ASSESSMENT

Answers

LESSON 14.4

70. The total pressure of a gaseous mixture is equal to the sum of the individual pressures of each gas.

71. Hydrogen gas diffuses faster than chlorine gas by an approximate factor of six.

72. molecular oxygen

73. 2.25:1

74. 3.08:1

UNDERSTAND CONCEPTS

75. Gases are easily compressed because there is a lot of space between the particles.

76. **a.** Boiling the water fills the can with steam. When the can is plunged into cold water, the steam is trapped and rapidly condenses, reducing gas pressure inside the can. The walls of the can are not strong enough to withstand the comparatively high atmospheric pressure, which crushes the can.
b. The results would be much less dramatic. The change in volume (and in internal pressure) from heated air to cold air is much less dramatic than when steam (a vapor) condenses to water (a liquid).

77. The gas propellant inside the can is at a higher pressure than the air outside the can. When the valve at the top of the can is opened, gas rushes out of the can, propelling the paint in the process. The pressure of the propellant decreases as the can is used. When there is no longer a pressure difference between the propellant and the outside air, the can no longer works.

78. High temperatures increase the pressure of the contents of the container and may cause it to explode.

79. The pressure will double.

80. Temperatures measured on the Kelvin scale are directly proportional to the average kinetic energy of the particles. Celsius temperatures are not.

81. The water boils at a higher temperature, which speeds the cooking process.

82. The variables are directly proportional.

83. 165°C

84. The particles in a real gas have a finite volume and are attracted to one another.

85. The number of particles would be equal.

86. Helium atoms have a smaller molar mass than oxygen and nitrogen molecules and effuse faster through pores in the balloon.

87. 2.0 g

88. 2.0×10^2 g

89. Ammonia diffuses faster than hydrogen chloride. Based on the location of the reaction product, the ammonia molecules travel about twice the distance of the hydrogen chloride molecules, in the same time.

ASSESSMENT

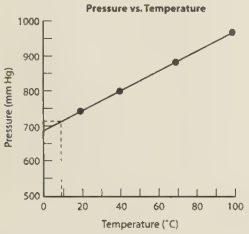
Answers

THINK CRITICALLY

90. A vacuum contains no matter to allow the transfer of kinetic energy between molecules.

91. The gases that make up the atmosphere, just like any other form of matter, are held near Earth by the force of gravity.



92. Helium gas is composed of small atoms with little attraction for each other.

93. The partial pressure of oxygen would be greater than at sea level, because the atmospheric pressure would be greater than at sea level.

94. **a.** 1.63×10^2 kPa
b. 4.49×10^2 kPa

95. There could be different amounts of each gas, or the gases could be at different pressures.

96. **a.**

b. 700 mm Hg
c. directly proportional
d. The pressure rises 2.4 mm Hg for every 1°C increase in temperature.
e. $P = (2.4 \text{ mm Hg/°C})T + 700 \text{ mm Hg}$
f. Gay-Lussac's law

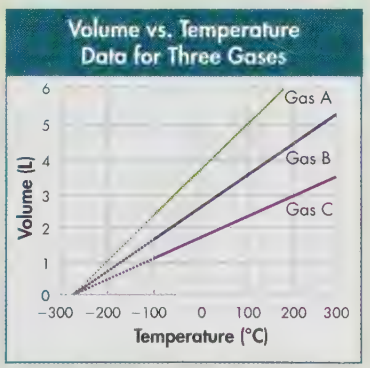
97. **a.** methane at 200°C
b. Attractions between the particles and the physical volume of the particles. At 0°C, the methane molecules are moving relatively slowly. The attractions between the molecules are sufficiently strong so that, at low pressures, the curve is below the $PV/nRT = 1$ line. At higher pressures, the space between molecules is reduced. The actual physical volume of the methane molecules now becomes more important, and the curve is above the $PV/nRT = 1$ line.

Think Critically

90. **Infer** Figure 14.14 in Lesson 14.3 shows an insulated tank used to store liquid nitrogen. How does the vacuum between the walls of the tank prevent heat transfer?

91. **Infer** Gases will diffuse from a region of higher concentration to a region of lower concentration. Why don't the gases in Earth's atmosphere escape into the near-vacuum of space?

92. **Apply Concepts** What real gas comes closest to having the characteristics of an ideal gas? Explain your answer.



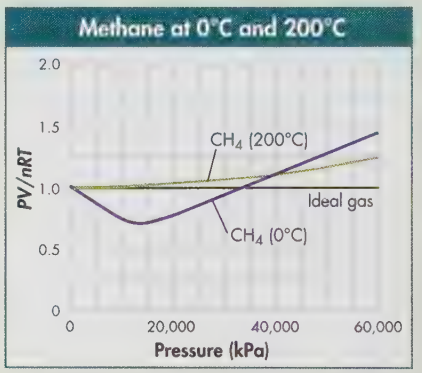
93. **Predict** Death Valley in California is at 86 m below sea level. Will the partial pressure of oxygen in Death Valley be the same, lower, or higher than the partial pressure of oxygen at sea level? Give a reason for your answer.

***94.** **Calculate** The following reaction takes place in a sealed 40.0-L container at a temperature of 120°C:

$$4NH_3(g) + 5O_2(g) \longrightarrow 4NO(g) + 6H_2O(g)$$

a. When 34.0 g of NH_3 reacts with 96.0 g of O_2, what is the partial pressure of NO in the sealed container?
b. What is the total pressure in the container?

95. **Interpret Graphs** The graph shows the direct relationship between volume and temperature for three different gas samples. Offer at least one explanation for why the graphs are not identical for the three samples. (*Hint:* What variables other than temperature and volume can be used to describe a gas?)



***96.** **Analyze Data** A student collected the following data for a fixed volume of gas.

Temperature (°C)	Pressure (mm Hg)
10	726
20	750
40	800
70	880
100	960

a. Graph the data, using pressure as the dependent variable.
b. What is the pressure of the gas at 0°C?
c. Is the relationship between the variables directly or inversely proportional?
d. How does the pressure of the gas change with each degree Celsius change in the temperature?
e. Write an equation relating the pressure and temperature of the gas.
f. Which gas law is illustrated by the data? Select two data points on your graph to confirm your answer.

97. **Interpret Graphs** The graph shows how the ratio (PV/nRT) changes with increasing pressure for methane (CH_4) at 0°C and 200°C.

a. At lower pressures, which gas behaves more like an ideal gas: methane at 0°C or methane at 200°C.
b. The curve for methane at 0°C shows that the ratio PV/nRT is less than 1 at lower pressures and greater than 1 at higher pressures. What characteristics of real gases can explain these deviations?

Enrichment

98. Analyze Data Oxygen is produced in the laboratory by heating potassium nitrate (KNO_3). The data table below gives the volume of oxygen produced at STP from different quantities of KNO_3. Use the data to determine the mole ratio by which KNO_3 and O_2 react.

Mass of KNO_3 (g)	Volume of O_2 (cL)
0.84	9.3
1.36	15.1
2.77	30.7
4.82	53.5
6.96	77.3

***99. Calculate** A mixture of ethyne gas (C_2H_2) and methane gas (CH_4) occupied a certain volume at a total pressure of 16.8 kPa. When the sample burned, the products were CO_2 gas and H_2O vapor. The CO_2 was collected and its pressure found to be 25.2 kPa in the same volume and at the same temperature as the original mixture. What percentage of the original mixture was methane?

***100. Calculate** A 0.10-L container holds 3.0×10^{20} molecules of H_2 at 100 kPa and 0°C.

a. If the volume of a hydrogen molecule is 6.7×10^{-24} mL, what percentage of the volume of the gas is occupied by its molecules?

b. If the pressure is increased to 100,000 kPa, the volume of the gas is 1×10^{-4} L. What fraction of the total volume do the hydrogen molecules now occupy?

101. Draw Conclusions Many gases that have small molecules, such as N_2 and O_2, have the expected molar volume of 22.41 L at STP. However, other gases behave in a very non-ideal manner, even if extreme pressures and temperatures are not involved. The molar volumes of CH_4, CO_2, and NH_3 at STP are 22.37 L, 22.26 L, and 22.06 L, respectively. Explain the reasons for these large departures from the ideal.

Write About Science

102. Explain Why does a tennis ball bounce higher in the summer than it does in the winter? Use what you know about gas behavior to explain your answer.

103. Research a Problem Cars that run on natural gas or hydrogen require different fuel tanks and different refueling stations than cars that run on gasoline, which is a liquid at STP. How would you design a fuel tank for storing a gas? How would you design a gas pump that pumped a gas instead of a liquid? Research a kind of vehicle that runs on gaseous fuel and explain how these questions have been addressed.

CHEMYSTERY

Under Pressure

Becki realized that she had decompression sickness, also known as the bends. Recreational divers use regulators attached on their air tank to "regulate" the air they breathe in so that it's at the same pressure as the pressure outside their bodies. Although the fractions of nitrogen and oxygen in her air supply remained constant under high pressure, the partial pressure of each component gas increased. Therefore, with each breath under water, she was receiving more nitrogen and oxygen than normal.

As Becki ascended and the pressure on her body decreased, the excess nitrogen formed bubbles in her blood and tissues, causing pain and other symptoms. Serious cases of the bends require treatment in a high-pressure chamber. The pressure is reduced gradually so that the excess nitrogen can leave the body harmlessly.

104. Infer How could Becki have prevented getting the bends?

105. Connect to the BIGIDEA What would have happened if Becki held her breath while ascending from a dive? Use the gas laws to explain.

ASSESSMENT

CHEMYSTERY After students have read through the CHEMystery, call on volunteers to summarize how the behavior of gases helps explain why Becki fell ill after her dives.

Ask Why does Becki breathe in more nitrogen and oxygen during her dives? *(As Becki dives, the pressure of the air she breathes increases. Although the composition of the gases in the air doesn't change with increasing pressure, their partial pressures do. Therefore, with each breath, she breathes in more nitrogen and oxygen underwater than she does at the surface.)* **Ask** What caused the pain that Becki experienced after her dives? *(As Becki ascended from her dives, the pressure decreased and the nitrogen formed bubbles in her blood and tissues, which caused pain.)*

CHEMYSTERY ANSWERS

104. Becki could have prevented getting the bends by ascending slowly. This would have allowed the excess nitrogen to leave her body harmlessly.

105. BIGIDEA Holding her breath while ascending would cause the volume of the gases in Becki's lungs to increase. This could cause her lungs to rupture if she does not exhale.

Answers

ENRICHMENT

98. 2 mol KNO_3 for each 1 mol O_2

99. 50% CH_4

100. a. 2.0×10^{-3}%

b. 2.0%

101. Because attractions between molecules in gases such as nitrogen and oxygen are insignificant, these gases have the molar volume of an ideal gas, 22.4 L at STP. Based on their molar volumes at STP, there are attractions between molecules of CH_4, CO_2, and NH_3. These attractions increase in strength from methane to carbon dioxide to ammonia.

WRITE ABOUT SCIENCE

102. The higher the air pressure inside the ball, the higher the bounce. Assuming constant volume, the air pressure is directly proportional to the Kelvin temperature. Average temperature is higher in summer than in winter, which means the air pressure (and the height of the bounce) will be higher during the summer.

103. Answers will vary. The gas cylinders in CNG-fueled vehicles are designed to withstand high pressures. CNG dispensers must be gastight and capable of high compression.

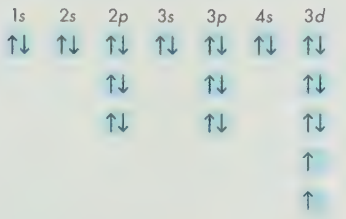
122. The motion of particles in a gas is constant, random, and rapid.

123. Gas pressure is the result of the collisions of gas particles with the container wall.



Cumulative Review

106. What is the mathematical relationship between the Kelvin and Celsius temperature scales?

***107.** A metal sample has a mass of 9.92 g and measures 4.50 cm × 1.30 cm × 1.60 mm. What is the density of the metal?

108. How many electrons, protons, and neutrons are there in an atom of lead-206?

109. Which element has the following electron configuration?

110. Which of these elements are metals?
a. arsenic **b.** tungsten **c.** xenon

111. Which element is most likely to form a compound with strontium?
a. neon **b.** tin **c.** selenium

112. Which compound contains at least one double bond?
a. H_2Se **b.** SO_2 **c.** PCl_3

***113.** Name each compound.
a. $SnBr_2$ **c.** $Mg(OH)_2$
b. $BaSO_4$ **d.** IF_5

114. An atom of lead has a mass 17.16 times greater than the mass of an atom of carbon-12. What is the molar mass of this isotope of lead?

***115.** Calculate the molar mass of each substance.
a. $Ca(CH_3CO_2)_2$ **c.** $C_{12}H_{22}O_{11}$
b. H_3PO_4 **d.** $Pb(NO_3)_2$

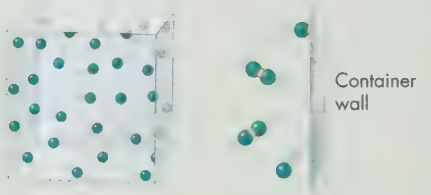
116. What is the significance of the volume 22.4 L?

***117.** Calculate the molecular formula of each of the following compounds.
a. The empirical formula is C_2H_4O, and the molar mass is 88 g.
b. The empirical formula is CH, and the molar mass is 104 g.
c. The molar mass is 90 g. The percent composition is 26.7% C, 71.1% O, and 2.2% H.

118. Calculate the percent composition of 2-propanol (C_3H_7OH).

119. What type of reaction is each of the following?
a. Calcium reacts with water to form calcium hydroxide and hydrogen gas.
b. Mercury and oxygen are prepared by heating mercury(II) oxide.

120. Write balanced equations for the following chemical reactions.
a. Tetraphosphorus decoxide reacts with water to form phosphoric acid.
b. Aluminum hydroxide and hydrogen sulfide form when aluminum sulfide reacts with water.



***121.** Aluminum oxide is formed from its elements.

$$Al(s) + O_2(g) \longrightarrow Al_2O_3(s)$$

a. Balance the equation.
b. How many grams of each reactant are needed to form 583 g $Al_2O_3(s)$?

122. Explain why a gas expands until it takes the shape and volume of its container.

123. Use the drawings to explain how gas pressure is produced.

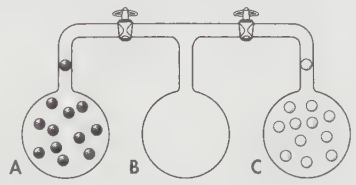
Standardized Test Prep for Indiana

Standard: C.5.1

Select the choice that best answers each question or completes each statement.

1. A gas in a balloon at constant pressure has a volume of 120.0 mL at −123°C. What is its volume at 27.0°C?
   (A) 60.0 mL **(C)** 26.5 mL
   (B) 240.0 mL **(D)** 546 mL
2. If the Kelvin temperature of a gas is tripled and the volume is doubled, the new pressure will be
   (A) 1/6 the original pressure.
   (B) 2/3 the original pressure.
   (C) 3/2 the original pressure.
   (D) 5 times the original pressure.
3. Which of these gases effuses fastest?
   (A) Cl_2 **(C)** NH_3
   (B) NO_2 **(D)** N_2
4. All the oxygen gas from a 10.0-L container at a pressure of 202 kPa is added to a 20.0-L container of hydrogen at a pressure of 505 kPa. After the transfer, what are the partial pressures of oxygen and hydrogen?
   (A) Oxygen is 101 kPa; hydrogen is 505 kPa.
   (B) Oxygen is 202 kPa; hydrogen is 505 kPa.
   (C) Oxygen is 101 kPa; hydrogen is 253 kPa.
   (D) Oxygen is 202 kPa; hydrogen is 253 kPa.
5. Which of the following changes would increase the pressure of a gas in a closed container?
   I. Part of the gas is removed.
   II. The container size is decreased.
   III. Temperature is increased.
   (A) I and II only
   (B) II and III only
   (C) I and III only
   (D) I, II, and III
6. A real gas behaves most nearly like an ideal gas
   (A) at high pressure and low temperature.
   (B) at low pressure and high temperature.
   (C) at low pressure and low temperature.
   (D) at high pressure and high temperature.



Use the graphs to answer Questions 7–10. A graph may be used once, more than once, or not at all.

Which graph shows each of the following?

7. directly proportional relationship
8. graph with slope = 0
9. inversely proportional relationship
10. graph with a constant slope

Use the drawing to answer Questions 11 and 12.

11. Bulb A and bulb C contain different gases. Bulb B contains no gas. If the valves between the bulbs are opened, how will the particles of gas be distributed when the system reaches equilibrium? Assume none of the particles are in the tubes that connect the bulbs.

Tips for Success

Constructing a Diagram If you are asked to draw a diagram, sketch lightly at first (so you can erase easily), or do a sketch on a separate piece of paper. Once you are sure of your answer, draw the final diagram.

12. Make a three-bulb drawing with 6 blue spheres in bulb A, 9 green spheres in bulb B, and 12 red spheres in bulb C. Then draw the setup to represent the distribution of gases after the valves are opened and the system reaches equilibrium.

Materials List

For the Student

Quick Lab, p 491
- shallow dish or Petri dish
- water
- paper clip
- rubber band (approximately 5 cm in diameter)
- 2 micropipets or droppers
- vegetable oil
- liquid dish detergent

Small-Scale Lab, p 508
- paper
- pencil
- ruler
- reaction surface
- water
- micropipet or dropper
- NaCl(s); Na_2CO_3(s); $NaHCO_3$(s); KCl(s); $MgSO_4$(s)
- table sugar
- cornstarch
- KI(s)
- aqueous solutions of HCl, H_2SO_4, HNO_3, CH_3COOH, NH_3, and NaOH
- rubbing alcohol
- distilled water
- various liquid foods

For the Teacher

Class Activity, p 497
- light bulb in a porcelain socket
- 9 V or lantern battery
- 2 copper metal strips
- lamp cord
- alligator clips
- 0.1*M* solutions of glucose, alanine, glycine, ascorbic acid, malonic acid, citric acid, acetic acid, hydrochloric acid
- 8 beakers

Teacher Demo, p 498
- $CoCl_2$ $6H_2O$ solution
- cotton swab
- white paper
- hot plate
- misting bottle
- water

Teacher Demo, p 506
- whole milk
- water
- beaker
- stirring rod
- projector or laser pointer

CHAPTER 15

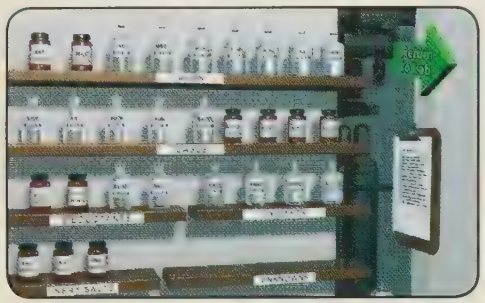
15 Water and Aqueous Systems

Water has many unique properties. In this chapter, you will learn about the interactions between water molecules.

INSIDE:

- **15.1** Water and Its Properties
- **15.2** Homogeneous Aqueous Systems
- **15.3** Heterogeneous Aqueous Systems

PearsonChem.com



What's Online

CHEM TUTOR Students access guided, step-by-step tutorials for calculating the percent by mass of water in a hydrate.

PROBLEM SETS Students can practice key problem-solving skills in an online problem set.

MATH HELP Identify the students that struggle with math by assigning an online math skills diagnostic test. These students can then improve and practice math skills by using the MathXL tutorial system.

VIRTUAL LAB Students go on an animated virtual lab tour in which various electrolytes are studied in a simulated laboratory environment.

KINETIC ART Students watch animations of selected figures from the chapter followed by questions to check for understanding.

CONCEPTS IN ACTION Students watch an overview of a key chapter concept using real-world contexts and concrete examples and analogies. Each activity includes an interactive animation followed by analysis questions.

IN ACADEMIC STANDARDS for SCIENCE

Nature of Science

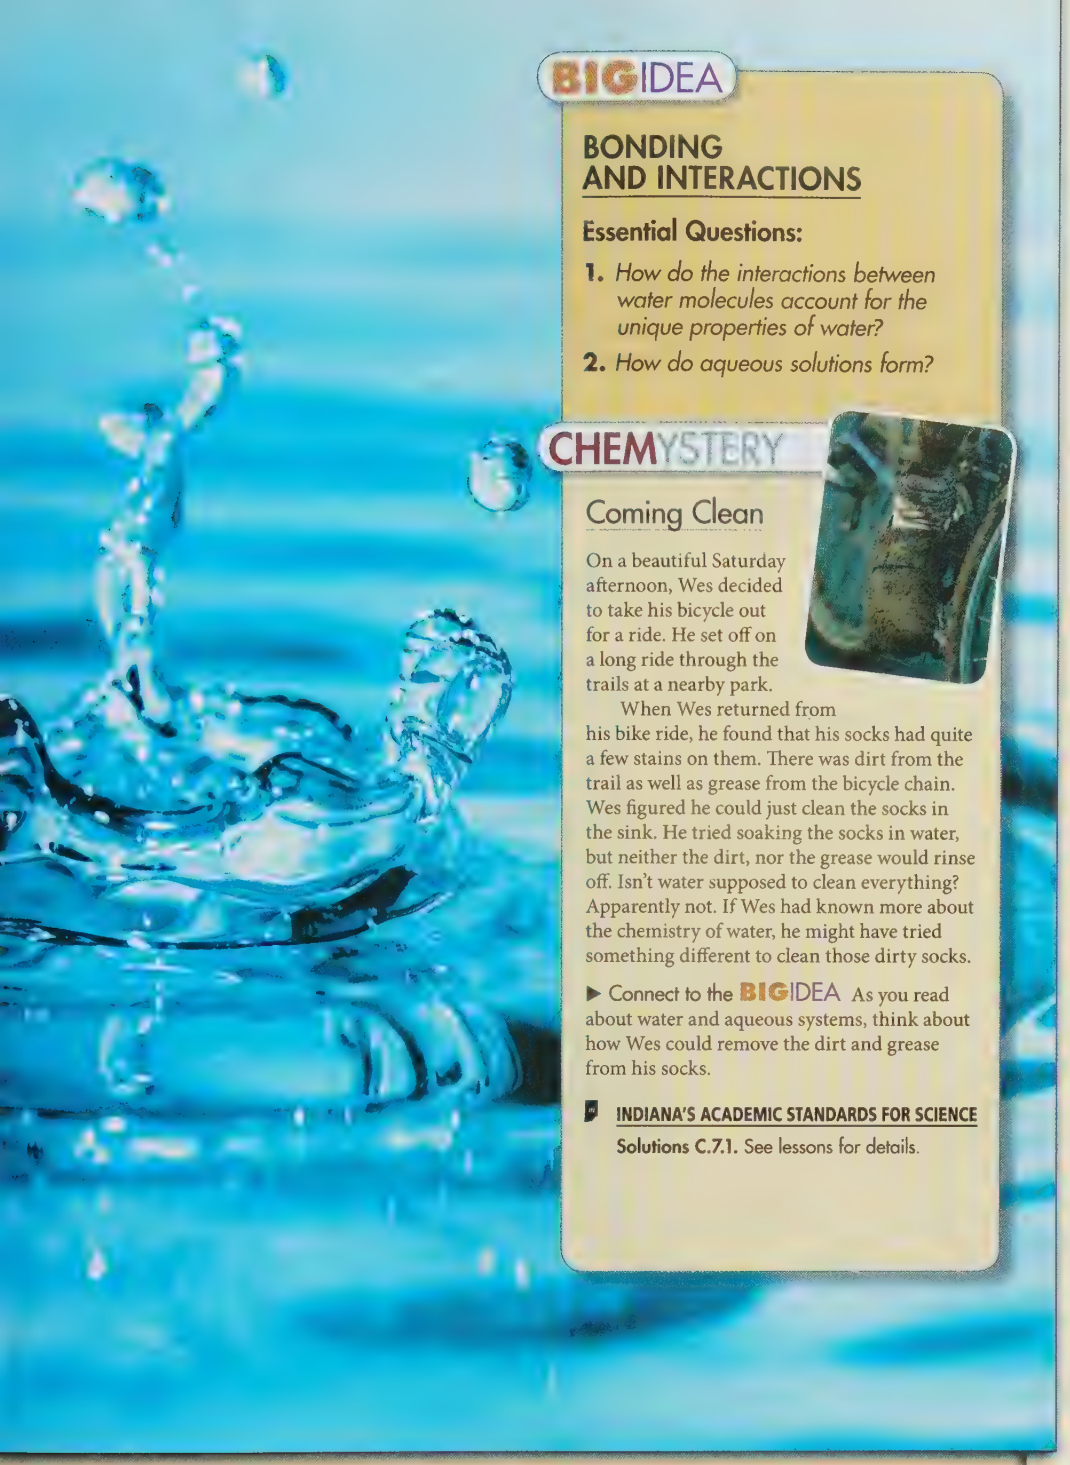
- Develop explanations based on reproducible data and observations gathered during laboratory investigations.

Standard 7: Solutions

C.7.1 Describe the composition and properties of types of solutions.

Focus on ELL

1 CONTENT AND LANGUAGE Write the words *homogeneous*, *heterogeneous*, and *aqueous* on the board. Assign students to three groups. Assign each group of students one of the words, and ask them to brainstorm the meaning of the prefix of their word. Then have each group complete a Frayer model diagram for the word, with a definition, characteristics, an example, and a nonexample. Have each group teach the word to the class.



BEGINNING

LOW Draw a symbol to represent the meaning of the prefix.

HIGH Use a bilingual dictionary or glossary to find any cognates for the prefix.

INTERMEDIATE: LOW/HIGH List other words that use the same prefix.

ADVANCED: LOW/HIGH After the class presentations, have students predict the meaning of the lesson titles *Homogeneous Aqueous Systems* and *Heterogeneous Aqueous Systems*.

BIGIDEA

BONDING AND INTERACTIONS

Essential Questions:

1. *How do the interactions between water molecules account for the unique properties of water?*
2. *How do aqueous solutions form?*

CHEMYSTERY

Coming Clean

On a beautiful Saturday afternoon, Wes decided to take his bicycle out for a ride. He set off on a long ride through the trails at a nearby park.

When Wes returned from his bike ride, he found that his socks had quite a few stains on them. There was dirt from the trail as well as grease from the bicycle chain. Wes figured he could just clean the socks in the sink. He tried soaking the socks in water, but neither the dirt, nor the grease would rinse off. Isn't water supposed to clean everything? Apparently not. If Wes had known more about the chemistry of water, he might have tried something different to clean those dirty socks.

▶ Connect to the BIGIDEA As you read about water and aqueous systems, think about how Wes could remove the dirt and grease from his socks.

INDIANA'S ACADEMIC STANDARDS FOR SCIENCE

Solutions C.7.1. See lessons for details.

Introduce the Chapter

IDENTIFYING MISCONCEPTIONS Students may think a solution is always tiny bits of a solute floating in a solvent that is continuous; that is, the solvent is not made of individual particles. As a result, they may think any solute will dissolve in water. Use the following activity to help them realize that water will not dissolve all substances.

Activity *You will need glass beakers, stirring rods, water, and various substances that are or are not soluble in water.* **Ask** Do you think all these substances will dissolve in water? *(Answers will vary.)* Have students predict whether each substance will dissolve in water at room temperature. Then have student volunteers try to dissolve the substances in water. Conclude by stating that water's properties cause it to dissolve some substances but not others. Explain that students will learn the difference as they study the chapter.

UbD

Understanding by Design

Students are building toward the ability to predict how particles bond and interact by understanding how the properties of water and aqueous solutions are affected by interactions among water molecules.

PERFORMANCE GOALS At the end of Chapter 15, students will be able to answer the essential questions by applying their knowledge of water and aqueous solutions. Students will also be able to calculate the percent by mass of water in a hydrate.

ESSENTIAL QUESTIONS Read the essential questions aloud. **Ask** What is the structure of a water molecule? *(two hydrogen atoms covalently bonded to an oxygen atom)* **Ask** What are some properties of water? *(Sample answers: It forms spherical drops. It can dissolve many substances. It has three states of matter.)* **Ask** How do you think a water molecule's structure relates to water's ability to form spherical drops? How do you think its structure relates to water's ability to dissolve many substances? *(Engage students in a discussion of reasonable answers.)*

BIGIDEA Use the photo of water drops to help students connect to the concepts they will learn in this chapter. Activate prior knowledge by reviewing the covalent bonding in a water molecule. **Ask** Why do you think people use water to wash hands, dishes, and laundry? *(Sample answers: Water is abundant on Earth. Water often cleans things well.)* Point out that the covalent bonding in a water molecule affects the way it interacts with other substances.

CHEMYSTERY Have students read over the CHEMystery. Connect the CHEMystery to the Big Idea of bonding and interactions by asking students to think about how the bonding in a water molecule might affect the ability of water to remove the dirt and grease from Wes's socks. Challenge students to predict what Wes could use to clean his dirty socks. Have students write their predictions on notecards. As a hint, suggest that students think about what they use at home when they wash their hands, dishes, or laundry.

LESSON 15.1

Key Objectives

15.1.1 IDENTIFY the factor that causes the high surface tension, low vapor pressure, and high boiling point of water.

15.1.2 DESCRIBE the structure of ice.

Additional Resources

- Reading and Study Workbook, Lesson 15.1
- Probeware Laboratory Manual, Core Teaching Resources, Lesson 15.1

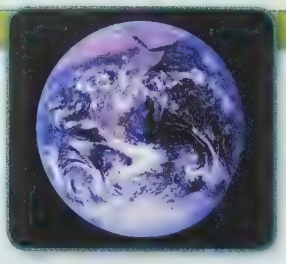
PearsonChem.com

Engage

CHEMISTRY & YOU Have students study the photograph and read the text. **Ask** What are the white swirls in the photo? *(clouds)* **Ask** How are the white swirls relevant to the subject matter of this chapter? *(Clouds form when water vapor in the atmosphere condenses into tiny liquid droplets.)*

Activate Prior Knowledge

Before students begin to read this chapter, review the concepts of polarity and hydrogen bonding. Remind students that water is a liquid rather than a gas at room temperature because of the strong hydrogen bonding between water molecules.



IN ACADEMIC STANDARDS for SCIENCE

C.3.3 Compare and contrast ionic, covalent network, metallic and polar and non-polar molecular crystals with respect to constituent particles, strength of bonds, melting and boiling points, and conductivity; provide examples of each type.

C.7.1 Describe the composition and properties of types of solutions.

15.1 Water and Its Properties

C.3.3 Chemical bonds and intermolecular attractions; **C.7.1** Composition and properties of solutions

CHEMISTRY & YOU

Q: *What properties of water make it essential to life on Earth?* When the *Apollo 8* astronauts first saw their home planet from a distance of thousands of kilometers, they called it the big blue marble. Water covers about three quarters of Earth's surface. In addition to making up Earth's oceans, water forms the polar ice caps and cycles through the atmosphere. All known life forms, including the penguin in Figure 15.1, are made mostly of water.

Key Questions

What factor causes the high surface tension, low vapor pressure, and high boiling point of water?

How can you describe the structure of ice?

Vocabulary

- surface tension
- surfactant

Figure 15.1 Water Is Vital to Life The oceans supply penguins with an abundant supply of food.

Water in the Liquid State

What factor causes the high surface tension, low vapor pressure, and high boiling point of water?

You couldn't live without water, nor could all the plants and animals that share space on the "big blue marble." Besides the water visible on Earth's surface, immense reserves of water exist deep underground. Water in the form of ice and snow dominates the polar regions of Earth. Water vapor from the evaporation of surface water and from steam spouted from geysers and volcanoes is always present in Earth's atmosphere.

Recall that water, H_2O, is a simple molecule consisting of three atoms. The oxygen atom forms a covalent bond with each of the hydrogen atoms. Oxygen has a greater electronegativity than hydrogen, so the oxygen atom attracts the electron pair of the covalent O—H bond to a greater extent than the hydrogen atom. Thus, the O—H bond is highly polar. As a result, the oxygen atom acquires a partial negative charge ($\delta-$). The less electronegative hydrogen atoms acquire partial positive charges ($\delta+$).

Focus on ELL

1 CONTENT AND LANGUAGE Create a KWL chart with the students, beginning with the things they know about water in all of its forms. Ask students to describe personal experiences they have had with liquid water or ice such as swimming, ice-skating, and seeing fog.

2 FRONTLOAD THE LESSON Display pictures of the planets of our solar system, and encourage students to share what they know about each. Point out that only Earth has the characteristic blue hue that indicates the presence of surface water. Explain that the presence of water on Earth is one of the primary reasons that Earth can support life. Tell students to make note of each of water's life-sustaining properties that they will read about in the lesson.

3 COMPREHENSIBLE INPUT Have students view the Kinetic Art animation on hydrogen bonding. Use a role-playing activity to model the effect of adding a surfactant to water to demonstrate how surfactant molecules limit the ability of water molecules to hydrogen bond.

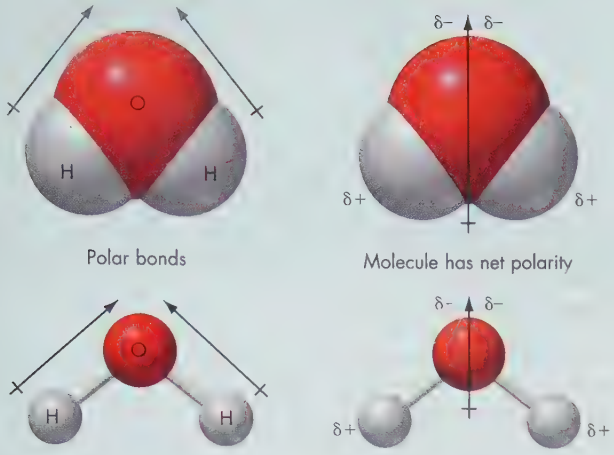


Figure 15.2 Polarity of H_2O
In a water molecule, the bond polarities are equal, but the two poles do not cancel each other because a water molecule is bent. The molecule as a whole is polar.
Apply Concepts ***Which element in water has the higher electronegativity?***

How do the polarities of the two O—H bonds affect the polarity of the molecule? The shape of the molecule is the determining factor. The bond angle of the water molecule is approximately 105°, which gives the molecule a bent shape. The two O—H bond polarities do not cancel, so the water molecule as a whole is polar. The net polarity of the water molecule is illustrated in Figure 15.2.

In general, polar molecules are attracted to one another by dipole interactions. The negative end of one molecule attracts the positive end of another molecule. However, in water, this attraction results in hydrogen bonding, as illustrated in Figure 15.3. Recall that hydrogen bonds are attractive forces that arise when a hydrogen atom is covalently bonded to a very electronegative atom and also weakly bonded to an unshared electron pair of another electronegative atom. Hydrogen bonds are not as strong as covalent bonds, but they are stronger than other intermolecular forces. **Many unique and important properties of water—including its high surface tension, low vapor pressure, and high boiling point—result from hydrogen bonding.**

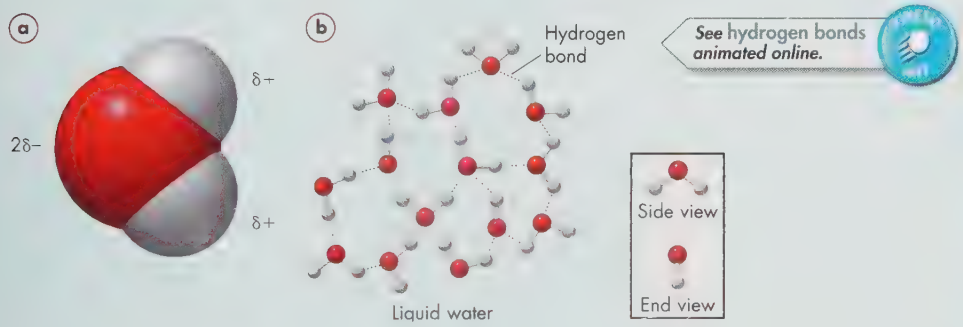

Figure 15.3 Hydrogen Bonding in Water
The polarity of the water molecule results in hydrogen bonding. **a.** The oxygen atom has a partial negative charge. Each hydrogen atom has a partial positive charge. **b.** Hydrogen bonds form between the hydrogen atom of one water molecule and the oxygen atom of an adjacent water molecule.
Infer ***To form a hydrogen bond, what must be true about hydrogen and the element to which it is hydrogen bonded?***

See hydrogen bonds *animated online.*

Professional Development Note

Water Worth Drinking

The year 2009 marked the 35th year of public health protection under the Safe Drinking Water Act. The Act, passed in 1974 and amended in 1986 and 1996, gives the Environmental Protection Agency (EPA) the authority to set drinking water standards. Drinking water standards apply to public water systems.

Standards for safety are constantly being examined by the EPA and change as new data become available. These standards set upper limits on potentially harmful substances that could be present in water. These substances include pesticides, household chemicals, and various microorganisms. Some microorganisms occur naturally in drinking water sources, but others indicate contamination by sewage or animal wastes. Two microorganisms are routinely monitored: coliform bacteria and the *Cryptosporidium* parasite. Both organisms can cause gastrointestinal disorders ranging from mild to severe. Cryptosporidiosis is potentially fatal for patients with compromised immune systems.

Foundations for Reading

BUILD VOCABULARY The word *tension* comes from the Latin *tendere*, which means "to stretch." Thus, surface tension causes the surface of a liquid to appear stretched and taut. Have students use the derivation of *tension* to explain the expression *nervous tension. (a condition of stress or tautness in an individual, brought about by some external cause)*

READING STRATEGY Have students preview the figures and read the related captions. Encourage students to use the caption information to predict the answers to any questions associated with the figures.

Explain

Water in the Liquid State

START A CONVERSATION Tell students that, although three-quarters of Earth's surface is water, only a small fraction of it can be used for drinking. The majority of Earth's surface water is in the oceans and contains too high a concentration of salts for the human body to tolerate.

USE VISUALS Have students study Figures 15.2 and 15.3. **Ask** What is meant by the term *polarity*? *(Polarity refers to the net molecular dipole resulting from electronegativity differences between covalently bonded atoms.)* **Ask** What element in a water molecule has a partial negative charge? *(the oxygen atom)* **Ask** What element has a partial positive charge? *(the hydrogen atoms)* **Ask** Predict the type of substances you would expect to dissolve in water. *(polar substances, ionic compounds)*

APPLY CONCEPTS Write the structural formula of water on the board, or hold up a model of a water molecule. Have students use Table 6.2 on page 181 to find and compare the electronegativity of oxygen and hydrogen. Use VSEPR theory and the model to show students how the oxygen's non-bonding electron pairs reduce the bond angle in a water molecule to 105°. Point out how the net molecular dipole and hydrogen bonding properties of water are due to the large electronegativity difference between hydrogen and oxygen. Note that hydrogen bonding contributes to water's unusually low vapor pressure and high surface tension.

Answers

FIGURE 15.2 oxygen

FIGURE 15.3 The hydrogen atom must be covalently bonded to a very electronegative atom with one or more lone pairs of electrons.

Explain

USE VISUALS Direct students' attention to Figure 15.4. To help explain why liquid water assumes a spherical shape on many surfaces, explain that nature tends to find the path of least resistance. Guide students to understand that a spherical shape provides the minimum surface area for a given volume; since moving molecules takes work, molecules expend the least energy possible to move into a spherical arrangement while maximizing their interactions with one another in the bulk liquid. This energy efficiency creates the surface tension. Explain that in order to produce any other shape, more work would have to be done. So, the work "saved" is the surface tension.

USE AN ANALOGY Convey that the *skin-like* qualities of water are due to an exceptionally high surface tension that is created by an extensive network of hydrogen bonds. As an analogy, describe the following scene. A crowd of autograph seekers surrounds a celebrity. As each person approaches as closely as possible, an impenetrable circular barrier forms. This barrier will remain intact as long as there is a net attraction toward the circle's center. The process is dynamic. As one person wiggles closer to the celebrity, another is forced to retreat, but the overall shape does not change. Similarly, within a drop of water, attractions between individual molecules may shift, but the overall shape remains constant as molecules continue to be drawn toward a central focal point.

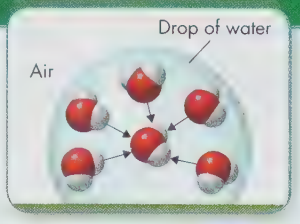

Figure 15.4
Surface Tension of Water
Water forms nearly spherical drops on a leaf. Water molecules at the surface of the water drop cannot form hydrogen bonds with molecules in the air, so they are drawn into the body of the liquid.

Surface Tension Have you ever seen a glass so filled with water that the water surface is not flat but bulges above the rim? Have you noticed that water forms nearly spherical droplets at the end of a medicine dropper or on a leaf, as shown in Figure 15.4? The surface of water acts like a skin. This property of water's surface is explained by the ability of water molecules to form hydrogen bonds. The water molecules within the body of the liquid form hydrogen bonds with other molecules that surround them on all sides. The attractive forces on each of these molecules are balanced. However, water molecules at the surface of the liquid experience an unbalanced attraction. You can see in Figure 15.4 that the water molecules are hydrogen bonded on only the inside of the drop. As a result, water molecules at the surface tend to be drawn inward. The inward force, or pull, that tends to minimize the surface area of a liquid is called **surface tension.**

All liquids have a surface tension, but water's surface tension is higher than most. This is why, on some surfaces, water tends to bead up rather than spread out. The surface tension of water tends to hold a drop of liquid in a spherical shape. For example, you may notice that water tends to form beads on the surface of a newly waxed car. The wax molecules are nonpolar, so there is little or no attraction between the wax molecules and the polar water molecules. The drops are not perfect spheres because the force of gravity tends to pull them down, causing them to flatten.

It is possible to decrease the surface tension of water by adding a surfactant. A **surfactant** is any substance that interferes with the hydrogen bonding between water molecules and thereby reduces surface tension. Soaps and detergents are surfactants. Adding a detergent to beads of water on a greasy surface reduces surface tension, causing the beads of water to collapse and spread out, as shown in Figure 15.5.

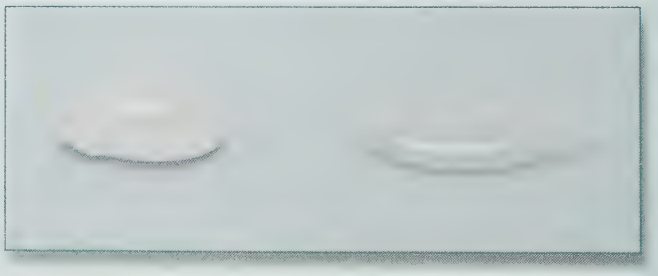

Figure 15.5 Effect of a Surfactant
Water drops bead up on some surfaces. When detergent, a surfactant, is added to water, the drop spreads out.
Compare *Which liquid drop has a higher surface tension?*

Differentiated Instruction

L3 ADVANCED STUDENTS Explain that the structure of ice was determined using X-ray diffraction, a method that was also used by Rosalind Franklin in her work with DNA. This work contributed to the discovery of the helical structure of DNA by James Watson and Francis Crick. Have students research how X-ray diffraction is used to determine the structure of a substance.

L1 STRUGGLING STUDENTS Have students use prior knowledge and create a visual of the water cycle. Ask them to explain changes of state. Have students refer to their diagram as you teach the more unfamiliar properties of water.

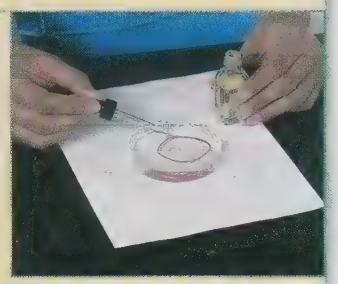
LPR LESS PROFICIENT READERS Allow students to use food coloring, cotton swabs, and a protractor to visually grasp the concept of polarity and bond angle in water molecules. Students can use the food coloring to stain one end of the cotton swab green and the other end red to represent negative and positive charge and then correctly orient their cotton swabs to form a 105° angle.

Vapor Pressure Hydrogen bonding between water molecules also explains water's unusually low vapor pressure. Remember that the vapor pressure of a liquid is the result of molecules escaping from the surface of the liquid and entering the vapor phase. An extensive network of hydrogen bonds holds the molecules in liquid water to one another. These hydrogen bonds must be broken before water changes from the liquid to the vapor state, so the tendency of these molecules to escape is low and evaporation is slow. Imagine what would happen if it were not. All the lakes and oceans, with their large surface areas, would rapidly evaporate!

Boiling Point Molecular compounds of low molar mass are usually gases or liquids with low boiling points at normal atmospheric pressure. Ammonia (NH_3), a molecular compound, has a molar mass of 17.0 g/mol and boils at about −33°C. Water has a molar mass of 18.0 g/mol, but it has a boiling point of 100°C. The difference between the boiling points of these two compounds is due to hydrogen bonding, which is more extensive in water than in ammonia. It takes much more heat to disrupt the attractions between water molecules than those between ammonia molecules. If the hydrogen bonding in water were as weak as it is in ammonia, water would be a gas at the usual temperatures found on Earth.

READING SUPPORT

Build Reading Skills:
Inference If water molecules did not form hydrogen bonds with each other, water would have a much lower boiling point. ***What do you think this would mean for life as we know it?***



Quick Lab

Surface Tension

Purpose To observe an unusual surface property of water that results from hydrogen bonding

Materials
- shallow dish or petri dish
- water
- paper clip
- rubber band, approximately 5 cm in diameter
- micropipets or droppers (2)
- vegetable oil
- liquid dish detergent

Procedure

1. Thoroughly clean and dry the dish.
2. Fill the dish almost full with water. Dry your hands.
3. Being careful not to break the surface, gently place the paper clip on the water. Observe what happens.
4. Repeat Steps 1 and 2.
5. Gently place the open rubber band on the water.
6. Slowly add the vegetable oil drop by drop onto the water encircled by the rubber band until that water is covered with a layer of oil. Observe for 15 seconds.
7. Allow one drop of dish detergent to fall onto the center of the oil layer. Observe the system for 15 seconds.

Analyze and Conclude

1. **Observe** What happened to the paper clip in Step 3? Why?
2. **Predict** If a paper clip becomes wet, does it float? Explain your answer.
3. **Observe** What shape did the rubber band take when the water inside it was covered with oil? Why did it take the observed shape?
4. **Describe** What happened when a drop of dish detergent was placed onto the layer of oil?

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the lab. Make sure each group has ELLs of varied language proficiencies so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Allow students to draw a picture of their observations.

INTERMEDIATE: LOW/HIGH Paraphrase the procedure and the Analyze and Conclude questions for students.

ADVANCED: LOW/HIGH Have these students assist those with lower English proficiencies to complete the procedure and answer the questions.

Misconception Alert

Students may believe that the surface of a volume of water contains a different kind of water molecule than its interior. Remind students that surface tension still exists even after you mix the water sample to redistribute the molecules.

Explore

QuickLab

OBJECTIVE After completing this activity, students will be able to identify a property of water that results from hydrogen bonding and will be able to describe the effect of a surfactant on surface tension.

SKILLS FOCUS Observing, inferring, drawing conclusions

PREP TIME 10 minutes

CLASS TIME 20 minutes

ADVANCE PREPARATION Gather paper clips, rubber bands, detergent, and vegetable oil.

TEACHING TIPS Have students dry their hands before touching the paper clips.

EXPECTED OUTCOME The paper clip floats. The rubber band takes on a circular shape when filled with oil. Detergent destroys the surface tension and causes the rubber band to return to its original, noncircular shape.

ANALYZE AND CONCLUDE

1. The paper clip floated. The surface tension of the water supported the paper clip.
2. No. The surface tension is broken, and the paper clip sinks because it is made of a metal that has a greater density than water.
3. The rubber band took a circular shape. The surface tension of the surrounding water pulling the rubber band radially outward was not balanced by the surface tension of the oil.
4. The oil layer was broken, and the rubber band returned to its original shape.

FOR ENRICHMENT Explain that some insects, such as a water strider, depend on the surface tension of water for moving around and capturing food. Tell students that detergents are increasingly found as pollutants in bodies of water in nature. Have students design an experiment to determine the concentration of detergent at which water can no longer support the weight of a water strider.

Answers

FIGURE 15.5 The water droplet on the left has a higher surface tension.

READING SUPPORT Sample Answer: There would be less water in the liquid state and more water in the gaseous state.

Explain

Water in the Solid State

USE VISUALS Direct students' attention to Table 15.1. **Ask** What relation do you notice between temperature and density? *(The density of liquid water increases over most of the range of decreasing temperature.)* **Ask** Why does this trend not continue below 4°C? *(Below 4°C, the kinetic energy of the molecules is insufficient to overcome hydrogen bonding, which holds the water molecules in fixed positions.)* If students have difficulty discerning the pattern, use the overhead and plot the data in the table on a coordinate grid; place temperature on the *x*-axis and density on the *y*-axis.

CRITICAL THINKING Have students explain why ice, which has a smaller mass per volume ratio than liquid water, results in a lower relative density. *(Density is based on mass per volume; the substance with the smaller mass per volume ratio has the lower density.)*

Misconception Alert

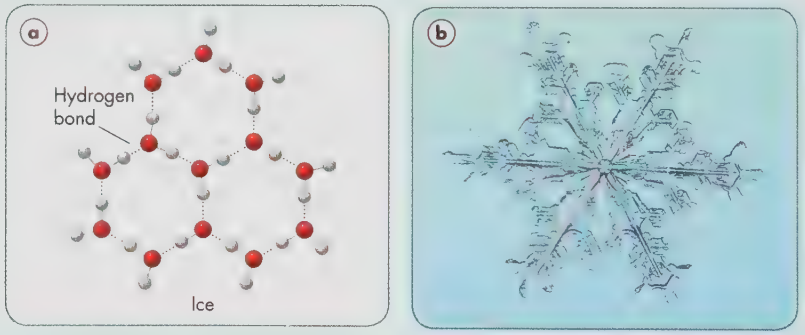
Make sure students understand that hydrogen bonding always involves hydrogen, but it is not a type of chemical bond. Rather, it explains a type of intermolecular attractive force. Explain that polarity is a type of intermolecular force—a force that occurs between molecules. Covalent bonding—the bond between hydrogen and oxygen in a water molecule—is a type of intramolecular force.

Water in the Solid State

How can you describe the structure of ice?

You have seen that water in the liquid state exhibits some unique properties. The same is true for water in the solid state. For example, ice cubes float in your glass of iced tea because solid water has a lower density than liquid water. This situation is not usual for liquids. As a typical liquid cools, it begins to contract and its density increases gradually. The density increases because the molecules of the liquid move closer together so that a given volume of the liquid contains more molecules and thus more mass. If the cooling continues, the liquid eventually solidifies with a density greater than the density of the liquid. A typical solid sinks in its own liquid because the density of the solid is greater than that of the corresponding liquid.

Table 15.1



Density of Liquid Water and Ice

Temperature (°C)	Density (g/cm^3)
100 (liquid water)	0.9584
50	0.9881
25	0.9971
10	0.9997
4	1.0000
0 (liquid water)	0.9998
0 (ice)	0.9168

As water begins to cool, it behaves initially like a typical liquid. It contracts slightly and its density gradually increases, as shown in Table 15.1. Notice that at 4°C, the density of water is at its maximum of 1.0000 g/cm^3. When the temperature of the water falls below 4°C, the density of water actually starts to decrease. Below 4°C, water no longer behaves like a typical liquid. Ice, which forms at 0°C, has about a 10 percent lower density than liquid water at 0°C. You may have noticed that ice begins to form at the surface of a pond when the temperature reaches 0°C, but the ice does not sink. It floats at the surface, making ice skating and ice fishing possible. Ice is one of only a few solids that floats in its own liquid.

Why is ice less dense than liquid water? As you can see in Figure 15.6, hydrogen bonds hold the water molecules in place in the solid phase. **The structure of ice is a regular open framework of water molecules in a hexagonal arrangement.** When ice melts, the framework collapses. Looking back at Figure 15.3, you can see that the water molecules pack closer together in liquid water, making it more dense than ice.

Figure 15.6 Structure of Ice
The unique properties of ice are a result of hydrogen bonding. **a.** Extensive hydrogen bonding in ice holds the water molecules farther apart in a more ordered arrangement than in liquid water. **b.** The hexagonal symmetry of a snowflake reflects the structure of the ice crystal.
Compare and Contrast ***How are the structures of liquid water (shown in Figure 15.3) and ice similar? How are they different?***

UbD Check for Understanding

The Essential Question **How do the interactions between water molecules account for the unique properties of water?**

Assess students' knowledge about the importance of hydrogen bonding in water by asking them to write a paragraph that explains how hydrogen bonding is responsible for one of the following properties of water: high surface tension, high boiling point, low vapor pressure, or high melting point.

ADJUST INSTRUCTION If students are having difficulty with this exercise, have them reread the portion of this lesson associated with their chosen property. Then provide students with the opportunity to revise their paragraphs.

The fact that ice floats has important consequences for organisms. A layer of ice on the top of a body of water, such as the one shown in Figure 15.7, acts as an insulator for the water beneath, preventing the water from freezing solid except under extreme conditions. The liquid water at the bottom of an otherwise frozen body of water is warmer than 0°C, so fish and other aquatic life are better able to survive. If ice were denser than liquid water, bodies of water would tend to freeze solid during the winter months, destroying many types of organisms.

Ice melts at 0°C, which is a high melting temperature for a molecule with such a low molar mass. A considerable amount of energy is required to return water molecules in the solid state to the liquid state. The heat absorbed when 1 g of water at 0°C changes from a solid to a liquid is 334 J. This heat is the same amount of energy that is needed to raise the temperature of 1 g of liquid water from 0°C to 80°C.

CHEMISTRY & YOU

Q: *What properties of water that result from hydrogen bonding make it essential to life on Earth?*

Figure 15.7 Ice Floats in Liquid Water Many organisms that live in water would not survive if ice were more dense than liquid water.

15.1 LessonCheck

1. **Review** What causes the high surface tension, low vapor pressure, and high boiling point of water?
2. **Describe** How are water molecules arranged in ice?
3. **Explain** Why does water form spherical drops on some surfaces?
4. **Relate Cause and Effect** What effect does a surfactant have on the surface tension of water?
5. **Infer** Water (H_2O) and methane (CH_4) have similar molar masses. Methane changes from a liquid to a gas at −161°C. Water becomes a gas at 100°C. What could account for the difference?
6. **Apply Concepts** What causes water pipes to break in freezing weather?

BIG IDEA BONDING AND INTERACTIONS

7. Describe how hydrogen bonding accounts for the properties of water.

Lesson Check Answers

1. Water molecules are hydrogen bonded to each other but not to air molecules. Net attraction is inward, minimizing the water surface area. Hydrogen bonding makes it more difficult for water molecules to escape from the liquid phase to the vapor phase.
2. Ice has a honeycomb-like structure of water molecules.
3. The surface tension of a liquid tends to hold a drop of liquid in a spherical shape.
4. Surfactants lower the surface tension of water by interfering with hydrogen bonding.
5. Water has intermolecular hydrogen bonding between its molecules; methane does not.
6. Water expands as it freezes.
7. Water molecules at the surface of a water drop are drawn into the body of the liquid producing water's unusually high surface tension. Hydrogen bonds also hold water molecules to one another resulting in water's unusually low vapor pressure.

CHEMISTRY & YOU Ice is less dense than liquid water because of hydrogen bonding. As a result, ice floats on the surface of water providing a layer of insulation for the water beneath. Many organisms are able to survive underwater in the winter because the water is not frozen.

Extend

Connect to SOCIAL STUDIES

Have students compare areas of population density and the distribution of water. Provide students with two different maps. One map should show the locations of cities and towns. The other should be a regional contour map showing water courses, rivers, lakes, and reservoirs. Have students determine why most large cities or historical sites are located near water sources, and have them explain the effects when such places are not near water. Ask students to examine the vast irrigation networks and water channels that crisscross the nation's agricultural areas. Have students determine the ways in which water is transported to arid regions and to population centers with insufficient fresh water.

Evaluate

Informal Assessment

Ask Why is the surface tension of water so high compared to that of other liquids? *(Water molecules form a large number of hydrogen bonds, in addition to dipole-dipole forces between molecules.)* **Ask** Why does water form a meniscus in a narrow tube? *(Water molecules have a greater attraction to the molecules on the surface of the glass than they do to each other.)* Then have students complete the 15.1 Lesson Check.

Reteach

Have students explain the property of water that allows ice to float in its liquid phase. *(Ice has a lower density than liquid water. Because there is more space between water molecules in the solid state than the liquid state, there are fewer molecules in any given volume. Less mass per volume results in a lower relative density of ice as compared to water.)*

Answers

FIGURE 15.6 There are two hydrogen atoms attached to one oxygen atom in both structures. The molecules in liquid water are further apart and have a less ordered arrangement than ice.

LESSON 15.2

Key Objectives

15.2.1 IDENTIFY the types of substances that dissolve most readily in water.

15.2.2 EXPLAIN why all ionic compounds are electrolytes.

15.2.3 EXPLAIN why hydrates easily lose and regain water.

CHEMISTRY & YOU Have students study the photograph and read the text. **Ask** What is it about the pickle that allows it to produce light? *(It conducts electricity.)* **Ask** What are some other materials that conduct electricity? *(metals and ionic solutions)*

Access Prior Knowledge

Explain that in this lesson students will rely on their understanding of polarity, ionic compounds, covalent compounds, and molar mass to understand the concepts of aqueous systems.

IN ACADEMIC STANDARDS for SCIENCE

C.7.1 Describe the composition and properties of types of solutions.

15.2 Homogeneous Aqueous Systems

C.7.1 Composition and properties of solutions

CHEMISTRY & YOU

Q: *How can you make a pickle glow?* Is it possible to read by the light of a glowing pickle? Although it sounds absurd, an ordinary dill pickle from the deli can be a source of light! Metal forks are inserted into the ends of the pickle and connected to a source of alternating electric current. After a time, during which the pickle becomes hot and produces steam, the pickle begins to glow. The mechanism by which the light is generated is not fully understood, but it is clear that conduction of electric current by the pickle is an important factor.

Key Questions

What types of substances dissolve most readily in water?

Why are all ionic compounds electrolytes?

Why do hydrates easily lose and regain water?

Vocabulary

- aqueous solution • solvent
- solute • solvation
- electrolyte • nonelectrolyte
- strong electrolyte
- weak electrolyte
- water of hydration • hydrate
- anhydrous • effloresce
- hygroscopic • desiccant
- deliquescent

Solutions

What types of substances dissolve most readily in water?

Water dissolves so many of the substances that it comes in contact with that you won't find chemically pure water in nature. Even the tap water you drink is a solution that contains varying amounts of dissolved minerals and gases. An **aqueous solution** is water that contains dissolved substances.

Solvents and Solutes In a solution, the dissolving medium is the **solvent.** The dissolved particles in a solution are the **solute.** A solvent dissolves the solute, and the solute becomes dispersed in the solvent. Solvents and solutes may be gases, liquids, or solids.

Recall that solutions are homogeneous mixtures. They are also stable mixtures. For example, sodium chloride (NaCl) does not settle out when its solutions are allowed to stand, provided other conditions, such as temperature, remain constant. Solute particles can be atoms, ions, or molecules, and their average diameters are usually less than 1 nm (10^{-9} m). Therefore, if you filter a solution through filter paper, both the solute and the solvent pass through the filter.

Substances that dissolve most readily in water include ionic compounds and polar covalent compounds. Nonpolar covalent compounds, such as methane, and compounds found in oil, grease, and gasoline, do not dissolve in water. However, oil and grease will dissolve in gasoline. To understand this difference, you must know more about the structures of the solvent and the solute and what attractions exist between them.

Focus on ELL

1 CONTENT AND LANGUAGE Have small groups of students create flashcards with the vocabulary terms by writing each term on one side of a card and a definition and visual on the other. Allow students with limited English to use their native languages for support.

2 FRONTLOAD THE LESSON Have students discuss aqueous systems they have made or observed at home. Ask students to state whether the items in these aqueous systems are solids, liquids, and/or gases.

3 COMPREHENSIBLE INPUT Have students bring in a grocery item that they believe to be an aqueous system. Write the definition for *homogeneous aqueous system* on the board, and have students place their items on a specified desk if they can defend that their items satisfy the definition.

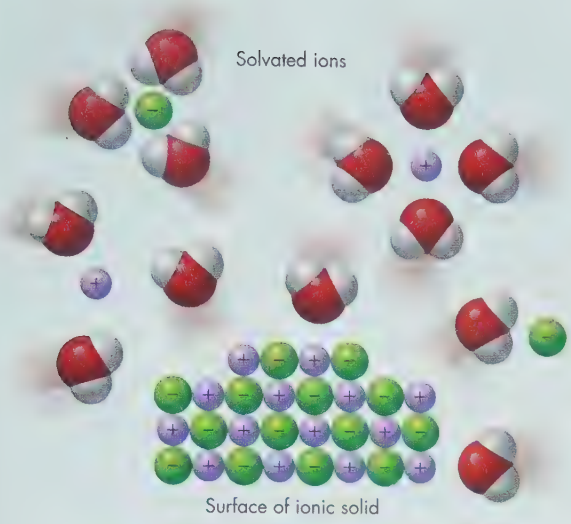

Figure 15.8 Solvation of an Ionic Solid
When an ionic solid dissolves, the ions become solvated, or surrounded by solvent molecules.
Infer *Why do the water molecules orient themselves differently around the anions and the cations?*

See solvation animated online.

The Solution Process Water molecules are in continuous motion because they have kinetic energy. When a crystal of sodium chloride is placed in water, the water molecules collide with the crystal. Remember that a water molecule is polar, with a partial negative charge on the oxygen atom and partial positive charges on the hydrogen atoms. The polar solvent molecules (H_2O) attract the solute ions (Na^+, Cl^-). As individual solute ions break away from the crystal, the negatively and positively charged ions become surrounded by solvent molecules and the ionic crystal dissolves. The process by which the positive and negative ions of an ionic solid become surrounded by solvent molecules is called **solvation.** Figure 15.8 shows a model of the solvation of an ionic solid such as sodium chloride.

In some ionic compounds, the attractions among the ions in the crystals are stronger than the attractions exerted by water. These compounds cannot be solvated to any significant extent and are therefore nearly insoluble. Barium sulfate ($BaSO_4$) and calcium carbonate ($CaCO_3$) are examples of nearly insoluble ionic compounds.

Figure 15.9 shows that oil and water do not mix. What about oil in gasoline? Both oil and gasoline are composed of nonpolar molecules. The attractive forces that hold two molecules in oil together are similar in magnitude to the forces that hold two molecules in gasoline together. Molecules in oil can easily separate and replace molecules in gasoline to form a solution. As a rule, polar solvents such as water dissolve ionic compounds and polar compounds; nonpolar solvents such as gasoline dissolve nonpolar compounds. This relationship can be summed up in the expression "like dissolves like."

Figure 15.9 Oil and Water
Oil and water do not mix. Oil is less dense than water, so it floats on top. The colors result from the bending of light rays by the thin film of oil.

Differentiated Instruction

LPR LESS PROFICIENT READERS Have students preview the section by looking for vocabulary and other unfamiliar terms. Encourage students to write the terms, with phonetic respellings and definitions, in their notebooks.

L1 SPECIAL NEEDS STUDENTS Have students explore the phrase "like dissolves like." Provide student pairs with pairs of liquids that are polar, pairs that are nonpolar, and pairs that contain one polar and one nonpolar liquid. Have students mix the two liquids in each pair and decide whether the liquids are like or unlike.

L3 ADVANCED STUDENTS Ask students to determine a method for proving if a bottled water product is pure water or if it is an aqueous solution. Have students present bottled water products with misleading labels.

Foundations for Reading

BUILD VOCABULARY Have students make a concept map using the following words: *solvation, solute, aqueous solution, solvent.*

READING STRATEGY For each section in this lesson, have students write a short summary identifying the main idea of the passage. Students can refer to these summaries when preparing for an assessment.

Explain

Solutions

START A CONVERSATION Remind students that an anion is any negatively charged atom or group of atoms. A cation is any positively charged atom or group of atoms. Have students suggest a memory aid or a symbol to help them remember these terms. *(Sample answer: The first two letters of* anion, a *and* n, *could represent "a negative", since anions are negative ions.)*

USE VISUALS Have students study Figure 15.8. Stress the idea that when a solid dissolves in water, it breaks into small pieces. **Ask** What must happen for an ionic solid to dissolve? *(The molecules of the solvent must be able to overcome the attractive forces acting between ions and holding the solid together.)* **Ask** What part of a water molecule is attracted to a negatively charged solute ion? *(the hydrogen atoms)*

Extend

Connect to PHYSIOLOGY

Remind students that solutions are homogeneous mixtures containing a solvent and one or more solutes. Explain that the solvent is typically defined as the component in the system that is present in the greatest amount. Point out that a water-soluble solute can be a solid, liquid, or gas. Have students identify some of the solutes found in blood. *(Solutes in blood are typically ions such as sodium, potassium, calcium, chloride, hydrogen carbonate, and phosphate. Glucose, a covalent compound, also is dissolved in blood. Dissolved gases such as oxygen and carbon dioxide are also present.)*

Answers

FIGURE 15.8 The positive hydrogen end of the water molecule orients itself toward the anion. The negative oxygen end of the water molecule orients itself toward the cation.

Extend

Electrolytes and Nonelectrolytes

START A CONVERSATION Display to the class the warning labels on some small electrical appliances, such as a hair dryer or an electric razor. **Ask** Why do these appliances warn you not to use them near water? *(because there are electrolytes in tap water)* **Ask** Why does tap water conduct electricity? *(Tap water comes from rivers, streams, and wells and contains dissolved ionic particles from rocks and river banks.)*

SUMMARIZE Have students summarize in a chart the types of compounds that strongly conduct an electrical current, weakly conduct an electrical current, and do not conduct an electrical current.

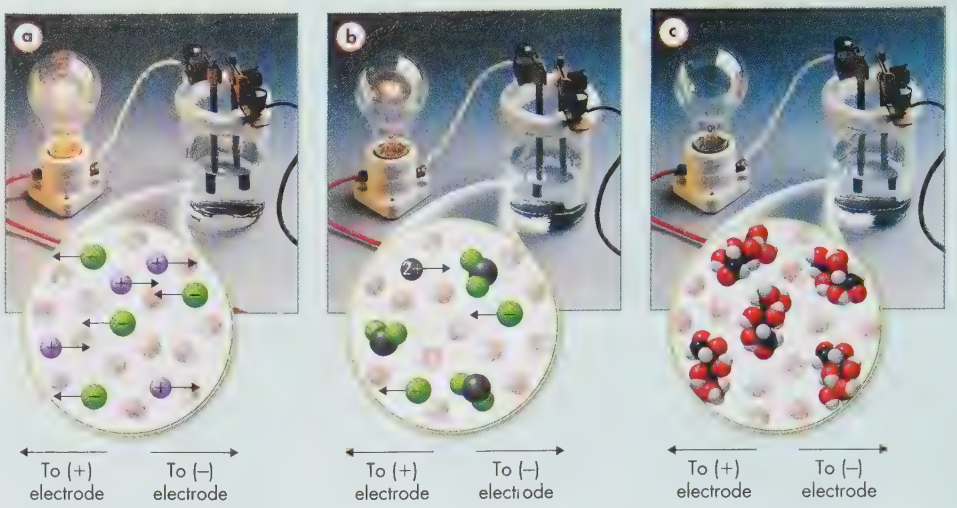

Figure 15.10 Conductivity of Solutions
A solution conducts an electric current if it contains ions. **a.** Sodium chloride, a strong electrolyte, is nearly 100 percent dissociated into ions in water. **b.** Mercury(II) chloride, a weak electrolyte, is only partially dissociated in water. **c.** Glucose, a nonelectrolyte, does not dissociate in water.
Predict ***Silver chloride dissolves only slightly in water. If the electrodes were immersed in a solution of silver chloride, would the bulb glow brightly, dimly, or not at all?***

Electrolytes and Nonelectrolytes

Why are all ionic compounds electrolytes?

Remember the glowing pickle? The pickle contained an electrolyte. An **electrolyte** is a compound that conducts an electric current when it is in an aqueous solution or in the molten state. Conduction of an electric current requires ions that are mobile and, thus, able to carry charges through a liquid.

All ionic compounds are electrolytes because they dissociate into ions. Sodium chloride, copper(II) sulfate, and sodium hydroxide are typical water-soluble electrolytes. Barium sulfate is an ionic compound that cannot conduct an electric current in aqueous solution because it is insoluble, but it can conduct in the molten state.

The experimental setup in Figure 15.10 can be used to determine whether a solution contains an electrolyte. In order for the bulb to light, an electric current must flow between the two electrodes that are immersed in the solution. If ions are present in the solution, they carry electrical charge from one electrode to the other, completing the electrical circuit.

A **nonelectrolyte** is a compound that does not conduct an electric current in either an aqueous solution or the molten state. Many molecular compounds are nonelectrolytes because they are not composed of ions. Most compounds of carbon, such as table sugar (sucrose) and the alcohol in rubbing alcohol (2-propanol), are nonelectrolytes.

UbD Check for Understanding

The Essential Question **How do aqueous solutions form?**

Assess students' understanding of the difference between how electrolyte and nonelectrolyte solutions form by asking students to give a thumbs up if they agree with the following statement: *Electrolyte solutions are characterized by charged ions separated by molecules of water. Nonelectrolyte solutions are characterized by uncharged molecules separated by water molecules.*

ADJUST INSTRUCTION If students have difficulty with this concept, review Figure 15.10 with students, and then ask them to evaluate the statement again.

Some polar molecular compounds are nonelectrolytes in the pure state but become electrolytes when they dissolve in water. This change occurs because such compounds ionize in solution. For example, neither ammonia ($NH_3(g)$) nor hydrogen chloride ($HCl(g)$) is an electrolyte in the pure state. Yet an aqueous solution of ammonia conducts an electric current because ammonium ions (NH_4^+) and hydroxide ions (OH^-) form when ammonia dissolves in water.

$$NH_3(g) + H_2O(l) \longrightarrow NH_4^+(aq) + OH^-(aq)$$

Similarly, in an aqueous solution, hydrogen chloride produces hydronium ions (H_3O^+) and chloride ions (Cl^-). An aqueous solution of hydrogen chloride conducts an electric current and is therefore an electrolyte.

$$HCl(g) + H_2O(l) \longrightarrow H_3O^+(aq) + Cl^-(aq)$$

Not all electrolytes conduct an electric current to the same degree. In Figure 15.10, the bulb glows brightly when the electrodes are immersed in a sodium chloride solution. The bright glow shows that sodium chloride is a strong electrolyte because nearly all the dissolved sodium chloride exists as separate Na^+ and Cl^- ions. In a solution that contains a **strong electrolyte,** all or nearly all of the solute exists as ions. The ions move in solution and conduct an electric current. Most soluble salts, inorganic acids, and inorganic bases are strong electrolytes.

The bulb glows dimly when the electrodes are immersed in a mercury(II) chloride solution because mercury(II) chloride is a weak electrolyte. A **weak electrolyte** conducts an electric current poorly because only a fraction of the solute in the solution exists as ions. Organic acids and bases are also examples of weak electrolytes. In a solution of glucose, the bulb does not glow. Glucose ($C_6H_{12}O_6$) is a molecular compound. It does not form ions, so it is a nonelectrolyte.

Electrolytes are essential to all metabolic processes. Your cells use electrolytes, such as sodium and potassium ions, to carry electrical impulses internally and to other cells. These impulses are crucial to nerve and muscle function. The kidneys help to maintain balanced electrolyte concentrations in the blood. However, an electrolyte imbalance can occur if you become dehydrated. For example, when you exercise, you can lose water and electrolytes from your body through perspiration. The athlete in Figure 15.11 understands that it is important to replenish these electrolytes by eating salty foods or by drinking sports drinks.

CHEMISTRY & YOU

Q: *Pickles contain table salt. Why can electric current flow through a pickle, causing it to glow?*

Figure 15.11 Sports Drinks It is important to replenish electrolytes when exercising or sweating. Sports drinks often contain sodium and potassium.

Professional Development Note

Metabolic Process

Electrolytes are essential to all metabolic processes. Sodium and potassium ions control nerve impulse transmission and muscle contraction. If renal function is impaired or malabsorption from the gut disturbs optimum sodium and potassium levels, then serious nervous-system problems arise. Loss of consciousness or difficulty in maintaining muscle coordination could result. Any condition that causes prolonged bouts of diarrhea can be life threatening because of the dramatic loss of electrolytes. Electrolytes are excreted through the skin via sweat, and they must be replenished or cramps and heat stroke may occur. Sports drinks are a good source of electrolytes; they contain Na^+, K^+, and Ca^{2+}.

CHEMISTRY & YOU Table salt, or sodium chloride, is a strong electrolyte.

Explore

Class Activity

PURPOSE Students will compare electrolytes by using a conductivity tester.

MATERIALS light bulb in a porcelain socket; 9V or lantern battery; 2 copper metal strips; lamp cord; alligator clips; 0.1*M* solutions of glucose ($C_6H_{12}O_6$), alanine ($HC_3H_6O_2N$), glycine ($HC_2H_4O_2N$), ascorbic acid ($HC_6H_7O_6$), malonic acid ($H_2C_3H_2O_4$), citric acid ($H_3C_6H_5O_7$), acetic acid ($HC_2H_3O_2$), and hydrochloric acid (HCl); 8 beakers labeled 1–8; marking pen

The complete circuit consists of a light bulb (in a porcelain socket), a 9V or lantern battery, and two copper metal strips to be immersed in the test solution. Make connections to the battery and light bulb socket by using the lamp cord and alligator clips. If possible, prepare eight such testers so that students can directly compare the brightnesses of the light bulbs.

PROCEDURE Write the names and numbers of the beakers on the board. Pour an equal volume of a different solution into each labeled beaker. Remind students that all the solutions have the same concentration (0.1*M*). Immerse a pair of electrodes in each solution and have students compare the brightnesses of the light bulb. Direct students to list the substances in order from strongest to weakest electrolytes. Remind students that a strong electrolyte is a substance that exists in solution almost entirely as ions. A weak electrolyte is a substance that only partly dissociates into ions in solution.

EXPECTED OUTCOME Students infer that the different substances are dissociated, or ionized, to different extents.

Answers

FIGURE 15.10 The bulb will glow dimly.

Explain

Hydrates

USE VISUALS Have students examine Figure 15.12. **Ask** What is a hydrate? *(a compound that contains weakly bound water molecules as part of its crystal structure)* **Ask** What does the solid dot between the $CuSO_4$ and the $5H_2O$ in the compound formula mean? *(It indicates that water is an integral part of the representative unit of the compound.)* **Ask** How can the presence of water in the structure of the crystal lattice be inferred? *(by the change in the appearance of the hydrated substance when the water is driven off)*

Explore

Teacher Demo

PURPOSE Students will observe the color change when a hydrate gains and loses water.

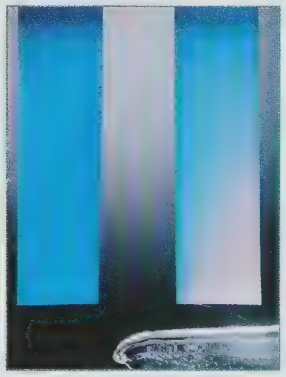
MATERIALS $CoCl_2 \cdot 6H_2O$ solution, cotton swab, white paper, hot plate, misting bottle, water.

PROCEDURE Use a cotton swab to draw a picture or write a message on a piece of white paper by using a solution of hydrated cobalt(II) chloride. Place the paper on a warm (not hot) hot plate until the writing dries. Use a misting bottle to mist water onto the paper. The paper can also be used to indicate the presence of humidity in the air.

SAFETY AND DISPOSAL Wear gloves. Cobalt chloride is toxic if ingested. Collect the cobalt chloride solution, evaporate it to dryness, place the cooled residue in a bag, and label the bag for disposal.

EXPECTED OUTCOMES The picture or message will appear blue when the paper dries and pink when the paper is misted with water.

Figure 15.12 Heating a Hydrate
Water can be driven from a hydrate by heating it. **a.** Heating of a sample of blue $CuSO_4 \cdot 5H_2O$ begins. **b.** After a time, much of the blue hydrate has been converted to white anhydrous $CuSO_4$.



Hydrates

Why do hydrates easily lose and regain water?

When an aqueous solution of copper(II) sulfate is allowed to evaporate, deep-blue crystals of copper(II) sulfate pentahydrate are deposited. The chemical formula for this compound is $CuSO_4 \cdot 5H_2O$. Water molecules are an integral part of the crystal structure of copper(II) sulfate pentahydrate and many other substances. The water contained in a crystal is called the **water of hydration** or water of crystallization. A compound that contains water of hydration is called a **hydrate.** In writing the formula of a hydrate, use a dot to connect the formula of the compound and the number of water molecules per formula unit. Crystals of copper(II) sulfate pentahydrate always contain five molecules of water for each copper and sulfate ion pair. The deep-blue crystals are dry to the touch. They are unchanged in composition or appearance in normally moist air. However, when the crystals are heated above 100°C, they lose their water of hydration. **The forces holding the water molecules in hydrates are not very strong, so the water is easily lost and regained.** Figure 15.12 shows how the blue crystals of $CuSO_4 \cdot 5H_2O$ crumble to a white anhydrous powder that has the formula $CuSO_4$. A substance that is **anhydrous** does not contain water. If anhydrous copper(II) sulfate is treated with water, the blue pentahydrate is regenerated.

$$CuSO_4 \cdot 5H_2O(s) \underset{\text{heat}}{\overset{+\text{heat}}{\rightleftharpoons}} CuSO_4(s) + 5H_2O(g)$$

Figure 15.13 Exposing a Hydrate to Moist Air
Paper dipped in an aqueous cobalt(II) chloride solution and then dried is blue. In the presence of moisture, the paper turns pink.
Infer ***How could you change the pink paper back to blue?***

Another compound that changes color in the presence of moisture is cobalt(II) chloride. A piece of filter paper that has been dipped in an aqueous solution of cobalt(II) chloride and then dried is blue in color (anhydrous $CoCl_2$). As you can see in Figure 15.13, when the paper is exposed to moist air, it turns pink because of the formation of the hydrate cobalt(II) chloride hexahydrate ($CoCl_2 \cdot 6H_2O$). The blue paper could be used to test for the presence of water.

Some familiar hydrates are listed in Table 15.2. Each one contains a fixed quantity of water and has a definite composition. To determine what percent by mass of a hydrate is water, first determine the mass of water in one mole of hydrate. Then determine the molar mass of the hydrate. The percent by mass of water can be calculated using the following equation:

$$\text{Percent by mass } H_2O = \frac{\text{mass of water}}{\text{mass of hydrate}} \times 100\%$$

UbD

Check for Understanding

Why are all ionic compounds electrolytes?

Assess students' knowledge about electrolytes by asking them to signal true or false to the following statements. Have students signal true with a thumbs up and false with a thumbs down.

- All solutions are conductors of electricity. *(false)*
- Degree of electrical conductivity is directly related to kinetic energy. *(false)*
- Ionic compounds conduct electricity because they contain ions. *(true)*
- Molecular compounds conduct electricity because they do not contain ions. *(false)*

ADJUST INSTRUCTION If students are having difficulty answering, direct them to reexamine Figure 15.10 and reread the text that follows. Then ask them to respond to the statements again.

Table 15.2

Some Common Hydrates

Formula	Chemical name	Common name
$MgSO_4 \cdot 7H_2O$	Magnesium sulfate heptahydrate	Epsom salt
$Ba(OH)_2 \cdot 8H_2O$	Barium hydroxide octahydrate	
$CaCl_2 \cdot 2H_2O$	Calcium chloride dihydrate	
$CuSO_4 \cdot 5H_2O$	Copper(II) sulfate pentahydrate	Blue vitriol
$Na_2SO_4 \cdot 10H_2O$	Sodium sulfate decahydrate	Glauber's salt
$KAl(SO_4)_2 \cdot 12H_2O$	Potassium aluminum sulfate dodecahydrate	Alum
$Na_2B_4O_7 \cdot 10H_2O$	Sodium tetraborate decahydrate	Borax
$FeSO_4 \cdot 7H_2O$	Iron(II) sulfate heptahydrate	Green vitriol
$H_2SO_4 \cdot H_2O$	Sulfuric acid hydrate (mp 8.6°C)	

Efflorescent Hydrates The water molecules in hydrates are held by weak forces, so hydrates often have an appreciable vapor pressure. If a hydrate has a vapor pressure higher than the pressure of water vapor in the air, the hydrate will lose its water of hydration or **effloresce.** For example, copper(II) sulfate pentahydrate has a vapor pressure of about 1.0 kPa at room temperature. The average pressure of water vapor at room temperature is about 1.3 kPa. Copper(II) sulfate pentahydrate is stable until the humidity decreases. When the vapor pressure drops below 1.0 kPa, the hydrate effloresces. Washing soda, or sodium carbonate decahydrate ($Na_2CO_3 \cdot 10H_2O$), is efflorescent. As the crystals lose water of hydration, they effloresce and become coated with a white powder of anhydrous sodium carbonate (Na_2CO_3).

Hygroscopic Hydrates Hydrated ionic compounds that have a low vapor pressure remove water from moist air to form higher hydrates. These hydrates and other compounds that remove moisture from air are called **hygroscopic.** For example, calcium chloride monohydrate spontaneously absorbs a second molecule of water when exposed to moist air.

$$CaCl_2 \cdot H_2O(s) \xrightarrow{\text{moist air}} CaCl_2 \cdot 2H_2O(s)$$

Calcium chloride is used as a desiccant in the laboratory. A **desiccant** is a substance used to absorb moisture from the air and create a dry atmosphere. Anhydrous calcium chloride can be placed in the bottom of a tightly sealed container called a desiccator, which is shown in Figure 15.14. Substances that must be kept dry are stored inside. A solid desiccant such as calcium sulfate ($CaSO_4$) can also be added to a liquid solvent, such as ethanol, to keep it dry. The calcium sulfate does not dissolve appreciably in the solvent but absorbs water from the ethanol. When a desiccant has absorbed all the water it can hold, the compound can be returned to its anhydrous state by heating.

Figure 15.14 Desiccator
A desiccator may contain calcium chloride. Substances that must be kept dry are stored inside.

START A CONVERSATION Many of the terms used to describe the properties of hydrates may be unfamiliar to students. Review the definitions and pronunciations of the terms *effloresce, hygroscopic, desiccant,* and *deliquescent.* Have students write the definition for each term in their vocabulary notebooks.

Demonstrate some of these properties of hydrates by setting out watch glasses containing fresh sodium hydroxide pellets, anhydrous calcium chloride, and anhydrous copper sulfate. Advise students not to touch the compounds. Point out the compounds that are hygroscopic and those that are deliquescent. Many students may have seen rice in salt shakers at restaurants or at home. **Ask** What purpose does the rice serve? (*Rice acts as a desiccant.*) Explain why hygroscopic agents are preferred over deliquescent agents for use as desiccants, or drying agents. Emphasize the reversible properties of hydration. Point out that desiccants can be recycled by heating to drive off absorbed water. If possible, show students a desiccator, and explain why desiccators are used in the laboratory to store hygroscopic chemicals.

USE VISUALS Display Table 15.2 on an overhead projector. Review the nomenclature used to name salts and the use of prefixes to indicate the number of water molecules in the crystalline hydrate. **Ask** Do you know some of the familiar uses for the compounds in the table? *(Epsom salt is used as a laxative; Glauber's salt is used as a laxative or diuretic; alum is used as an astringent, as an emetic, and in the manufacture of baking powder, dyes, and paper; borax is used in the manufacture of glass, enamel, artificial gems, soaps, and antiseptics.)*

Desiccants

Cameras and electronic equipment made in Japan and other Asian countries are usually shipped to the United States in the holds of ships. Because ocean air contains so much moisture, the packaging for this equipment usually contains small packets of a desiccant. The desiccant absorbs the water vapor from the air, preventing it from condensing on the delicate wiring and circuit boards of the equipment, possibly causing corrosion and short circuits.

Answers

FIGURE 15.13 Heat it gently to drive off the water.

Explain

Sample Practice Problem

Determine the percent by mass of water in calcium chloride dihydrate to the nearest tenth: $CaCl_2 \cdot 2H_2O$. *(24.5%)*

Extend

After students have studied Sample Problem 15.1, have them work in groups to find the percent by mass of water in the compounds listed in Table 15.2.

($MgSO_4 \cdot 7H_2O$, 51.1%; $Ba(OH)_2 \cdot 8H_2O$, 45.7%; $CaCl_2 \cdot 2H_2O$, 24.5%; $CuSO_4 \cdot 5H_2O$, 36.1%; $Na_2SO_4 \cdot 10H_2O$, 55.9%; $KAl(SO_4)_2 \cdot 12H_2O$, 45.5%; $Na_2B_4O_7 \cdot 10H_2O$, 47.2%; $FeSO_4 \cdot 7H_2O$, 45.3%; $H_2SO_4 \cdot H_2O$, 15.5%)

Sample Problem 15.1

Finding the Percent by Mass of Water in a Hydrate

Calculate the percent by mass of water in washing soda, sodium carbonate decahydrate ($Na_2CO_3 \cdot 10H_2O$).

1 Analyze **List the known and the unknown.** To determine the percent by mass, divide the mass of water in the one mole of the hydrate by the molar mass of the hydrate and multiply by 100%.

KNOWN

formula of hydrate = $Na_2CO_3 \cdot 10H_2O$

UNKNOWN

percent H_2O = ?%

2 Calculate **Solve for the unknown.**

For every 1 mol of $Na_2CO_3 \cdot 10H_2O$, there are 10 mol of H_2O.

Determine the mass of 10 mol of water.

mass of 10 mol H_2O = 10 [(2 × 1.0 g) + 16.0 g] = 180.0 g

Determine the mass of 1 mol of the hydrated compound.

molar mass of $Na_2CO_3 \cdot 10H_2O$ = (2 × 23.0 g) + 12.0 g + (3 × 16.0 g) + 180.0 g = 286.0 g

Calculate the percent by mass of water in the hydrate.

$$\text{percent by mass } H_2O = \frac{\text{mass of water}}{\text{mass of hydrate}} \times 100\%$$

$$= \frac{180.0\ g}{286.0\ g} \times 100\% = 62.94\%$$

3 Evaluate **Does the result make sense?** The mass of the water accounts for more than half the molar mass of the compound, so a percentage greater than 50 percent is expected.

8. What is the percent by mass of water in $CuSO_4 \cdot 5H_2O$?

In Problem 8, start by determining the mass of 5 mol of water and 1 mol of the hydrate.

9. If you need 5.00 g of anhydrous Na_2CO_3 for your reaction, how many grams of $Na_2CO_3 \cdot 10H_2O$ could you use instead?

You know from the Sample Problem above that 62.94% of the hydrate is water, so 37.06 g out of every 100 g of the hydrate is Na_2CO_3.

Foundations for Math

ORDER OF OPERATIONS AND THE CALCULATOR Point out that finding the percent by mass of water in hydrates involves several uses of the order of operations. Students must use the correct order of operations each time they find the molar mass. If students use a calculator, encourage them to use grouping symbols when they enter the values in the calculator.

In **Sample Problem 15.1,** students should enter the calculation for the molar mass of Na_2CO_3 as (2 × 23) + 12 + (3 × 16) to ensure that the calculator follows the correct order of operations.

Deliquescent Compounds Have you ever noticed the small packets of silica gel that are often packaged with electronic equipment and leather goods? Although the structure of silica gel is not the same as a hydrated salt, it is a hygroscopic substance used to absorb moisture from the surrounding air to prevent damage to sensitive equipment and materials. Some compounds are so hygroscopic that they become wet when exposed to normally moist air. These compounds are **deliquescent,** which means that they remove sufficient water from the air to dissolve completely and form solutions. Figure 15.15 shows that pellets of sodium hydroxide are deliquescent. For this reason, containers of sodium hydroxide and other deliquescent chemicals should always be tightly stoppered and the chemicals should never come in contact with your skin. The solution formed by a deliquescent substance has a lower vapor pressure than that of the water in the air.

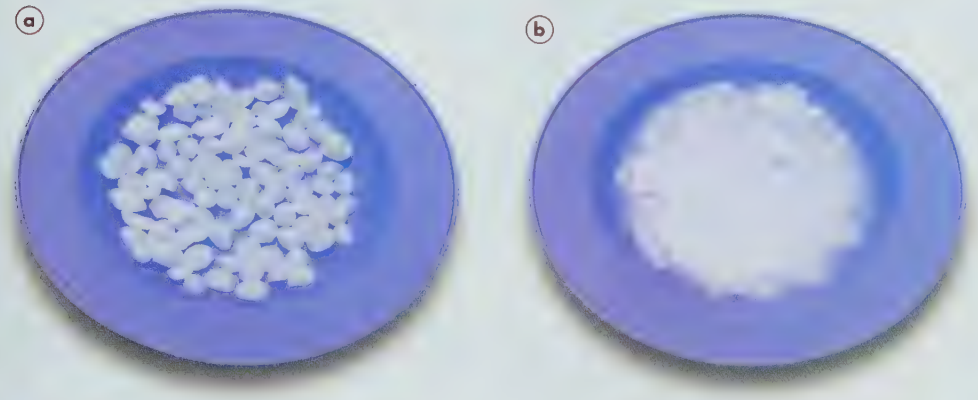


Figure 15.15 Sodium Hydroxide Deliquescent substances, such as sodium hydroxide, can remove water from the air. **a.** Sodium hydroxide pellets absorb moisture from the air. **b.** Eventually a solution is formed. **Classify** *What is the solvent? What is the solute?*

15.2 LessonCheck

10. Identify What types of substances dissolve most readily in water?

11. Review What property of all ionic compounds make them electrolytes?

12. Explain Why do hydrates easily lose water when heated and regain water when exposed to moisture?

13. Classify Identify the solvent and the solute in vinegar, a dilute aqueous solution of acetic acid.

14. Calculate What is the percent by mass of water in iron(II) sulfate heptahydrate ($FeSO_4 \cdot 7H_2O$)?

15. Compare Is the percent by mass of copper in $CuSO_4 \cdot 5H_2O$ the same as in $CuSO_4$? Explain.

16. Compare and Contrast Distinguish between efflorescent and hygroscopic substances.

BIG IDEA BONDING AND INTERACTIONS

17. Which of the following substances dissolve to a significant extent in water? Explain your answer in terms of the interactions between the solvent and solute.

a. CH_4
b. KCl
c. He
d. $MgSO_4$
e. Sucrose ($C_{12}H_{22}O_{11}$)
f. $NaHCO_3$

Lesson Check Answers

10. Ionic compounds and polar covalent compounds

11. They dissociate into ions.

12. The forces holding the water molecules in hydrates are not very strong, so the water is easily lost and regained.

13. The solute is acetic acid. The solvent is water.

14. 46%

15. The percents of copper in copper sulfate and copper sulfate pentahydrate are different because the formula masses of the two compounds are different.

16. Efflorescent compounds such as certain hydrates lose water to the air. Hygroscopic compounds remove moisture from air, sometimes forming hydrates.

17. a. insoluble, nonpolar
b. soluble, ionic
c. insoluble, nonpolar
d. soluble, ionic
e. soluble, polar
f. soluble, ionic

Evaluate

Informal Assessment

To assess students' understanding of the properties of aqueous solutions, show students the following activity and ask them to answer each question.

Dissolve a small amount of nickel(II) chloride in 500 mL of distilled water.

1. What is the solute and what is the solvent? *(Water is the solvent and nickel(II) chloride is the solute.)*
2. What type of electrolyte is nickel(II) chloride? How do you know? *(Nickel(II) chloride is an ionic compound and is soluble in water; therefore, it is a strong electrolyte.)*
3. What types of substances will dissolve in water to form aqueous solutions? *(ionic compounds and polar covalent molecules)*

Then have students complete the 15.2 Lesson Check.

Reteach

Project models of water molecules, cations, and anions on an overhead projector to show how water molecules orient their dipoles to solvate ions. Point out that cations and anions are attracted to different ends of the water molecule. Stress that the classification of water-soluble substances as strong electrolytes, weak electrolytes, or nonelectrolytes is determined by the relative number of ions in solution. Explain that nonelectrolytes do not produce ions.

Answers

8. 36.1%

9. 13.5 g $Na_2CO_3 \cdot 10H_2$

FIGURE 15.15 The solvent is water and the solute is sodium hydroxide.

CHEMISTRY & YOU Students should be familiar with the process of osmosis in biological systems and understand that water flows across a membrane *toward* an area of high concentration. In contrast, reverse osmosis requires water to flow *away* from an area of high concentration. Just as in a biological system, the process of moving water away from a highly concentrated solution toward a more dilute one requires an input of energy. In this case, a high-pressure differential is used to force the water through a semi-permeable membrane. It is this requirement of high pressure that creates a problem for reverse osmosis: the higher the efficiency of the process, the higher the pressure provided must be, thus increasing the energy costs.

Pose the following question to students: *Considering both its benefits and problems, why is reverse osmosis a highly desirable solution for water filtration?* You may need to assist students in the following ways:

- Reverse osmosis can be used to filter any water, not just saltwater.
- A reasonably high efficiency of reverse osmosis can be achieved only in large filtration plants, which can provide the high pressure needed.
- Reverse osmosis can be performed on a small scale, even in faucet and aquarium filters.
- Membranes used for reverse osmosis must be frequently replaced.

21st Century Learning To be successful in the 21st century, students need skills and learning experiences that extend beyond subject matter mastery. The following project helps students build the following 21st Century Skills: *Financial, Economic, Business, and Entrepreneurial Literacy; Creativity and Innovation; Critical Thinking and Problem Solving; Communication and Collaboration; Information Literacy;* and *Initiative and Self-Direction.*

Pose the following challenge to students: *A local coastal government is trying to decide between distillation and reverse osmosis for a city's new water filtration plant. Form a team of 3–5 students to represent a local citizens' group that favors reverse osmosis over distillation, and prepare an advocacy report supporting your views on this technology.* Presentations should be prepared and submitted electronically and should include a suggested site for the plant. Students should include information on the pros and cons of the technology, its potential environmental impact, and its economic feasibility.

Pros & Cons

Advantages of Reverse Osmosis Desalination	Disadvantages of Reverse Osmosis Desalination
✔ **Expands drinking water resources** Some areas of the world do not have abundant sources of drinking water. Reverse osmosis desalination provides drinking water in cases of drought, water shortages, or national disasters.	✘ **High energy consumption** The cost of running a reverse osmosis desalination plant is high compared to other methods for obtaining drinking water.
✔ **Low environmental impact** The conversion of saltwater to drinking water via reverse osmosis desalination uses minimal chemicals.	✘ **Low efficiency** The volume of drinking water produced is low compared to the volume of seawater treated.
✔ **Low start-up costs** The cost to install a reverse osmosis desalination facility is relatively low.	✘ **Potentially harmful to sea life** The process of removing seawater and returning brine to the ocean can disturb marine environments.

Take It Further

1. Classify Would you consider seawater to be a homogeneous aqueous system or a heterogeneous aqueous system? Explain.

2. Infer Brine is more dense than seawater. How might the release of brine back into the ocean affect the marine environment?

Differentiated Instruction

L1 STRUGGLING STUDENTS Have students work in small groups to produce a poster demonstrating the process by which a desalination plant filters saltwater. Posters should include the saltwater intake, flow through the semi-permeable membrane, and water and brine outflow.

LPR LESS PROFICIENT READERS Help students understand the term *desalination* by explaining the connection between the term *saline* and saltwater. Point out that *desalination* can be referred to as the process of "de-salting" water.

L3 ADVANCED STUDENTS Divide students into pairs. Have the pairs research how desalination has evolved over the years and what advantages reverse osmosis desalination has over earlier methods. Have students present their findings to the class. Encourage creativity in the presentation medium.

Explain

MAKE A CONNECTION One of the key difficulties in setting up reverse osmosis facilities is the high pressure required to efficiently process saltwater. Remind students that the principle of osmosis is ultimately the reason for the requirement of a high-pressure differential. In a situation where the solute concentrations are drastically different on the two sides of a membrane, there is naturally a relatively high pressure exerted toward the higher concentration. This causes difficulty during the process of reverse osmosis because not only must the water be forced through the membrane but the system must also overcome the natural pressure of osmosis.

Extend

Connect to ENVIRONMENTAL SCIENCE

The principal environmental concern from reverse osmosis desalination is the fact that an inevitable byproduct of the process is a concentrated mix of salts and impurities known as brine. The brine has a much higher salinity than ocean water and is therefore poisonous to marine wildlife. It is especially harmful to bottom-dwelling animals because brine sinks due to its higher solute concentration. Have students brainstorm potential ways in which the environmental impact due to the release of brine could be minimized.

Answers

1. Seawater is a homogeneous aqueous system because it is an aqueous solution.
2. Since brine is more dense than seawater, it will sink to the bottom of the ocean. The brine could affect marine life that live on the ocean floor.

LESSON 15.3

Key Objectives

15.3.1 DISTINGUISH between a suspension and a solution.

15.3.2 IDENTIFY how to distinguish a colloid from a suspension and a solution.

Additional Resources

- Reading and Study Workbook, Lesson 15.3
- Core Teaching Resources, Lesson 15.3 Review
- Small-Scale Chemistry Laboratory Manual, Lab 24

PearsonChem.com

Engage

CHEMISTRY & YOU Have students study the photograph and read the text. Comment that the atmosphere is referred to as a homogeneous mixture called a colloid. **Ask** What does that tell you about the composition of the atmosphere? *(Its composition is not uniform throughout.)* **Ask** If a colloid such as the atmosphere differs from a solution with respect to the size of its particles, would you expect a colloid to have smaller or larger particles than a solution? *(larger)*

Activate Prior Knowledge

Review solutions and the solution process. Ask students to explain why the particles in a homogeneous aqueous system can pass through a filter, and have them predict whether the same can happen when filtering heterogeneous systems.

Foundations for Reading

BUILD VOCABULARY Have students make a Venn diagram using the following vocabulary terms: *solution, suspension, colloid, Tyndall effect, Brownian motion.*

IN ACADEMIC STANDARDS for SCIENCE

C.7.1 Describe the composition and properties of types of solutions.

15.3 Heterogeneous Aqueous Systems

C.7.1 Composition and properties of solutions

CHEMISTRY & YOU

Q: *Why are some sunsets red?* Have you ever wondered what causes the red glow of the evening sky? The atmosphere contains particles of water and dust. As sunlight passes through the particles, it is scattered. However, not all wavelengths are scattered to the same extent. The shorter wavelengths of visible light (blue and green) are scattered more than the longer wavelengths (red and orange). At sunrise and sunset, the longer wavelengths are more visible because the sun's light travels through more of Earth's atmosphere.

Key Questions

What is the difference between a suspension and a solution?

What distinguishes a colloid from a suspension and a solution?

Vocabulary

- suspension
- colloid
- Tyndall effect
- Brownian motion
- emulsion

Suspensions

What is the difference between a suspension and a solution?

So far in this chapter, you have learned about aqueous solutions, which are homogeneous mixtures. In contrast, heterogeneous mixtures are not solutions. If you shake a container containing a piece of clay with water, the clay breaks into fine particles. The water becomes cloudy because the clay particles are suspended in the water. If you stop shaking, the particles settle out. A **suspension** is a mixture from which particles settle out upon standing. **A suspension differs from a solution because the particles of a suspension are much larger and do not stay suspended indefinitely.** The particles in a typical suspension have an average diameter greater than 1000 nm. By contrast, the particle size in a solution is usually about 1 nm.

Suspensions are heterogeneous because at least two substances can be clearly identified. In the example of clay particles mixed with water, you can clearly see the dispersed phase (clay) in the dispersion medium (water). Figure 15.16 shows how the difference between a solution and suspension is easily seen when each type of mixture is filtered.

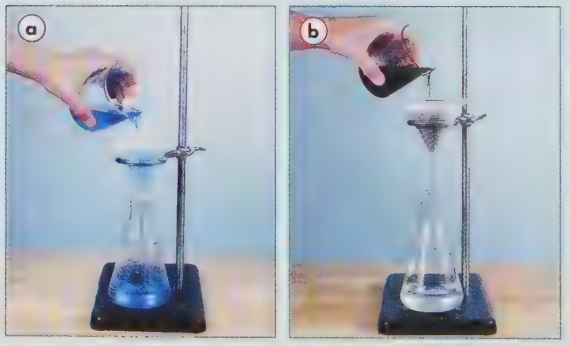

Figure 15.16
Solutions and Suspensions
A solution is a homogeneous mixture. A suspension is a heterogeneous mixture. **a.** The small size of the solute particles in a solution allows them to pass through filter paper. **b.** The suspended particles of a suspension can be removed by filtration.

Focus on ELL

1 CONTENT AND LANGUAGE Have students use a dictionary to look up the various uses of the word *disperse* or *dispersion*. Ask students to explain how the seeds of a plant being dispersed by the wind are related to the dispersed phase and dispersion medium of a colloid.

2 FRONTLOAD THE LESSON Provide students with a partially completed compare-contrast table for heterogeneous solutions, and ask them to complete the table as they read the lesson. Students should then use the self-questioning strategy to note the similarities and differences between the solutions.

3 COMPREHENSIBLE INPUT Provide small groups of students samples of saltwater, oil-and-vinegar salad dressing, mayonnaise, and grape jelly to compare macroscopically and microscopically. Assign students the online Concepts in Action activity on emulsions.

Colloids

What distinguishes a colloid from a suspension and a solution?

Gelatin is an example of a type of mixture called a colloid. A **colloid** is a heterogeneous mixture containing particles that range in size from 1 nm to 1000 nm. The particles are spread, or dispersed, throughout the dispersion medium, which can be a solid, liquid, or a gas. The first substances to be identified as colloids were glues. Other colloids include such mixtures as paint, aerosol sprays, and smoke. Table 15.3 lists some common colloidal systems and gives examples of familiar colloids.

How do the properties of colloids differ from those of suspensions and solutions? Many colloids are cloudy or milky in appearance, like suspensions, when they are concentrated. Colloids may look clear or almost clear, like solutions, when they are dilute. The important difference between colloids and solutions and suspensions is in the size of the particles. **Colloids have particles smaller than those in suspensions and larger than those in solutions.** These intermediate-sized particles cannot be retained by filter paper as are the larger particles of a suspension, and they do not settle out with time. Colloids can be distinguished by a phenomenon called the Tyndall effect and by the observation of Brownian motion. They are also subject to coagulation or clumping together, and they can be emulsified or made stable.

Table 15.3

Some Colloidal Systems

System			
Dispersed phase	Dispersion medium	Type	Example
Gas	Liquid	Foam	Whipped cream
Gas	Solid	Foam	Marshmallow
Liquid	Liquid	Emulsion	Milk, mayonnaise
Liquid	Gas	Aerosol	Fog, aerosol
Solid	Gas	Smoke	Dust in air
Solid	Liquid	Sols, gels	Egg white, jelly, paint, blood, starch in water, gelatin

UbD Understanding by Design

What is the difference between a suspension and a solution?

Assess students' knowledge about heterogeneous aqueous systems by asking them to explain how to tell if a sample of an aqueous system is homogeneous or heterogeneous.

ADJUST INSTRUCTION If students are having difficulty distinguishing between the two systems, have them review the Solutions section in Lesson 15.2 and the Suspensions section in Lesson 15.3. Then have students revise their answers.

READING STRATEGY Before students begin to read this lesson, have them preview the pages and predict how the properties of suspensions and colloids differ from those of solutions. Then, as they read, have them correct any misconceptions they may have.

Explain

Suspensions

APPLY CONCEPTS Explain to students that municipal wastewater treatment plants take advantage of the properties of suspensions during the water treatment process. Point out that sewage is a suspension rather than a solution. This allows treatment facilities to use sedimentation to remove larger particles. Then, lime and alum are added to help coagulate smaller particles before the remaining liquid is filtered through sandy loams (diatomaceous earth). This process removes the remaining suspended particles. The diatomaceous earth may also absorb colloidal material.

Colloids

USE VISUALS Display Table 15.3 on an overhead projector. Explain that colloids are characterized by the physical state of the *dispersed phase* and of the *continuous phase*—also called the *dispersion medium*. **Ask** What is the dispersion medium in fog? *(air)* **Ask** What is dispersed in fog? *(water droplets)* Help students understand this two-part system by comparing it to a solution, which, instead of a dispersed phase and a dispersion medium, consists of a solute and a solvent.

Extend

Explain that homogenized milk is a colloid of protein and fat. Curdling occurs when bacteria produce enough lactic acid to cause dispersed protein and fat particles to coagulate into larger particles, which then separate from the rest of the mixture. Have students write an analogy to explain how this process is comparable to the clotting of blood.

Explain

START A CONVERSATION Point out that the main difference between solutions, suspensions, and colloids is particle size. Solution particles are typically less than 1 nm in diameter. Colloid particle are between 1 nm and 1000 nm in diameter. Suspension particles are typically larger than 1000 nm. Smaller particles are less susceptible to the effects of gravity and are influenced more by the effects of Brownian motion. The collisions of molecules with extremely small colloidal particles are sufficiently energetic to move colloidal particles in a random fashion that prevents their settling to the bottom.

Explore

The Tyndall Effect

Teacher Demo

PURPOSE Students will observe the Tyndall effect.

MATERIALS whole milk, water, beaker, stirring rod, projector or laser pointer

PROCEDURE Add a small amount of whole milk to some water in a beaker, and stir to mix. In a darkened room, shine a light from a projector or a laser pointer through the beaker.

SAFETY If a laser pointer is used, warn students not to look directly at it.

EXPECTED OUTCOME When viewed from the side, the path of the light beam is observed. This is the Tyndall effect. Students also can observe Brownian motion of airborne dust particles in the light beam.

CHEMISTRY & YOU You will have a better chance of seeing a red sunset if the air contains a lot of water and dust particles. That way more of the shorter wavelengths of light will be scattered from the sunlight leaving the the sky with a reddish appearance.

Figure 15.17 Scattering of Light The path of light is visible only when the light is scattered by particles. **a.** Fog or mist is a colloid and thus exhibits the Tyndall effect. **b.** Solutions do not scatter light. Particles in colloids and suspensions reflect or scatter light in all directions.
Explain *Why is it easier to see the light beam of an automobile on a foggy night than on a clear night?*

The Tyndall Effect Ordinarily you cannot see a beam of sunlight unless the light passes through particles of water (mist) or dust in the air. These particles scatter the sunlight. Similarly, a beam of light is visible as it passes through a colloid. The scattering of visible light by colloidal particles is called the **Tyndall effect.** Suspensions also exhibit the Tyndall effect. Solutions do not exhibit the Tyndall effect. The particles in solutions are too small to scatter light. Figure 15.17 shows how the Tyndall effect can differentiate solutions from colloids and suspensions.

Brownian Motion Flashes of light, or scintillations, are seen when colloids are studied under a microscope. Colloids scintillate because the particles reflecting and scattering the light move erratically. The chaotic movement of colloidal particles, which was first observed by the Scottish botanist Robert Brown (1773–1858), is called **Brownian motion.** Brownian motion is caused by collisions of the molecules of the dispersion medium with the small, dispersed colloidal particles. These collisions help prevent the colloidal particles from settling.

CHEMISTRY & YOU

Q: *What would be the ideal conditions to see a red sunset?*

Coagulation Colloidal particles also tend to stay suspended because they become charged by adsorbing ions from the dispersing medium onto their surface. *Adsorption* means to adhere to a surface. Some colloidal particles become positively charged by adsorbing positively charged ions. Other colloidal particles become negatively charged by adsorbing negatively charged ions. All the colloidal particles in a particular colloidal system will have the same charge, although the colloidal system is neutral. The repulsion between the like-charged particles prevents the particles from forming heavier aggregates that would have a greater tendency to settle out. Thus, a colloidal system can be destroyed or coagulated by the addition of electrolytes. The added ions neutralize the charged colloidal particles. The particles can clump together to form heavier aggregates and settle out from the dispersion.

Professional Development Note

Paint

Students may be interested in knowing why paint must be stirred before it is used. Explain that latex paint is a complex mixture of binders, pigments, and drying agents. Some ingredients are water soluble; others are present as dispersed particles. For uniform color and composition, the paint must be stirred well before being used.

Emulsions Mayonnaise is an example of a colloidal system called an emulsion. An **emulsion** is a colloidal dispersion of a liquid in a liquid. An emulsifying agent is essential for the formation of an emulsion and for maintaining the emulsion's stability. For example, oils and greases are not soluble in water. However, oils and greases readily form a colloidal dispersion if soap or detergent is added to the water. Soaps and detergents are emulsifying agents. One end of a large soap or detergent molecule is polar and is attracted to water molecules. The other end of the soap or detergent molecule is nonpolar and is soluble in oil or grease. Soaps and other emulsifying agents thus allow the formation of colloidal dispersions between liquids that do not ordinarily mix. Mayonnaise is a heterogeneous mixture of oil and vinegar. Such a mixture would quickly separate without the presence of egg yolk, which is the emulsifying agent. Other foods such as milk, margarine, and butter are also emulsions. Cosmetics, shampoos, and lotions are formulated with emulsifiers to maintain consistent quality. Table 15.4 summarizes the properties of solutions, colloids, and suspensions.

Go online to see why oil and water don't mix.

Table 15.4

Properties of Solutions, Colloids, and Suspensions

	System		
Property	**Solution**	**Colloid**	**Suspension**
Particle type	Ions, atoms, small molecules	Large molecules or particles	Large particles or aggregates
Particle size	0.1–1 nm	1–1000 nm	1000 nm and larger
Effect of light	No scattering	Exhibits Tyndall effect	Exhibits Tyndall effect
Effect of gravity	Stable, does not separate	Stable, does not separate	Unstable, sediment forms
Filtration	Particles not retained on filter	Particles not retained on filter	Particles retained on filter
Uniformity	Homogeneous	Heterogeneous	Heterogeneous

15.3 LessonCheck

18. **Describe** How does a suspension differ from a solution?

19. **Explain** What distinguishes a colloid from a suspension and a solution?

20. **Apply Concepts** How can you determine through observation that a mixture is a suspension?

21. **Explain** Could you separate a colloid by filtering? Explain.

22. **Infer** How can the Tyndall effect be used to distinguish between a colloid and a solution?

23. **Relate Cause and Effect** Can the presence of Brownian motion distinguish between a solution and a colloid? Explain.

Lesson Check Answers

18. The particles of a suspension are much larger and do not stay suspended indefinitely.

19. Colloids have particles smaller than those in suspensions and larger than those in solutions.

20. The particles in a suspension will settle out over time.

21. Particles in a colloid such as gelatin are smaller than the holes in filter paper and cannot be removed by filtering.

22. A beam of light is visible as it passes through a colloid; a beam of light is invisible as it passes through a solution.

23. Flashes of light, or scintillations, are seen when colloids are studied under a microscope. Colloids scintillate because the particles move erratically. The particles in a solution are too small to be seen under a microscope and do not cause scintillations.

Evaluate

Informal Assessment

Ask In what way are colloids similar to solutions? *(In both, dispersed particles are small enough to pass through standard filter paper and to withstand the pull of gravity.)* **Ask** In what way are colloids similar to suspensions? *(Both types of mixtures produce the Tyndall effect.)* Then have students complete the 15.3 Lesson Check.

Reteach

On the board, draw the relative sizes of solute, colloid, and suspension particles by making an analogy to golf balls, baseballs, and basketballs. Ask students to identify which "particles" would get caught in a sieve with holes a bit smaller than a basketball hoop and which particles would pass through. Remind students that solution particles are typically less than 1 nm in diameter, whereas colloid particles are ten to one thousand times as large and those of suspensions exceed the largest colloid particles.

Answers

FIGURE 5.17 Fog is a colloid that produces the Tyndall effect. Bright lights produce a higher degree of light scattering in all directions, including straight back into the driver's eyes.

Small-Scale Lab

OBJECTIVE After completing this activity, students will be able to classify compounds as electrolytes or nonelectrolytes by testing them for conductivity.

ADDRESS MISCONCEPTIONS Students often think that a substance will conduct electricity if it dissolves in water. Tell students that some covalent compounds dissolve in water but do not conduct electricity.

PREP TIME 45 minutes

CLASS TIME 20 minutes

ADVANCE PREPARATION Make up reagents as follows:

Solution	Preparation
1.0*M* HCl	82 mL of 12*M* in 1.0 L
1.0*M* HNO_3	63 mL of 15.8*M* in 1.0 L
1.0*M* H_2SO_4	56 mL of 18*M* in 1.0 L

CAUTION: *Always add acid to water.*

1.0*M* NH_3	67 mL of 15*M* in 1.0 L

CAUTION: *Using proper ventilation, add ammonia to water.*

CH_3COOH	Use white vinegar.
0.5*M* NaOH	20.0 g in 1.0 L

Obtain various liquids such as rubbing alcohol, distilled water, soft drinks, orange juice, pickle juice, and coffee.

SAFETY Be sure students wear goggles and aprons.

TEACHING TIP Ask students to bring in small samples of orange juice and other liquid foods.

EXPECTED OUTCOME None of the compounds conduct electricity when in the solid state. Aqueous solutions of NaCl, $MgSO_4$, Na_2CO_3, $NaHCO_3$, KCl, and KI conduct electricity and are thus electrolytes. Cornstarch and table sugar do not conduct electricity and are nonelectrolytes.

ANALYZE AND CONCLUDE

1. Electrolytes: NaCl, $MgSO_4$, Na_2CO_3, $NaHCO_3$, KCl, KI; nonelectrolytes: table sugar, cornstarch
2. no, because the ions are locked in a crystal lattice and cannot move
3. Table sugar and cornstarch are covalent compounds. NaCl, $MgSO_4$, Na_2CO_3, $NaHCO_3$, KCl, and KI are ionic compounds. An electrolyte is a compound that dissociates into ions in solution.
4. It must conduct electricity.

YOU'RE THE CHEMIST

1. $NaHCO_3(s) \rightarrow Na\,(aq) + HCO_3^-(aq)$
   $KCl(s) \rightarrow K\,(aq) + Cl^-(aq)$
   $MgSO_4(s) \rightarrow Mg^2\,(aq) + SO_4^{2-}(aq)$
   $KI(s) \rightarrow K\,(aq) + I^-(aq)$
   Diagrams should be similar to Figure 15.9.
2. Test each solution. Strong electrolytes: HCl, H_2SO_4, HNO_3, NaOH; Weak electrolytes: CH_3COOH, NH_3; Nonelectrolytes: rubbing alcohol, distilled water
3. Strong electrolytes: soft drinks, pickle juice
   Weak electrolytes: orange juice, coffee

Small-Scale Lab

Electrolytes

Purpose

To classify compounds as electrolytes by testing their conductivity in aqueous solution

Materials

- reaction surface
- chemicals shown in the grid below
- conductivity tester
- micropipet or dropper
- water

Procedure

1. On separate sheets of paper, draw two grids similar to the one below. Make each square 2 cm on each side.
2. Place a reaction surface over one of the grids and place a few grains of each solid in the indicated places.
3. Test each solid for conductivity.
4. Add 1 drop of water to each solid and test the wet mixture for conductivity. Be sure to clean and dry the conductivity leads between each test.

NaCl(s)	$MgSO_4(s)$
$Na_2CO_3(s)$	Table sugar $C_{12}H_{22}O_{11}$
$NaHCO_3(s)$	Cornstarch $(C_6H_{10}O_5)n$
KCl(s)	KI(s)

Analyze and Conclude

1. **Infer** Which compounds in your table are electrolytes? Which are not electrolytes?
2. **Observe** Do any of these electrolytes conduct electric current in the solid form? Explain.
3. **Classify** Identify each compound in the grid as ionic or covalent.
4. **Draw Conclusions** For a compound to be an electrolyte, what must happen when it dissolves in water?

You're the Chemist

1. **Analyze Data** When an ionic solid dissolves in water, water molecules attract the ions, causing them to come apart, or dissociate. The resulting dissolved ions are electrically charged particles that allow the solution to conduct electric current. The following chemical equations represent this phenomenon.

$$NaCl(s) \xrightarrow{H_2O} Na^+(aq) + Cl^-(aq)$$

$$Na_2CO_3(s) \xrightarrow{H_2O} 2Na^+(aq) + CO_3^{2-}(aq)$$

Write a similar chemical equation for each electrolyte you tested. Draw diagrams to explain how the ions conduct electric current.

2. **Design an Experiment** Obtain the following aqueous solutions: HCl, H_2SO_4, HNO_3, $C_2H_4O_2$, NH_3, NaOH, rubbing alcohol, and distilled water. Design and carry out an experiment to test their conductivities. Use your data to classify each substance as a strong electrolyte, weak electrolyte, or nonelectrolyte.
3. **Design an Experiment** Test various liquids for conductivity. Try soft drinks, orange juice, pickle juice, and coffee. Which liquids are electrolytes?

Focus on ELL

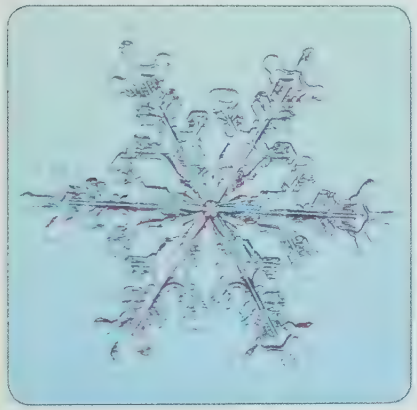
4 LANGUAGE PRODUCTION Have students work in groups of four to complete the lab. Make sure each group has ELLs of varied language proficiencies so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Provide students with a checklist for each solid. For example, if the solid is conductive, they should check yes.

INTERMEDIATE: LOW/HIGH Break down each step in the procedure into smaller steps with fewer words.

ADVANCED: LOW/HIGH Have students help classmates of lower English proficiencies with following the procedures and drawing conclusions.

15 Study Guide



BIG IDEA
BONDING AND INTERACTIONS

Water molecules are held together through hydrogen bonds. The hydrogen bonding interactions between water molecules accounts for the unique properties of water including its high surface tension, low vapor pressure, and high boiling point. Hydrogen bonding also accounts for the fact that ice is less dense than liquid water. Ionic compounds and polar covalent compounds dissolve most readily in water to form aqueous solutions. Ionic compounds dissolve in water when the polar water molecules attract the ions of the solute, causing the individual solute ions to break away from the ionic crystal.

15.1 Water and Its Properties

- Many unique and important properties of water—including its high surface tension, low vapor pressure, and high boiling point—result from hydrogen bonding.
- The structure of ice is a regular open framework of water molecules in a hexagonal arrangement.

- surface tension (490)
- surfactant (490)

15.2 Homogeneous Aqueous Systems

- Substances that dissolve most readily in water include ionic compounds and polar covalent compounds.
- All ionic compounds are electrolytes because they dissociate into ions.
- The forces holding the water molecules in hydrates are not very strong, so the water is easily lost and regained.

- aqueous solution (494)
- solvent (494)
- solute (494)
- solvation (495)
- electrolyte (496)
- nonelectrolyte (496)
- strong electrolyte (497)
- weak electrolyte (497)
- water of hydration (498)
- hydrate (498)
- anhydrous (498)
- effloresce (499)
- hygroscopic (499)
- desiccant (499)
- deliquescent (501)

Key Equation

$$\text{Percent by mass } H_2O = \frac{\text{mass of water}}{\text{mass of hydrate}} \times 100\%$$

15.3 Heterogeneous Aqueous Systems

- A suspension differs from a solution because the particles of a suspension are much larger and do not stay suspended indefinitely.
- Colloids have particles smaller than those in suspensions and larger than those in solutions.

- suspension (504)
- colloid (505)
- Tyndall effect (506)
- Brownian motion (506)
- emulsion (507)

Evaluate

Review and Assessment Materials

PROBLEM SETS Have students practice more calculations of percent by mass of water in a hydrate by using the Chapter 15 Online Problem Set.

VIRTUAL LABS Assign Electrolytes in Virtual ChemLab as an in-class or take-home assignment to reinforce the concept of electrolytes.

Study Tip

ORGANIZE NEW INFORMATION Suggest that students review the chapter content by using each of the vocabulary terms correctly in a sentence. Check their sentences for errors. Then, have students rewrite their sentences as fill-in-the-blank questions by leaving out the vocabulary terms. Students can use the questions to quiz classmates.

UbD

Understanding by Design

Performance Tasks

OH, THE SUSPENSE! Challenge students to each hypothesize whether plain yogurt is a colloid, a suspension, or a solution. Then have them develop a method to test the hypothesis. Have students write an illustrated report detailing the hypothesis, materials, methods, results, and conclusions.

WALKING ON WATER Have students research which animals have the ability to walk on the surface of water. Tell students to explain why those animals have such ability and why humans do not have this ability. Students should be sure to refer to surface tension in their answers and should present their findings to the class by using a slide-show presentation.

Focus on ELL

5 ASSESS UNDERSTANDING Assign students to complete the Standardized Test Prep. After the results of the assessment are determined, have students review the topics they scored poorly on.

BEGINNING: LOW/HIGH Have students underline the high-frequency words they understand and use context clues to eliminate distractors. Make sure students know how to correctly use an answer sheet.

INTERMEDIATE: LOW/HIGH Explain to students that they can skip a question that they do not understand immediately. Show them how to mark it so that they remember to come back to it. Remind them to skip that answer space on the answer sheet.

ADVANCED: LOW/HIGH Ask students to write out all the questions they answered incorrectly. Then have them explain in writing why they missed those questions and where to find the correct information.

ASSESSMENT

Evaluate

Answers

LESSON 15.1

24. The hydrogen atoms have a slightly positive charge. The oxygen atom has a slightly negative charge.

25. Surface molecules are attracted to the liquid molecules below but not to the air. Molecules inside the liquid are attracted in all directions.

26. Strong hydrogen bonding causes an inward pull that tends to minimize the surface area.

27. Drops are spherical; objects denser than a liquid can float on its surface.

28. A surfactant is a wetting agent such as soap or detergent. A surfactant interferes with hydrogen bonding between water molecules and reduces surface tension.

29. Hydrogen bonds hold water molecules to each other, so the tendency for them to escape the solution is low.

30. Water has a relatively low vapor pressure.

31. Water has low vapor pressure.

32. Ice is less dense than liquid water. The molecules in ice are farther apart in ice than in liquid water.

33. Hydrogen bonds between water molecules hold the molecules in a regular, open structure.

34. Ice is a regular open framework of hydrogen-bonded water molecules arranged like a honeycomb. This structure collapses in liquid water.

35. Bodies of water would freeze from the bottom up. This would kill many forms of aquatic life.

LESSON 15.2

36. An aqueous solution is a solution that has water as the solvent.

37. The solvent is the part of the solution present in the largest amount. It is the dissolving medium. The solute is the dissolved particles.

38. Solvent: water; solute: sugar

39. No; the molecules and ions are smaller than the pores of the filter, and would therefore pass through the filter.

40. Solvent molecules surround positively charged and negatively charged ions.

41. Polar water molecules electrostatically attract ions and polar covalent molecules, but nonpolar compounds are unaffected because they have no charges.

42. Water is polar, and gasoline is nonpolar.

43. **a.** HCl (polar) dissolves.
b. K_2SO_4 (ionic) dissolves
c. NaI (ionic) dissolves.
d. C_2H_6 (nonpolar) will not dissolve.
e. NH_3 (polar) dissolves.
f. $CaCO_3$ (strong ionic forces) will not dissolve.

44. ions

15 Assessment

* Solutions appear in Appendix E

Lesson by Lesson

15.1 Water and Its Properties

24. Explain why water molecules are polar.

***25.** Why do the particles at the surface of a liquid behave differently from those in the bulk of the liquid?

26. Why does water have a high surface tension?

27. Describe some observable effects that are produced by the surface tension of a liquid.

***28.** What is a surfactant? Explain how it works.

29. How can the unusually low vapor pressure of water be explained?

30. Explain why water has a relatively high boiling point.

***31.** Explain why bodies of water with large surface areas such as lakes and oceans do not evaporate rapidly.

32. What characteristic of ice distinguishes it from other solid substances?

33. Explain the role of hydrogen bonds in ice.

34. How does the structure of ice differ from the structure of water?

***35.** What would be some of the consequences if ice were denser than water?

15.2 Homogeneous Aqueous Systems

36. Distinguish between a solution in general and an aqueous solution.

37. In the formation of a solution, how does the solvent differ from the solute?

***38.** Identify the solvent and the solute in a solution of table sugar in water.

***39.** Suppose an aqueous solution contains both table sugar and table salt. Can you separate either of these solutes from the water by filtration? Explain your reasoning.

***40.** Describe the process of solvation.

41. Why is water an excellent solvent for most ionic and polar covalent compounds but not for nonpolar compounds?

42. Explain why gasoline does not dissolve in water.

***43.** Which of the following substances dissolve appreciably in water? Give reasons for your choices.
a. HCl
b. K_2SO_4
c. NaI
d. C_2H_6
e. NH_3
f. $CaCO_3$

44. What particles must be present in a solution if it is to conduct an electric current?

***45.** Why does molten sodium chloride conduct an electric current?

46. What is the main distinction between an aqueous solution of a strong electrolyte and an aqueous solution of a weak electrolyte?

47. What is meant by a substance's water of hydration?

***48.** Write formulas for these hydrates.
a. sodium sulfate decahydrate
b. calcium chloride dihydrate
c. barium hydroxide octahydrate

***49.** Name each hydrate.
a. $SnCl_4 \cdot 5H_2O$
b. $FeSO_4 \cdot 7H_2O$
c. $BaBr_2 \cdot 4H_2O$
d. $FePO_4 \cdot 4H_2O$

***50.** Epsom salt ($MgSO_4 \cdot 7H_2O$) changes to the monohydrate form at 150°C. Write an equation for this change.

51. Some hydrates are efflorescent. Explain what that means. Under what conditions will a hydrate effloresce?

***52.** Explain why a hygroscopic substance can be used as a desiccant.

53. Why is it important to keep some hygroscopic substances in tightly sealed containers?

15.3 Heterogeneous Aqueous Systems

***54.** Arrange colloids, suspensions, and solutions in order of increasing particle size.

***55.** How could you distinguish through observation among a solution, a colloid, and a suspension?

56. What is the Tyndall effect?

45. Its ions are free to move toward positively and negatively charged electrodes.

46. A strong electrolyte is almost totally ionized.

47. water in a crystal structure of a substance

48. **a.** $Na_2SO_4 \cdot 10H_2O$ **b.** $CaCl_2 \cdot 2H_2O$ **c.** $Ba(OH)_2 \cdot 8H_2O$

49. **a.** tin(IV) chloride pentahydrate
b. iron(II) sulfate heptahydrate
c. barium bromide tetrahydrate
d. iron(III) phosphate tetrahydrate

50. $MgSO_4 \cdot 7H_2O \rightarrow MgSO_4 \cdot H_2O + 6H_2O$

51. Efflorescence is the loss of water of hydration that occurs when the hydrate has a higher vapor pressure than that of the water vapor in air.

52. Hygroscopic substances absorb water vapor from the air and create a dry environment in a sealed container.

53. They absorb water vapor from the air.

LESSON 15.3

54. solutions, colloids, suspensions

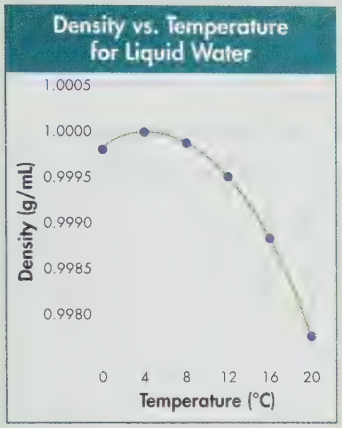
55. Colloids and suspensions exhibit the Tyndall effect but solutions do not. The particles in a suspension will settle out over time.

56. scattering of visible light by colloids and suspensions

57. Why don't solutions demonstrate the Tyndall effect?

58. What causes Brownian motion?

*59. What are two circumstances that help keep colloidal particles in suspension?



60. How can a colloid be destroyed?

61. What makes a colloidal dispersion stable?

Understand Concepts

*62. From your knowledge of intermolecular forces, arrange these liquids in order of increasing surface tension: water (H_2O), hexane (C_6H_{14}), ethanol (C_2H_6O).

*63. The graph below shows the density of water over the temperature range 0°C to 20°C.

a. What is the maximum density of water?
b. At what temperature does the maximum density of water occur?
c. Would it be meaningful to expand the smooth curve of the graph to the left to temperatures below 0°C?

64. Explain why ions become solvated in aqueous solution.

*65. Methanol (CH_4O) and hydrobromic acid (HBr) are both molecular compounds. However, an aqueous solution of methanol does not conduct an electric current, but an aqueous solution of hydrobromic acid does. Account for this difference.

*66. Explain which properties of water are responsible for these occurrences.
a. Water in tiny cracks in rocks helps break up the rocks when it freezes.
b. Water beads up on a newly waxed car.
c. A longer time is needed for a teaspoon of water to evaporate than a teaspoon of alcohol.

67. Water has its maximum density at 4°C. Discuss the consequences of this fact.

*68. Water is a polar solvent; gasoline is a nonpolar solvent. Decide which compounds are more likely to dissolve in water and which are more likely to dissolve in gasoline.
a. CCl_4
b. CH_4
c. Na_2SO_4
d. KCl

*69. You have a solution containing either table sugar or table salt dissolved in water.
a. Can you tell which it is by visual inspection? Explain.
b. Give two ways by which you could easily tell which it is.

70. Explain why ethanol (C_2H_6O) will dissolve in both gasoline and water.

71. Are all liquids soluble in each other? Explain.

*72. Write equations to show how these substances ionize or dissociate in water.
a. NH_4Cl
b. CH_3COOH
c. $Cu(NO_3)_2$
d. $HgCl_2$

*73. Name these hydrates and determine the percent by mass of water in each.
a. $Na_2CO_3 \cdot H_2O$
b. $MgSO_4 \cdot 7H_2O$

74. Calculate the percent by mass of water in calcium chloride hexahydrate ($CaCl_2 \cdot 6H_2O$).

*75. Barium hydroxide forms an octahydrate.
a. Write the equation for the formation of this hydrate from the anhydrous salt.
b. Calculate the percent by mass of water in barium hydroxide octahydrate.

*76. How many grams of copper(II) sulfate pentahydrate would you need to measure in order to have 10.0 g of anhydrous copper(II) sulfate?

77. Explain the structural difference between ice and liquid water that accounts for the lower density of ice.

Evaluate

Answers

57. The molecules or ions are too small to have reflective surfaces.
58. collisions of the molecules of the dispersing medium with the small, dispersed colloidal particles
59. Brownian motion and repulsion between like-charged ions adsorbed on the surfaces of colloidal particles.
61. the addition of an emulsifier

UNDERSTAND CONCEPTS

62. hexane, ethanol, water
63. **a.** 1.0000 g/mL
b. 4°C
c. No; there would be a break in the curve at 0°C as liquid water at 0°C changes to ice at 0°C.
64. Anions are attracted to the hydrogen atoms of the water molecule because they have a partial positive charge. Cations are attracted to the oxygen atom in the water molecule because it has a partial negative charge.
65. Hydrobromic acid disassociates into hydrogen and bromide ions when dissolved in water, but methanol does not.
66. **a.** Water expands when it freezes to ice.
b. Water is polar and wax is nonpolar, and water has a higher surface tension.
c. Water has a lower vapor pressure than alcohol.
67. Water molecules have maximum density at 4°C. Below 4°C the molecules arrange in a regular network because of the attractions between them. As a result, ice has a lower density than water.
68. **a.** gasoline **b.** gasoline **c.** water **d.** water
69. **a.** No, both form clear, colorless solutions.
b. Evaporate the water to examine the crystals; test for electrical conductivity; do a flame test
70. Ethanol has both a polar hydroxyl end (–OH) that dissolves in water and a nonpolar hydrocarbon end (C_2H_5–) that dissolves in gasoline.
71. No; nonpolar molecules do not dissolve in polar solvents.
72. **a.** $NH_4Cl(s) \rightarrow NH_4^+(aq) + Cl^-(aq)$
b. $C_2H_4O_2(s) \rightarrow H^+(aq) + C_2H_3O_2^-(aq)$
c. $Cu(NO_2)_2(s) \rightarrow Cu^{2+}(aq) + 2NO_2^-(aq)$
d. $HgCl_2(s) \rightarrow Hg^{2+}(aq) + 2Cl^-(aq)$
73. **a.** sodium carbonate monohydrate, 14.5% H_2O
b. magnesium sulfate heptahydrate, 51.1% H_2O
74. 8.2% H_2O
75. **a.** $Ba(OH)_2(s) + 8H_2O(l) \rightarrow Ba(OH)_2 \cdot 8H_2O(s)$
b. 45.7% H_2O
76. 15.6 g $CuSO_4 \cdot 5H_2O$
77. The molecules in ice are further apart than the molecules in liquid water.

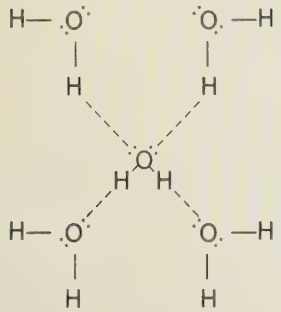
Answers

78. **a.** (1), (3), (6), (8) **b.** (1), (2), (5), (6), (7), (9) **c.** (2), (4), (5)



79. The Tyndall Effect

80. **a.** nonelectrolyte **b.** weak electrolyte **c.** strong electrolyte

THINK CRITICALLY

81. The container would break because water expands as it freezes.

82.

83. The surface tension of water keeps the strider from sinking. The surfactant would reduce the surface tension and the strider would shrink.

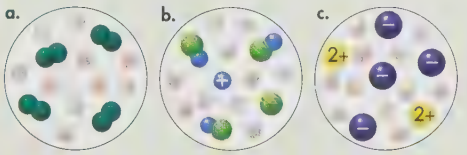
84. Ice would form on top and sink to the bottom. The pond would freeze more quickly because no surface ice would insulate the water below from the freezing air.

85. The hydrogen-bonded structures in liquid water are disrupted when ethyl alcohol is added because the alcohol competes for hydrogen bonds with water molecules and the water structure collapses. Thus, mixtures of water and ethyl alcohol have less volume than the sum of the volumes of the components. Mixing two liquids could result in a volume greater than the sum of the volumes of the components if the structural ordering in the mixture is greater than in the separated components.

86. Most of the important chemical reactions of life take place in aqueous solutions inside cells.

87. The liquid would form a layer on top of the water if its density was less than that of water and on the bottom if its density was greater. The mixture would form a temporary emulsion.

88. Solid A is potassium nitrate. Solid B is barium sulfate. Solid C is fructose.



*78. Match each term with the following descriptions. A description may apply to more than one term.

a. solution **b.** colloid **c.** suspension

(1) does not settle out on standing
(2) heterogeneous mixture
(3) particle size less than 1 nm
(4) particles can be filtered out
(5) demonstrates the Tyndall effect
(6) particles are invisible to the unaided eye
(7) homogenized milk
(8) saltwater
(9) jelly

79. A student standing in front of a murky aquarium sees a sharply focused flashlight beam shining through the aquarium as only a broad, diffuse light. What phenomenon is the student observing?

*80. The diagrams below represent aqueous solutions of three different substances. Identify each substance as a strong electrolyte, weak electrolyte, or nonelectrolyte.

Think Critically

*81. **Predict** Describe what might happen if you put a sealed glass container full of water into a freezer.

82. **Use Models** Make a drawing to show how one molecule of water can be connected to as many as four other molecules of water by hydrogen bonds. Write an explanation of your drawing.

*83. **Relate Cause and Effect** A water strider is an insect with elongated legs that can easily walk on the surface of water. What would you expect to happen to the insect if a small amount of a surfactant were added to the water? Explain the reasoning behind your answer.

84. **Predict** Describe what would happen to a pond at 0°C if the density of ice were greater than the density of water. Do you think the pond would freeze more quickly? Explain.

*85. **Infer** When ethanol (C_2H_6O) dissolves in water, the volume of the final solution is less than the separate volumes of the water and alcohol added together. Can you explain this result? Do you think that it might be possible to mix two different liquids and get a mixture volume that is larger than the sum of the volumes of the two components? Explain.

*86. **Draw Conclusions** When the humidity is low and the temperature high, humans must take in large quantities of water or face serious dehydration. Why do you think water is so important for the proper functioning of your body?

87. **Apply Concepts** Describe as specifically as possible what would happen if a nonpolar molecular liquid were added to water. What would form if you shook this mixture vigorously?

88. **Analyze Data** You are given three white solids: A, B, and C. You know that one of the solids must be fructose ($C_6H_{12}O_6$), one must be potassium nitrate (KNO_3), and one must be barium sulfate ($BaSO_4$). Solid A dissolves in water and the resulting solution conducts an electric current. Solid B is insoluble. Solid C dissolves in water and the resulting solution does not conduct an electric current. Identify the solids A, B, and C.

*89. **Infer** Cobalt(II) chloride test paper is blue. This paper is made by soaking strips of paper in an aqueous solution of $CoCl_2 \cdot 6H_2O$. The paper strips are then dried in an oven.

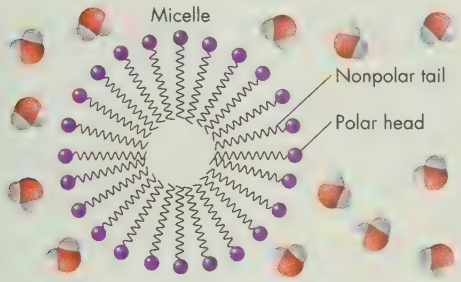
$$\underset{\text{pink}}{CoCl_2 \cdot 6H_2O} \xrightarrow{\text{heat}} \underset{\text{blue}}{CoCl_2} + 6H_2O$$

a. When cobalt(II) chloride hexahydrate is dissolved in water, what is the color of the solution?
b. What is the color of wet cobalt(II) chloride paper?
c. What is the color of dry cobalt(II) chloride paper?
d. What is the percent by mass of water in the hexahydrate?
e. What does cobalt(II) chloride test paper test for?

Enrichment

90. **Compare** How do the volumes of the following compare?

a. 1 g of ice at 0°C and 1 g of liquid water at 0°C



b. 1 g of liquid water at 100°C and 1 g of steam at 100°C

***91.** **Relate Cause and Effect** When spring comes, ice melting at the surface of a pond begins a beneficial process that stirs up the water of the pond. Explain why the pond water begins to mix when the ice melts. (*Hint:* Consider the changes in density.)

***92.** **Infer** A problem for firefighters is that much of the water they spray on a fire doesn't soak in but runs off carrying debris and pollution into the environment. Explain how the addition of a surfactant to water used to fight fires could help put out the fire more rapidly and protect the environment.

***93.** **Relate Cause and Effect** After a winter of alternate periods of freezing and thawing, some roads have broken pavement and potholes. Using what you know of the properties of water, explain why potholes form.

94. **Interpret Diagrams** Detergents consist of molecules with a polar or charged head and a long, oil-like tail. In water, detergent molecules can aggregate into organized structures called micelles. As shown below, the polar heads face the water molecules and the oily chains are inside the micelle. Suggest an explanation for the formation of micelles.

Write About Science

95. **Explain** Research the importance of electrolytes in the body. Write a paragraph explaining why the concentration of these ions may decline and how they can be restored.

96. **Research** Clothes dryer sheets are often added to tumble dryers to prevent clothes from wrinkling. Do research to learn what compounds are used in dryer sheets and how they work. Write a brief report of your findings.

CHEMYSTERY

Coming Clean

Wes's dirty socks finally did become clean, but only after being thrown into the washing machine with a load of his family's laundry. It's not just the machine that did the trick. It was also the laundry detergent that was added to the load.

Water alone cannot remove many common stains. The particles of dirt and grease on Wes's socks were trapped in the cloth fibers and could not be dissolved by water. Also, because of its high surface tension, the water could not penetrate the fibers. Laundry detergents typically contain one or more surfactants. The surfactants reduce the surface tension of water, so that it can effectively wet and penetrate the fibers. The surfactants also act as emulsifiers. One end of the surfactant molecule is nonpolar and can dissolve the molecules in dirt and grease. The other end of the surfactant molecule is polar and can dissolve in water. Agitation provided by the washing machine helps pull the stain free from the cloth fibers.

***97.** **Infer** What happens to the molecules in the dirt and grease once they are lifted from the cloth fibers?

98. **Connect to the BIG IDEA** Explain how detergents remove stains from clothing by describing the interactions among the molecules in the detergent, the molecules in the stain, and the water molecules.

CHEMYSTERY

START A CONVERSATION After students have read through the CHEMystery, engage students in a discussion of the properties of water, dirt, and grease that prevented Wes from being able to clean his socks with just water. **Ask** Why wasn't Wes able to remove the dirt and grease by using plain water? *(Dirt and grease are nonpolar. Water is polar. Water will easily dissolve only polar compounds.)* **Ask** Would the surfactant be more or less effective in removing the dirt and grease if both ends of it were polar? Why? *(It would be less effective. One end needs to be nonpolar to dissolve the nonpolar dirt and grease.)*

CHEMYSTERY ANSWERS

96. Fabrics build up electrostatic charges from rubbing against one another in the dryer. Fabrics cling to each other and wrinkle as a result. Dryer sheets are saturated with a liquid surfactant. One side of the surfactant molecule has a positively charge atom that bonds to the surface of negatively charged fabrics. The other side of the surfactant molecule is a long chain fatty material such as a fatty acid or alcohol. The fatty material leaves the surface of the fabric slightly oily preventing the build-up of electrostatic charges.

97. The molecules in the dirt and grease dissolve in the water.

ASSESSMENT

Answers

ENRICHMENT

89. **a.** pink **b.** pink **c.** blue **d.** 45.4 % H_2O **e.** water or water vapor

90. **a.** The volume of 1 g of ice at 0°C is greater. **b.** The volume of 1 g of liquid water at 100°C is less.

91. In spring, when the ice melts and the temperature of the surface water increases to 4°C, it becomes heavier than the water below it and sinks. The downward movement of surface water forces water in the deeper parts of the lake upward, where it is warmed.

92. A surfactant helps to wet the burning material, so less water is needed to put out the fire. Thus, less water carries pollutants into the environment.

93. Water enters cracks in pavement and expands when it freezes, creating larger cracks. Continuous freeze-thaw cycles cause pavement to break up and form potholes.

WRITE ABOUT SCIENCE

94. The polar heads are attracted to the water molecules so they line up on the outside of the micelle. The nonpolar tails are not attracted to the water molecules, so they shift to the inside of the micelle.

95. Electrolytes are essential to all metabolic processes. Electrolytes are lost through diarrhea, vomiting and sweating. Sport drinks are a good source of electrolytes.

CUMULATIVE REVIEW

98. Dirt and grease contain nonpolar molecules. One end of the surfactant molecules in detergent is nonpolar and can dissolve the dirt and grease. The other end of the surfactant molecules is polar and can dissolve in the polar molecules of water.

99. **a.** 195 g **b.** 1.95×10^5 mg **c.** 0.195 kg

100. **a.** 5 **b.** 2 **c.** 2 **d.** 4

101. $1s^2 2s^2 2p^6$, neon

102. $H^+ + H:\ddot{O}:H \longrightarrow H:\underset{\displaystyle H}{\ddot{O}}:H^+$

103. **a.** 22.4 L.
b. mass He: 4.00 g; mass CH_4: 16.0 g; mass O_2: 32.0 g
c. density He: 0.179 g/L; density CH_4: 0.716 g/L; density O_2: 1.43 g/L
d. Balloons containing He and CH_4 will rise; O_2 balloon will sink.

104. **a.** $6CO_2(g) + 6H_2O(l) \rightarrow C_6H_{12}O_6(s) + 6O_2(g)$
b. $2Na(s) + 2H_2O(l) \rightarrow 2Na + (aq) + 2OH^-(aq) + H_2(g)$

105. 9.07 g H_2; 72.0 g O_2

106. 0.0360 g H_2O, 0.0224 L O_2

107. 636 g C_2H_4O

108. **a.** 0.300 mol O_2 **b.** 6.72 L O_2

109. **a.** hydrogen **b.** 0.048 g H_2O **c.** oxygen **d.** 0.010 L

110. **a.** raises the boiling point
b. lowers the boiling point

111. 1.27 atm

Cumulative Review

99. A cylindrical vessel, 28.0 cm in height and 3.00 cm in diameter, is filled with water at 50°C. The density of water is 0.988 g/cm³ at this temperature. Express the mass of water in the vessel in the following units.

a. grams **b.** milligrams **c.** kilograms

***100.** How many significant figures are in each measurement?

a. 56.003 g
b. 750 mL
c. 0.0056 cm
d. 0.4005 dg

101. Write the correct electron configuration for the oxide ion. Which noble gas has the same electron configuration?

***102.** When a proton is attracted to the unshared electron pair of a water molecule, the polyatomic hydronium ion (H_3O^+) is formed. Draw electron dot structures to show the formation of this ion.

103. The balloons contain 1 mol of He, CH_4, and O_2 at STP.

a. What is the volume of each balloon?
b. What is the mass of the gas in each balloon?
c. Calculate the density of the gas in each balloon.
d. The density of air at room temperature is about 1.2 g/mL. Predict whether each balloon will rise or sink when released.

***104.** Balance the following equations.

a. $CO_2(g) + H_2O(l) \longrightarrow C_6H_{12}O_6(s) + O_2(g)$
b. $Na(s) + H_2O(l) \longrightarrow Na^+(aq) + OH^-(aq) + H_2(g)$

105. How many grams each of hydrogen gas and oxygen gas are required to produce 4.50 mol of water?

***106.** The decomposition of hydrogen peroxide is given by this equation.

$$2H_2O_2(l) \longrightarrow 2H_2O(l) + O_2(g)$$

Calculate the mass of water and the volume of oxygen at STP formed when 2.00×10^{-3} mol of hydrogen peroxide is decomposed.

***107.** Acetaldehyde (C_2H_4O) is produced commercially by the reaction of acetylene (C_2H_2) with water, as shown by this equation.

$$C_2H_2(g) + H_2O(l) \longrightarrow C_2H_4O(l)$$

How many grams of C_2H_4O can be produced from 2.60×10^2 g H_2O, assuming sufficient C_2H_2 is present?

108. Hydrogen reacts with oxygen to form water.

$$2H_2(g) + O_2(g) \longrightarrow 2H_2O(l)$$

a. How many moles of oxygen are required to produce 10.8 g H_2O?
b. How many liters of oxygen is this at STP?

***109.** A mixture of 40 cm³ of oxygen gas and 60 cm³ of hydrogen gas at STP is ignited.

a. Which gas is the limiting reagent?
b. What is the mass of water produced?
c. Which gas remains after reaction?
d. What is the volume, at STP, of the remaining gas?

110. Explain how the following changes in the pressure on the surface of water affect the water's boiling point.

a. an increase in pressure
b. a decrease in pressure

***111.** The temperature of 1 L of steam at constant volume and 1.00 atm pressure is increased from 100°C to 200°C. Calculate the final pressure of the steam in atmospheres, assuming the volume does not change.

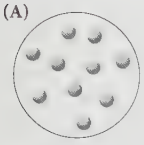
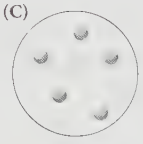
Standardized Test Prep for Indiana

Standard: C.7.1



Select the choice that best answers each question or completes each statement.

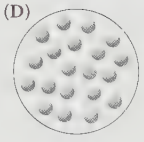
1. When a sugar cube completely dissolves in a glass of water, it forms
   (A) a colloid. (C) an emulsion.
   (B) a suspension. (D) a solution.
2. How many water molecules are tied up per formula unit of a compound that is an octahydrate?
   (A) nine (B) eight (C) seven (D) six
3. Which property is characteristic of water?
   (A) relatively high surface tension
   (B) relatively high vapor pressure
   (C) relatively low solvent ability
   (D) relatively low polarity



Use the atomic windows to answer Question 4.

4. Atomic window (A) represents solute particles in a given volume of solution. Which window represents the solute particles in the same volume of solution when the amount of solvent is doubled?

(A)



(C)

(B)

(D)

Tips for Success

Constructed Response You will probably answer most constructed response questions by writing a sentence or a paragraph. Put as much information into your answer as possible, but avoid unnecessary words. Be sure to address all the points asked for in the question.

Use the description and the data table to answer Questions 5–7.

A student measured the conductivity of six aqueous solutions. Each solution had equal concentrations of solute. The magnitude of the conductivity value is proportional to the number of ions in the solution. The SI conductivity unit is the microsiemens/cm (μS/cm). The table gives the student's results.

Solution	Conductivity (μS/cm)
Potassium chloride, KCl	2050
Aluminum chloride, $AlCl_3$	4500
Calcium chloride, $CaCl_2$	3540
Sodium hydroxide, NaOH	2180
Ethanol, C_2H_6O	0
Magnesium bromide, $MgBr_2$	3490

5. Why does the ethanol solution have zero conductivity?
6. Explain why two pairs of conducting solutions have similar conductivities.
7. The $AlCl_3$ solution has a conductivity that is about twice that of the KCl solution. Explain.

For each question there are two statements. Decide whether each statement is true or false. Then decide whether Statement II is a correct explanation for Statement I.

	Statement I		Statement II
8.	Water has a relatively high surface tension.	BECAUSE	Water molecules form strong hydrogen bonds with other water molecules.
9.	Particles in a colloid settle out faster than particles in a solution.	BECAUSE	Particles in a colloid are larger than particles in a solution.
10.	Water molecules are polar.	BECAUSE	The bond between hydrogen and oxygen atoms in a water molecule is polar.

Materials List

For the Student

Quick Lab, p 519
- sodium hydrogen carbonate
- cornstarch
- stirring rod
- distilled water
- flashlight
- masking tape
- 3 jars with parallel sides
- teaspoon cup

Small-Scale Lab, p 545
- NaCl (lab grade)
- water
- 50-mL volumetric flask
- balance

For the Teacher

Teacher Demo, p 522
- bottle of warm soda
- bottle of cold soda
- 2 other bottles of soda

Class Activity, p 527
- water, NaCl, sucrose
- 50-mL, 100-mL, and 1-L volumetric flasks
- balance
- graph paper

Class Activity, p 528
- calculator

Teacher Demo, p 530
- four 20-mL test tubes
- 10 mL of 0.5*M* sucrose
- 15 mL water
- 10-mL pipet

Class Activity, p 536
- ice
- water
- rock salt
- thermometer
- foam cup

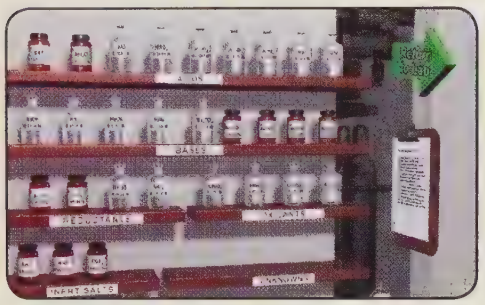
Changing Boiling and Freezing Points



What's Online

CHEM TUTOR Students access guided, step-by-step tutorials for solving problems involving Henry's law, solution concentration, and freezing-point depression.

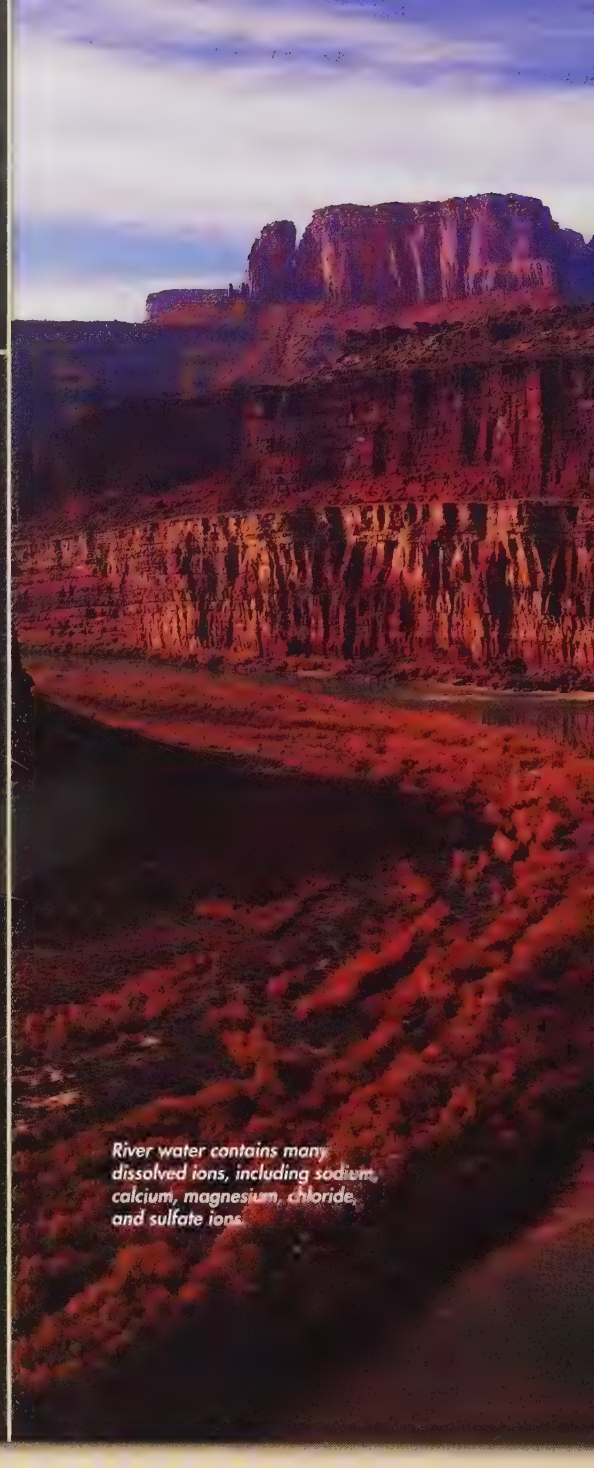
ONLINE PROBLEMS Students can practice key problem-solving skills in an online problem set.

MATH HELP Identify the students who struggle with math by assigning an online math skills diagnostic test. These students can then improve and practice math skills using the MathXL tutorial system.

VIRTUAL LAB Students go on an animated virtual lab tour in which colligative properties are studied in a simulated laboratory environment.

KINETIC ART Students can interact with animations involving saturated solutions and vapor pressure.

CONCEPTS IN ACTION Students watch an overview of a key chapter concept using real-world contexts and concrete examples and analogies. Each activity includes an interactive animation followed by analysis questions.



16 Solutions

IN ACADEMIC STANDARDS for SCIENCE

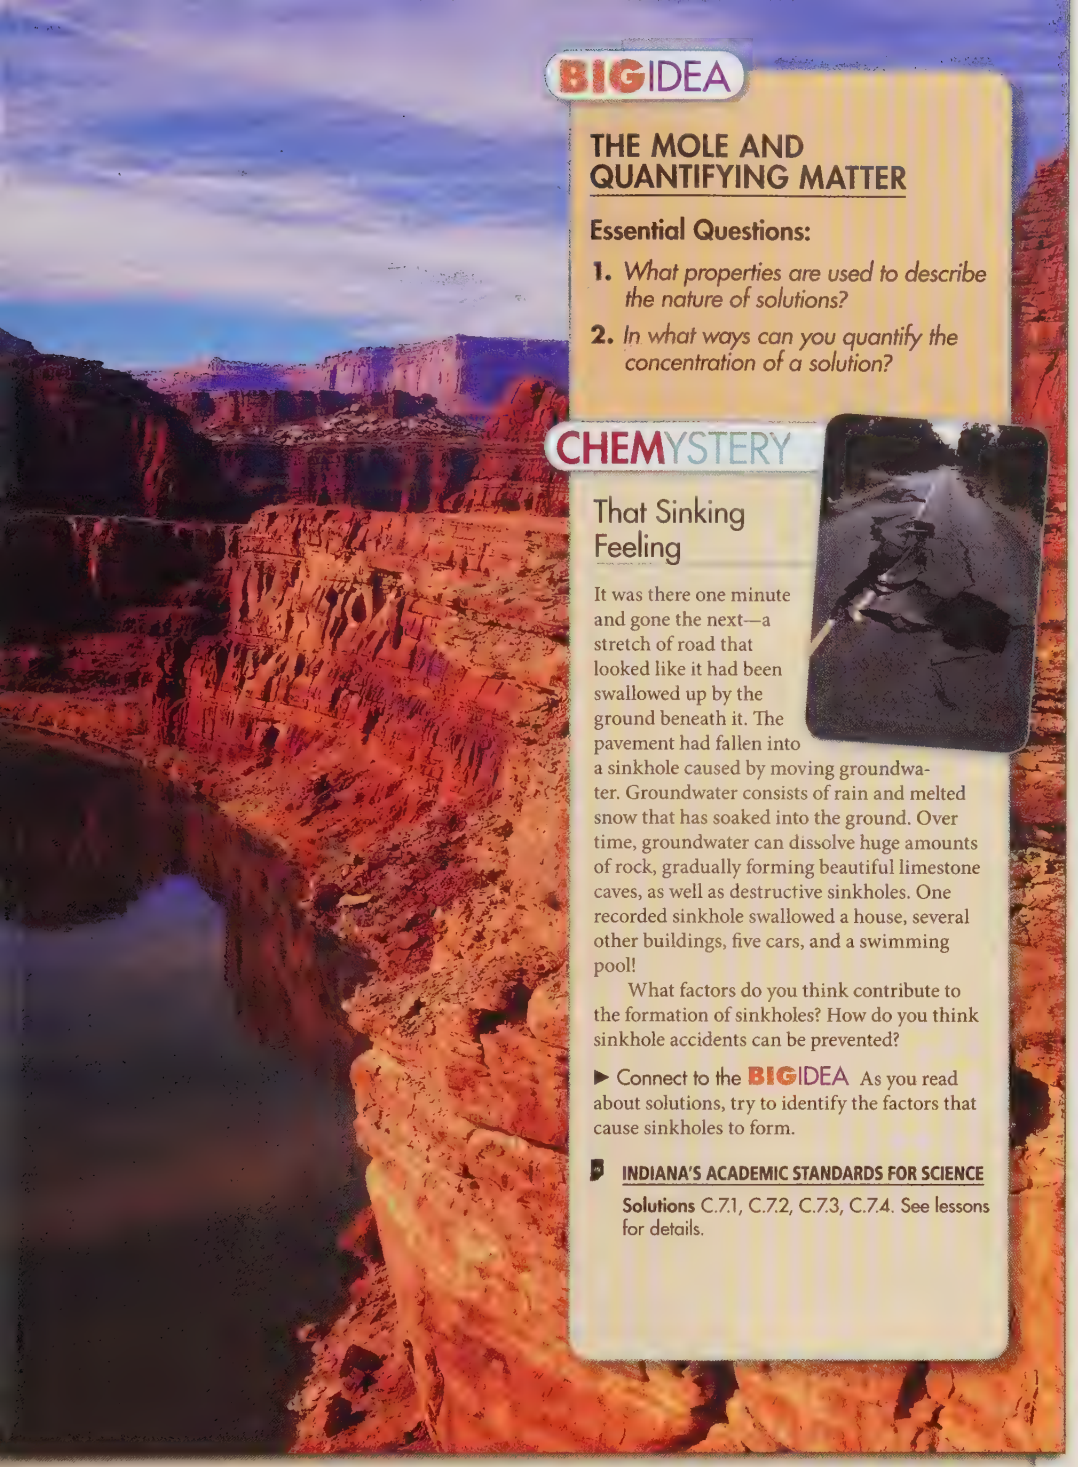
Nature of Science

- Recognize that their explanations must be based both on their data and other known information from investigations of others.
- Apply standard techniques in laboratory investigations to measure physical quantities in appropriate units and convert known quantities to other units as necessary.

Solutions

C.7.1 Describe the composition and properties of types of solutions.

Also covered C.7.2, C.7.3, C.7.4



Focus on ELL

1 CONTENT AND LANGUAGE Begin the class by focusing students' attention on the words *solutions, concentrations,* and *colligative properties* in the lesson titles. Write the words on the board along with their phonetic spellings and pronounce them slowly. Group students in threes and have them create a KWL chart for each word. Have them list details for the first two columns. Instruct groups to complete the last column after they read the lesson.

BEGINNING: LOW/HIGH HIGH Ask students to volunteer to explain aloud their KWL chart, in English or in the students' native language.

INTERMEDIATE: LOW/HIGH Verbally brainstorm questions for the *W* column based on the chapter opener photo and CHEMystery.

ADVANCED: LOW/HIGH Have students teach the words to less proficient students, using a creative and appropriate medium to show how the words are related.

BIGIDEA

THE MOLE AND QUANTIFYING MATTER

Essential Questions:

1. *What properties are used to describe the nature of solutions?*
2. *In what ways can you quantify the concentration of a solution?*

CHEMYSTERY

That Sinking Feeling

It was there one minute and gone the next—a stretch of road that looked like it had been swallowed up by the ground beneath it. The pavement had fallen into a sinkhole caused by moving groundwater. Groundwater consists of rain and melted snow that has soaked into the ground. Over time, groundwater can dissolve huge amounts of rock, gradually forming beautiful limestone caves, as well as destructive sinkholes. One recorded sinkhole swallowed a house, several other buildings, five cars, and a swimming pool!

What factors do you think contribute to the formation of sinkholes? How do you think sinkhole accidents can be prevented?

▶ Connect to the BIGIDEA As you read about solutions, try to identify the factors that cause sinkholes to form.

INDIANA'S ACADEMIC STANDARDS FOR SCIENCE

Solutions C.7.1, C.7.2, C.7.3, C.7.4. See lessons for details.

Introduce the Chapter

IDENTIFYING PRECONCEPTIONS Students may believe that dissolution is an all-or-none process. Use the activity to introduce the idea that the ability of one substance to dissolve in another depends on various factors.

Activity *Each pair of students will need 2 beakers (about 100 mL), 2 plastic spoons, warm and cold water, and sugar.* Have one student in a group half-fill a beaker with warm water and the other half-fill a beaker with cold water. Have the students stir sugar, one spoonful at a time, into the water. Students should compare how fast it dissolves in the cold and warm water, and the total amount that will dissolve. Repeat the activity, having students use water at the same temperature, but stirring at different rates.

UbD

Understanding by Design

Students are building toward an understanding of solutions, by applying the mole concept and dimensional- analysis skills.

PERFORMANCE GOALS At the end of Chapter 16, students will be able to answer the essential questions by applying their knowledge of solutions. Students will also be able to perform calculations involving colligative properties of solutions.

ESSENTIAL QUESTIONS Read the essential questions aloud. **Ask** If you have a solution of salt water, what is the solute and what is the solvent? *(Salt is the solute. Water is the solvent.)* **Ask** Are the parts of a solution chemically or physically combined? *(Physically; the components of a solution are physically mixed, not chemically bonded together.)*

BIGIDEA Use the photo of the Colorado River canyon to help students connect to the concepts they will learn in this chapter. Activate prior knowledge by having students describe similar places (such as a river valley or creek bed) that they have visited. **Ask** Why are the sides of the canyon vertical? *(The water has worn them down.)* **Ask** What do you think happened to the minerals in the rock? *(Some dissolved in the water; others broke loose into small fragments due to the abrasive action of the river water. In either case, the moving water transported the minerals downstream.)* Point out that you could describe the concentration of minerals in the water if you knew how much of each mineral was in a certain quantity of river water.

CHEMYSTERY Have students read over the CHEMystery. Connect the CHEMystery to the Big Idea of The Mole and Quantifying Matter by explaining that various factors may affect the ability of one substance to dissolve in another. Point out that, just as river in the photo can dissolve minerals in rock near the surface, groundwater can dissolve minerals underground. Have students describe what happens if they stir salt into water. Then, as a hint to solving the CHEMystery, have them think what would happen if soluble minerals such as salt were in the underground rock.

LESSON 16.1

Key Objectives

16.1.1 IDENTIFY the factors that affect how fast a substance dissolves.

16.1.2 DESCRIBE the equilibrium in a saturated solution.

16.1.3 DESCRIBE the factors affect the solubility of a substance.

PearsonChem.com

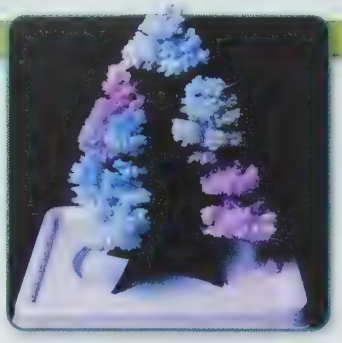
Engage

CHEMISTRY & YOU Instruct students to read the opening text and to examine the photo. Encourage students to share experiences with crystal-growing kits or making rock candy. **Ask** What do these processes have in common with the one shown in the photo? *(They each start with a heated solution.)*

Activate Prior Knowledge

Engage students in a discussion about the process of making instant hot chocolate. Elicit that the hot water is poured over the particles of hot chocolate mix, and then stirred to aid in the dissolving of the mix. Explain that students will use their knowledge of creating solutions, such as hot chocolate or lemonade, to learn about the properties of chemical solutions.

IN ACADEMIC STANDARDS for SCIENCE



- Develop explanations based on reproducible data and observations gathered during laboratory investigations.

C.7.1 Describe the composition and properties of types of solutions.

C.7.2 Explain how temperature, pressure and polarity of the solvent affect the solubility of a solute.

16.1 Properties of Solutions

C.7.1 Composition and properties of solutions; C.7.2 Factors affecting solubility

CHEMISTRY & YOU

Q: *How can you grow a tree made out of crystals?* You're already familiar with the concept of liquids freezing. But what about crystals growing from a solution? The crystallization of a solute from solution is a physical change that is different from freezing. The crystal tree shown here began its "life" as an ordinary aqueous solution. The tree trunk, made of absorbent paper, soaks up the liquid. As water evaporates from the solution, the solutes crystallize onto the paper, forming delicate "leaves." Not all solutions will crystallize as this one did. The rate of crystallization depends on the nature of the solute and solvent, as well as on the temperature and humidity of the surroundings.

Key Questions

What factors affect how fast a substance dissolves?

How can you describe the equilibrium in a saturated solution?

What factors affect the solubility of a substance?

Vocabulary

- saturated solution
- solubility
- unsaturated solution
- miscible
- immiscible
- supersaturated solution
- Henry's law

Solution Formation

What factors affect how fast a substance dissolves?

Have you noticed, when making tea, that granulated sugar dissolves faster than sugar cubes, and that both granulated sugar and sugar cubes dissolve faster in hot tea or when you stir the tea? Figure 16.1 illustrates these observations. You will be able to explain these observations once you have gained an understanding of the properties of solutions.

Recall that solutions are homogeneous mixtures that may be solid, liquid, or gaseous. The compositions of the solvent and the solute determine whether or not a substance will dissolve. **Factors that affect how fast a substance dissolves include agitation, temperature, and the particle size of the solute.** Each of these factors involves the contact of the solute with the solvent.

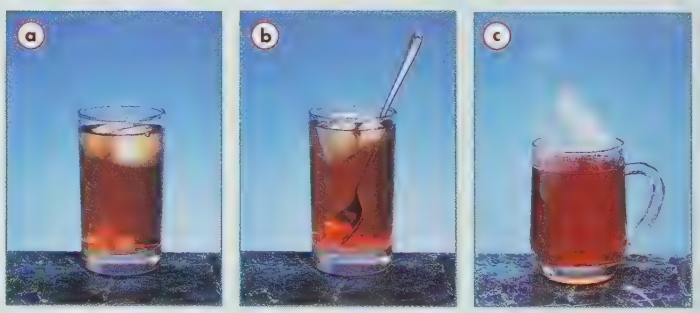


Figure 16.1 Dissolving Sugar Stirring and heating increase the rate at which a solute dissolves. **a.** A cube of sugar in cold tea dissolves slowly. **b.** Granulated sugar dissolves in cold water more quickly than a sugar cube, especially with stirring. **c.** Granulated sugar dissolves very quickly in hot tea.

Focus on ELL

1 CONTENT AND LANGUAGE Divide the class into seven groups; assign one vocabulary word to each group. Instruct each group to pronounce, define, create a visual example, and create a picture or symbol of their word. Have each group teach their word to the class.

2 FRONTLOAD THE LESSON Ask students to describe the places in their native countries where crystals form naturally, such as shorelines and caves. Allow time for students to share information about their country that explains why the formation of crystals does or does not occur, such as particular climatic or geologic conditions.

3 COMPREHENSIBLE INPUT Physically demonstrate the examples of dissolution described in the Solution Formation section. Use the formation of rock candy on a string to supplement the Kinetic Art animation of a saturated solution.

Agitation If a teaspoon of granulated sugar (sucrose) is placed in a glass of tea, the crystals dissolve slowly. If the contents of the glass are stirred, however, the crystals dissolve more quickly. The dissolving process occurs at the surface of the sugar crystals. Stirring speeds up the process because fresh solvent (the water in tea) is continually brought into contact with the surface of the solute (sugar). It's important to realize, however, that agitation (stirring or shaking) affects only the rate at which a solid solute dissolves. It does not influence the amount of solute that will dissolve. An insoluble substance remains undissolved regardless of how vigorously or for how long the solvent/solute system is agitated.

Temperature Temperature also influences the rate at which a solute dissolves. Sugar dissolves much more rapidly in hot tea than in iced tea. At higher temperatures, the kinetic energy of water molecules is greater than at lower temperatures, so the molecules move faster. The more rapid motion of the solvent molecules leads to an increase in the frequency and the force of the collisions between water molecules and the surfaces of the sugar crystals.

Particle Size of the Solute The rate at which a solute dissolves also depends upon the size of the solute particles. A spoonful of granulated sugar dissolves more quickly than a sugar cube because the smaller particles in granulated sugar expose a much greater surface area to the colliding water molecules. Remember, the dissolving process is a surface phenomenon. The more surface area of the solute that is exposed, the faster the rate of dissolving.

QuickLab

Solutions and Colloids

Purpose To classify mixtures as solutions or colloids using the Tyndall effect

Materials

- sodium hydrogen carbonate
- cornstarch
- stirring rod
- distilled water (or tap water)
- flashlight
- masking tape
- 3 jars with parallel sides
- teaspoon
- cup

Procedure

1. In a cup, make a paste: Mix one-half teaspoon of cornstarch with 4 teaspoons of water.
2. Fill one jar with water. Add one-half teaspoon of sodium hydrogen carbonate to a second jar and fill with water. Stir to mix. Add the cornstarch paste to the third jar and fill with water. Stir to mix.
3. Turn out the lights in the room. Shine the beam of light from the flashlight at each of the jars and record your observations.

Analyze and Conclude

1. **Observe** In which of the jars in the experiment was it possible to see the path of the beam of light?
2. **Infer** What made the light beam visible?
3. **Explain** If a system that made the light beam visible were filtered, would the light beam be visible in the filtrate? Explain your answer.
4. **Predict** What would you observe if you were to replace the sodium hydrogen carbonate with sucrose (cane sugar) or sodium chloride (table salt)? If you were to replace the cornstarch with flour or diluted milk?

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in pairs to complete the Quick lab. Make sure students are paired so that more proficient students can help less proficient ones.

BEGINNING

LOW Model the procedure and have students repeat your actions.

HIGH Have students draw a picture or use symbols to note their observations.

INTERMEDIATE: LOW/HIGH Ask students to answer the questions in Analyze and Conclude aloud.

ADVANCED: LOW/HIGH Have students create a pictorial procedure that students can follow to test their predictions made in question 4 of the Quick Lab.

Foundations for Reading

BUILD VOCABULARY Have students create a compare/contrast table to compare the following solution types: *saturated*, *unsaturated*, and *supersaturated*. Have them include definitions and examples of each solution type. Encourage students to draw a sketch to depict each word.

READING STRATEGY For each section, have students identify three things they learned, two things they found particularly interesting, and one question they have after reading the text.

Explain

Solution Formation

MAKE A CONNECTION Prepare a bulletin board display using pictures that illustrate the importance of solution processes in nature. Examples include a farmer applying fertilizer to a field, a person eating food, fish swimming, or a volcano erupting. Encourage students to contribute to the display by posting pictures they find in periodicals and newspapers, or with pictures they have taken themselves.

Explore

QuickLab

OBJECTIVE After completing this activity, students will be able to classify mixtures as solutions or colloids using the Tyndall effect.

SKILLS FOCUS observing, inferring, predicting

PREP TIME 30 minutes

CLASS TIME 20 minutes

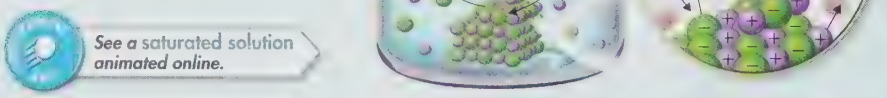
EXPECTED OUTCOME The beam of light is visible in the cornstarch/water mixture but not in water or sodium hydrogen carbonate solution.

ANALYZE AND CONCLUDE

1. undissolved cornstarch
2. Cornstarch particles reflect light.
3. yes for a colloid; no for a suspension
4. Sucrose and sodium chloride are both soluble in water, so the beam of light would not be visible in either of the resulting solutions. Flour and milk do not dissolve in water (flour and water form a suspension; milk and water form a colloid), so the beam of light would be visible in either mixture.

FOR ENRICHMENT Have students test and classify various household mixtures using the Tyndall effect.

Explain



Solubility

USE AN ANALOGY Use the concept of population density to help convey the meaning of solubility. Both population density and solubility are quantities that describe concentration using derived units. Population density, typically means the number of individuals per unit area—for example, persons per square kilometer, birds per square mile (of land), or fish per hectare (of water surface). Provide pictorial representations to visually convey the population density of a species for a given area or territory. Then explain how this concept is analogous to solubility by relating the individuals within the population to the molecules or ions dissolved in a given quantity of solvent. Point out that the precise amount of solute that a particular solvent holds under given conditions is fixed. Population density is not limited in the same way; that is, even under stable conditions, a population may still undergo a net gain or loss. However, in the long term, there is in fact a maximum population that a given amount of land or water can sustain (this is known as carrying capacity).

USE AN ANALOGY Equilibrium may be a difficult concept for some students to comprehend. Emphasize the dynamic nature of saturation. Point out that initially, salt readily dissolves in water because the ions can be solvated by available water molecules. Explain that the number of solvated ion-complexes that can inhabit a given volume of water is limited, however. If more ions are to join in the solvation, some ions must give up their places. Use substitutions in a basketball game as an analogy for the dynamic nature of saturation. Explain that in basketball only five players from each team can be on the court at one time. A player on the bench cannot enter the game until a player from the same team comes off the court. Convey that the players on the bench are analogous to the ions in a crystal; and those on the court are analogous to the dissolved ions.

USE VISUALS Have students examine Figure 16.4. **Ask** In terms of polarity and bonds, why are oil and water insoluble in one another? *(For a nonpolar liquid, such as oil, to mix with water, hydrogen bonds must be broken and replaced by much weaker forces between water and the nonpolar compound.)*

Figure 16.2 Saturated Solution
In a saturated solution, a state of dynamic equilibrium exists between the solution and the excess solute. The rate of solvation (dissolving) equals the rate of crystallization, so the total amount of dissolved solute remains constant.
Predict *What would happen if you added more solute to this saturated solution?*

Solubility

How can you describe the equilibrium in a saturated solution?

If you add 36.0 g of sodium chloride to 100 g of water at 25°C, all of the 36.0 g of salt dissolves. But if you add one more gram of salt and stir, no matter how vigorously or for how long, only 0.2 g of the last portion will dissolve. Why does the remaining 0.8 g of salt remain undissolved? According to the kinetic theory, water molecules are in continuous motion. Therefore, they should continue to bombard the excess solid, solvating and removing the ions. As ions are solvated, they dissolve in the water. Based on this information, you might expect all of the sodium chloride to dissolve eventually. That does not happen, however, because an exchange process is occurring. New particles from the solid are solvated and enter into solution, as shown in Figure 16.2. At the same time, an equal number of already-dissolved particles crystallize. These particles come out of solution and are deposited as a solid. The mass of undissolved crystals remains constant.

What is happening in Figure 16.2? Particles move from the solid into the solution. Some dissolved particles move from the solution back to the solid. Because these two processes occur at the same rate, no net change occurs in the overall system. Such a solution is said to be saturated. A **saturated solution** contains the maximum amount of solute for a given quantity of solvent at a constant temperature and pressure. **In a saturated solution, a state of dynamic equilibrium exists between the solution and any undissolved solute, provided that the temperature remains constant.** At 25°C, 36.2 g of sodium chloride dissolved in 100 g of water forms a saturated solution. If additional solute is added to this solution, it will not dissolve.

The **solubility** of a substance is the amount of solute that dissolves in a given quantity of a solvent at a specified temperature and pressure to produce a saturated solution. Solubility is often expressed in grams of solute per 100 g of solvent (g/100 g H_2O). Sometimes the solubility of a gas is expressed in grams per liter of solution (g/L). A solution that contains less solute than a saturated solution at a given temperature and pressure is an **unsaturated solution.** If additional solute is added to an unsaturated solution, the solute will dissolve until the solution is saturated.

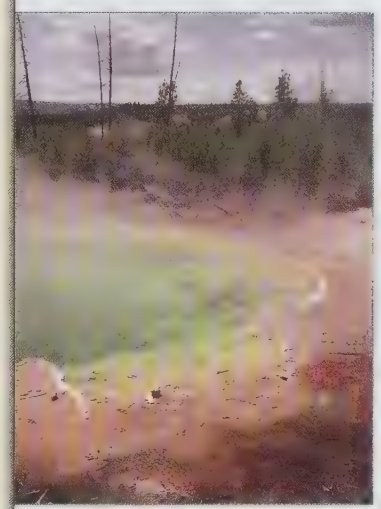


Figure 16.3 Hot Spring
The water in this hot spring in Yellowstone National Park is saturated with minerals. As the water cools near the edges of the spring, some of the minerals crystallize because they are less soluble at the lower temperature.

Check for Understanding

How can you describe the equilibrium in a saturated solution?

Have students create their own analogy to demonstrate their understanding of equilibrium in a saturated solution. Ask volunteers to share their analogies with the class.

ADJUST INSTRUCTION If students are having trouble answering, have them re-read the section on Solubility. Then re-state the basketball player substitution analogy, emphasizing the parts of the analogy most suited to clarifying any continuing misconceptions.

Some liquids—for example, water and ethanol—are infinitely soluble in each other. Any amount of ethanol will dissolve in a given volume of water, and vice versa. Similarly, ethylene glycol and water mix in all proportions. Pairs of liquids such as these are said to be completely miscible. Two liquids are **miscible** if they dissolve in each other in all proportions. In such a solution, the liquid that is present in the larger amount is usually considered the solvent. Liquids that are slightly soluble in each other—for example, water and diethyl ether—are partially miscible. Liquids that are insoluble in one another are **immiscible.** As you can see in Figure 16.4, oil and water are examples of immiscible liquids.

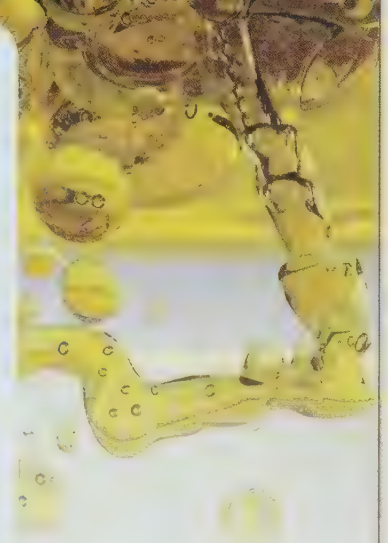

Figure 16.4 Oil and Water Vegetable oil is not soluble in water. Liquids that are insoluble in one another are immiscible.

Factors Affecting Solubility

What factors affect the solubility of a substance?

You have read that solubility is defined as the mass of solute that dissolves in a given mass of a solvent at a specified temperature. **Temperature affects the solubility of solid, liquid, and gaseous solutes in a solvent; both temperature and pressure affect the solubility of gaseous solutes.**

Temperature The solubility of most solid substances increases as the temperature of the solvent increases. For sodium chloride (NaCl), the increase in solubility is small—from 36.2 g per 100 g of water at 25°C to 39.2 g per 100 g of water at 100°C. Figure 16.5 shows how the solubility of several substances varies with temperature.

For a few substances, solubility decreases with temperature. For example, the solubility of ytterbium sulfate ($Yb_2(SO_4)_3$) in water drops from 44.2 g per 100 g of water at 0°C to 5.8 g per 100 g of water at 90°C. Table 16.1 on the next page lists the solubilities of some common substances in water at various temperatures.

InterpretGraphs

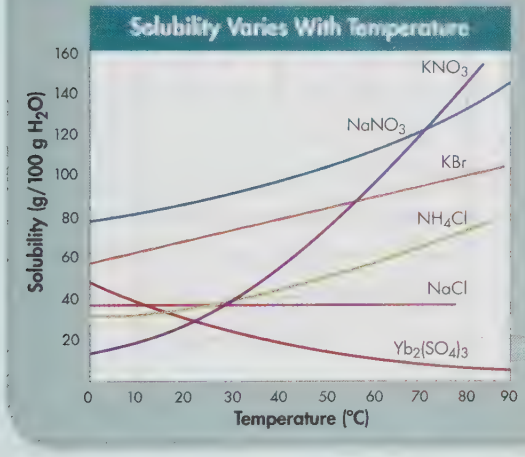

Figure 16.5 Changing the temperature usually affects the solubility of a substance.

a. Read Graphs What happens to the solubility of KNO_3 as the temperature increases?

b. Identify Which substance exhibits the least change in solubility as temperature increases?

c. Predict Suppose you added some solid NaCl to a saturated solution of NaCl at 20°C and warmed the mixture to 40°C. What would happen to the added NaCl?

d. Infer The mineral deposits around the hot spring in Figure 16.3 include NaCl and KCl. How do you think the solubility of KCl changes as the temperature decreases? Explain your answer.

Differentiated Instruction

L1 SPECIAL NEED STUDENTS Adapt demonstrations so that students who have difficulties in managing visual or auditory information can tactically experience the concepts involving solubility and saturated solutions. For example, fill a large bowl warm water and guide students agitate the water with one hand as you gradually add Epsom salts to the water. If students to describe what they feel at various points of the demonstration.

LPR LESS PROFICIENT READERS Have students draw and label a diagram illustrating the dynamic equilibrium of a saturated solution, with arrows describing the motion of particles between the crystalline and solvated states.

ELL ENGLISH LANGUAGE LEARNERS Convey that the word *miscible* comes from the Latin word *miscere*, meaning "to mix." Explain that the prefix *im–* means not. Point out that *immense* means "not capable of normal measurement" and *immobile* means "not capable of being moved." Help students to deduce that two liquids that are not soluble in each other are called *immiscible*.

Explain

Factors Affecting Solubility

INTERPRET DIAGRAMS Direct students' attention to Figure 16.5. Explain that the graph is used to show the way temperature affects six different ionic compounds. If students struggle to interpret the graph, consider showing the coordinate grid on an overhead with just the *x*- and *y*-labels and the title of the graph. Provide students with a table of data for each substance and, as a class, plot the data points in the table and then connect the points. Work with the data of only one substance at a time. Use interpolation and extrapolation techniques to make sure students understand how to interpret the graph. When the class is ready, direct them to answer the questions that correspond to Figure 16.5.

Extend

Direct students to review the compounds in Figure 16.5. **Ask** Predict the compounds you think have negative molar heats of solution. *(Answers will vary.)* Have students look up the ΔH_{soln} for each compound in the graph in a resource book such as *CRC Handbook of Chemistry and Physics*. **Ask** Summarize how the solubility curve for a compound is related to its ΔH_{soln}. *(Students should find that with the exception of $Yb_2(SO_4)_3$, for which data is not given, all of the compounds in the graph have positive ΔH_{soln} values at 25°C. Thus, heat is absorbed in the solution process for these compounds. Students may predict, then, that providing more heat by raising the temperature of a solution will increase solubility. Students may also note that NaCl, which shows the least increase in solubility with temperature, has the lowest positive ΔH_{soln} among the compounds discussed.)*

Answers

FIGURE 16.2 nothing

INTERPRETING GRAPHS

a. The solubility of KNO_3 increases as the temperature increases.

b. NaCl

c. Only a negligible amount of NaCl would go into solution, if any.

d. The solubility of KCl decreases as the temperature decreases. As the saturated hot spring water cools, it can no longer maintain the same concentration of KCl. As a result, some of the KCl crystallizes out of solution, forming the solid KCl deposits.

Explore

Factors Affecting Solubility

Teacher Demo

PURPOSE Students will observe the effects of pressure and agitation on the solubility of gases.

MATERIALS bottle of warm soda, bottle of chilled soda, 2 other bottles of soda

PROCEDURE Open a bottle of warm soda and a bottle of chilled soda. **Ask** What do you observe? *(Carbon dioxide gas comes out of solution much more quickly in the warm soda.)* Explain that the rush of bubbles in a warm bottle of soda can be a model for the "bends," a malady that afflicts divers when dissolved nitrogen forms bubbles in the bloodstream. Show students that the model also shows how the escape of carbon dioxide from rising magma can trigger a volcanic eruption. Point out that in each case, high pressure keeps a gas in solution; reduced pressure allows it to escape. Repeat the demonstration, this time using a shaken and unshaken bottle of soda. Have students compare and contrast the effect of agitation on the solubility of gases and solids.

SAFETY Be sure to open the shaken bottle in a sink or other partially enclosed area, to avoid spilling.

CHEMISTRY & YOU Crystal growing kits work by the evaporation of solvent (usually water) from a saturated or supersaturated solution. As the solvent evaporates, the solution can no longer contain the same amount of dissolved solute, and the solute gradually precipitates and forms solid crystals.

Table 16.1

Solubilities of Substances in Water at Various Temperatures

Substance		Solubility (g/100 g H_2O)

CHEMISTRY & YOU

Q: *How do you think crystal growing kits work? Use what you know about solubility and saturated solutions to explain your answer.*

Suppose you make a saturated solution of sodium ethanoate (sodium acetate) at 30°C and let the solution stand undisturbed as it cools to 25°C. Because the solubility of this compound is greater at 30°C than at 25°C, you expect that solid sodium ethanoate will crystallize from the solution as the temperature drops. But no crystals form. You have made a supersaturated solution. A **supersaturated solution** contains more solute than it can theoretically hold at a given temperature. The crystallization of a supersaturated solution can be initiated if a very small crystal, called a seed crystal, of the solute is added. The rate at which excess solute deposits upon the surface of a seed crystal can be very rapid, as shown in Figure 16.6. Crystallization can also occur if the inside of the container is scratched.

Another example of crystallization in a supersaturated solution is the production of rock candy. A solution is supersaturated with sugar. Seed crystals cause the sugar to crystallize out of solution onto a string for you to enjoy.

Professional Development Note

Fertilizer Runoff

Most farmers use fertilizers that contain salts of one or more of three elements essential to plant growth: potassium, nitrogen, and phosphorus. When more fertilizer is applied than the soil can absorb, rain washes off the excess salts. Not only is this economically wasteful, it is hazardous to the environment. The water containing these dissolved salts flows into streams and rivers, where the salts contribute to the eutrophication of the water. Eutrophied waters are rich in nutrients but deficient in dissolved oxygen due to excessive overgrowth of algae and oxygen-consuming bacteria. Signs of eutrophication include overgrowth of water plants, algal blooms, and bad odors resulting from the growth of bacteria that do not need oxygen. In recent years, the problem of fertilizer runoff has lessened with the introduction of slow-release nitrogenous fertilizers. Many farmers have also adopted new methods to reduce runoff.

522 Chapter 16 • Lesson 1

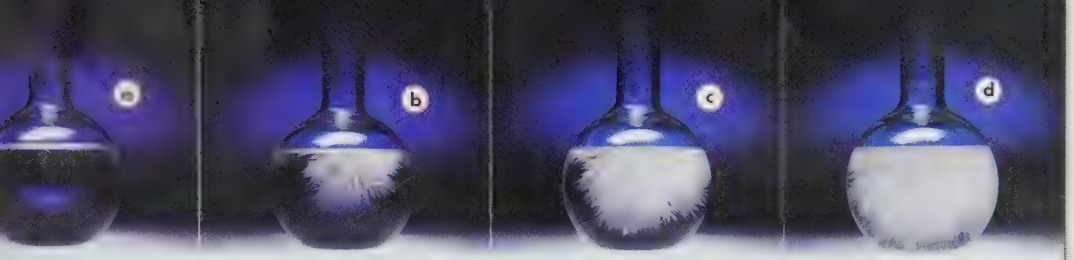

Figure 16.6 Supersaturated Solution
A supersaturated solution of sodium ethanoate ($NaC_2H_3O_2(aq)$) crystallizes rapidly when disturbed.
a. The solution is clear before a seed crystal is added. **b.** Crystals begin to form in the solution immediately after the addition of a seed crystal. **c–d.** The excess solute crystallizes rapidly.
Infer *When the crystallization has ceased, will the solution be saturated or unsaturated?*

The effect of temperature on the solubility of gases in liquid solvents is opposite that of solids. The solubilities of most gases are greater in cold water than in hot. For example, Table 16.1 shows that the most important component of air for living beings—oxygen—becomes less soluble in water as the temperature of the solution rises. This fact has some important consequences. When an industrial plant takes water from a lake to use for cooling and then dumps the resulting heated water back into the lake, the temperature of the entire lake increases. Such a change in temperature is known as thermal pollution. Aquatic animal and plant life can be severely affected because the increase in temperature lowers the concentration of dissolved oxygen in the lake water.

Pressure Changes in pressure have little effect on the solubility of solids and liquids, but pressure strongly influences the solubility of gases. Gas solubility increases as the partial pressure of the gas above the solution increases. Carbonated beverages are a good example. These drinks contain large amounts of carbon dioxide (CO_2) dissolved in water. Dissolved CO_2 makes the liquid fizz and your mouth tingle. The drinks are bottled under a high pressure of CO_2 gas, which forces large amounts of the gas into solution. When a carbonated-beverage container is opened, the partial pressure of CO_2 above the liquid decreases. Immediately, bubbles of CO_2 form in the liquid and escape from the open bottle, as shown in Figure 16.7. As a result, the concentration of dissolved CO_2 decreases. If the bottle is left open, the drink becomes "flat" as the solution loses most of its CO_2.

How is the partial pressure of carbon dioxide gas related to the solubility of CO_2 in a carbonated beverage? The relationship is described by **Henry's law,** which states that at a given temperature, the solubility (S) of a gas in a liquid is directly proportional to the pressure (P) of the gas above the liquid. In other words, as the pressure of the gas above the liquid increases, the solubility of the gas increases. Similarly, as the pressure of the gas decreases, the solubility of the gas decreases. You can write the relationship in the form of an equation.

S_1 is the solubility of a gas at one pressure, P_1; S_2 is the solubility at another pressure, P_2.

Figure 16.7 CO_2 in Solution
When a carbonated-beverage bottle is sealed, the pressure of CO_2 above the liquid is high, and the concentration of CO_2 in the liquid is also high. When the cap is removed, the pressure of CO_2 gas above the liquid decreases, and carbon dioxide bubbles out of the liquid.

Foundations for Math

PROPORTIONAL RELATIONSHIPS Explain that Henry's law is a proportion since it expresses two ratios that are equal. To find an unknown value in a proportion, students can use cross products and inverse operations.

In **Sample Problem 16.1,** cross products and inverse operations are used to isolate S_2 in order to identify the solubility of the gas at 1.0 atm.

$\frac{S_1}{P_1} = \frac{S_2}{P_2}$ Start with Henry's Law equaton.

$S_1P_2 = S_2P_1$ Use cross products.

$\frac{S_1P_2}{P_1} = S_2$ Use the inverse property of multiplication.

Point out that any variable in Henry's Law can be determined using the same method.

Explain

USE AN ANALOGY Explain that the action of a gas pressing down on the surface of a liquid, thus increasing the solubility of the gas in the liquid, is like the action of a hammer driving a nail into a piece of wood. Explain or demonstrate that the harder a nail is hit, the farther the nail is driven into the wood. Convey that the hammer is analogous to pressure, the nail to solute gas, and the wood to solvent liquid.

Answers

FIGURE 16.6 saturated

Explain

Sample Practice Problem

The solubility of a gas is 1.04 g/L at 98.0 kPa and 25°C. What is the solubility of the same gas at 125 kPa and 25°C? *(1.33 g/L)*

Extend

Connect to GEOLOGY

Explain that caves form as the result of different processes, one of which is solution formation. Solutional caves form from limestone and gypsum. Encourage students to research the processes by which solutional caves, such as the Carlsbad Caverns, form. Ask students to share the results of their research with the class.

Evaluate

Informal Assessment

Assess students' understanding of the properties of solutions by writing the following words on the board: agitation, temperature, and particle size. **Ask** Which of these factors affects the solubility of a substance? *(temperature only)* **Ask** How is the solubility of a gas affected by the pressure of the gas above the liquid? *(The solubility of the gas increases with increasing pressure.)* Then have students complete the 16.1 Lesson Check.

Reteach

For students who struggle with the assessment, review the factors that affect the aqueous solubilities of solid and gaseous substances—temperature and pressure. Make sure that students are able to distinguish between the factors that affect the solubility and those that affect the rate of solution, such as agitation and particle size. Tell students that solubility is the amount of a substance that will dissolve in a given amount of solvent, whereas rate of solution is the amount of solute entering a solution per unit time. Convey that temperature is the only factor discussed that affects both the rate of solution and the solubility.

Sample Problem 16.1

Using Henry's Law

If the solubility of a gas in water is 0.77 g/L at 3.5 atm of pressure, what is its solubility (in g/L) at 1.0 atm of pressure? (The temperature is held constant at 25°C.)

1 Analyze **List the knowns and the unknown.** Use Henry's law to solve for the unknown solubility.

2 Calculate **Solve for the unknown.**

KNOWNS	UNKNOWN
$P_1 = 3.5$ atm	$S_2 = ?$ g/L
$S_1 = 0.77$ g/L	
$P_2 = 1.0$ atm	

How do you rearrange the Henry's law equation?

$$\frac{S_1}{P_1} = \frac{S_2}{P_2}$$

Isolate S_2 by multiplying both sides by P_2:

$$P_2 \times \frac{S_1}{P_1} = \frac{S_2}{P_2} \times P_2$$

Solve Henry's law for S_2. Substitute known values and calculate.

$$S_2 = \frac{S_1 \times P_2}{P_1} = \frac{0.77 \text{ g/L} \times 1.0 \cancel{\text{atm}}}{3.5 \cancel{\text{atm}}} = 0.22 \text{ g/L}$$

3 Evaluate **Does the result make sense?** The new pressure is approximately one third of the original pressure, so the new solubility should be approximately one third of the original. The answer is correctly expressed to two significant figures.

In Problem 1, you're solving Henry's law for an unknown solubility. In Problem 2, you're solving for an unknown pressure.

1. The solubility of a gas in water is 0.16 g/L at 104 kPa. What is the solubility when the pressure of the gas is increased to 288 kPa? Assume the temperature remains constant.

2. A gas has a solubility in water at 0°C of 3.6 g/L at a pressure of 1.0 atm. What pressure is needed to produce an aqueous solution containing 9.5 g/L of the same gas at 0°C?

16.1 LessonCheck

3. Review What determines how fast a substance will dissolve?

4. Describe How can you describe the state of equilibrium in a saturated solution that contains undissolved solute?

5. Describe What condition(s) determine the solubilities of solid, liquid, and gaseous solutes in a solvent?

6. Identify Name a unit used to express solubility.

7. Describe What determines whether or not a substance will dissolve?

8. Explain What would you do to change
- **a.** a saturated solid/liquid solution to an unsaturated solution?
- **b.** a saturated gas/liquid solution to an unsaturated solution?

9. Calculate The solubility of a gas is 0.58 g/L at a pressure of 104 kPa. What is its solubility if the pressure increases to 250 kPa at the same temperature?

Lesson Check Answers

3. agitation, temperature, particle size of the solute

4. A dynamic equilibrium exists between the solution and the undissolved solute, provided that the temperature remains constant. As new particles from the solid are solvated and enter into solution, an equal number of already-dissolved particles crystallize.

5. temperature (if the solute is a solid or liquid); temperature and pressure (if the solute is a gas)

6. grams of solute per 100 g of solvent

7. chemical composition of the solute and solvent

8. **a.** Add solvent.
b. Increase the pressure.

9. 1.4 g/L

16.2 Concentrations of Solutions

C.7.1 Composition and properties of solutions; C.7.4 Prepare a solution

CHEMISTRY & YOU

Q: *How can you describe the concentration of a solution?* Clean drinking water is important for all communities. What constitutes clean water? Your federal and state governments set standards limiting the amount of contaminants allowed in drinking water. These contaminants include metals, pesticides, and bacteria. Water must be tested continually to ensure that the concentrations of these contaminants do not exceed established limits.

Key Questions

- *How do you calculate the molarity of a solution?*
- *What effect does dilution have on the amount of solute?*
- *How do percent by volume and percent by mass differ?*

Vocabulary

- concentration
- dilute solution
- concentrated solution
- molarity (*M*)

Molarity

How do you calculate the molarity of a solution?

You have learned that a substance can dissolve to some extent in a particular solvent to form a solution. This lesson focuses on ways to express the actual extent of dissolving. The **concentration** of a solution is a measure of the amount of solute that is dissolved in a given quantity of solvent. A solution that contains a relatively small amount of solute is a **dilute solution.** By contrast, a **concentrated solution** contains a large amount of solute. An aqueous solution of sodium chloride containing 1 g NaCl per 100 g H_2O might be described as dilute when compared with a sodium chloride solution containing 30 g NaCl per 100 g H_2O. But the same solution might be described as concentrated when compared with a solution containing only 0.01 g NaCl per 100 g H_2O. You can see that the terms *concentrated* and *dilute* are only qualitative descriptions of the amount of a solute in solution.

How can concentration be expressed quantitatively? In chemistry, the most important unit of concentration is molarity. **Molarity (*M*)** is the number of moles of solute dissolved in one liter of solution. Molarity is also known as molar concentration. When the symbol *M* is accompanied by a numerical value, it is read as "molar." Figure 16.8 illustrates the procedure for making a 0.5*M*, or 0.5-molar, solution. Note that the volume involved is the total volume of the resulting solution, not the volume of the solvent alone.

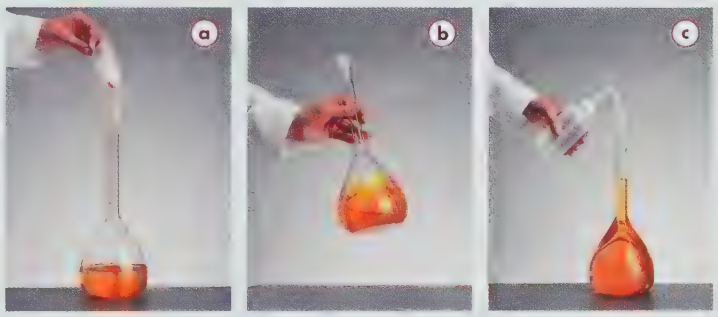

Figure 16.8 How to Make a 0.5*M* Solution
a. Add 0.5 mol of solute to a 1-L volumetric flask that is half filled with distilled water. **b.** Swirl the flask carefully to dissolve the solute. **c.** Fill the flask with water exactly to the 1-L mark.

Key Objectives

16.2.1 CALCULATE the molarity of a solution.

16.2.2 DESCRIBE the effect of dilution on the total moles of solute in solution.

16.2.3 EXPRESS solution concentration as a percent by volume or percent by mass.

Engage

CHEMISTRY & YOU Have students study the photograph and read the text. **Ask** What substances may be contaminants in drinking water? *(metals, pesticides, bacteria, water treatment by-products)* **Ask** How is the quality of drinking water assessed? *(Federal and state governments set standards that limit the concentration of contaminants allowed in drinking water.)*

Activate Prior Knowledge

Review the concepts of chemical quantities that were introduced in Chapter 10. **Ask** How many moles are in 12.0 g of NaCl? *(0.205 mol)* **Ask** How many grams are in 1.50 mol of NaOH? *(60.0 g)* **Ask** Which contains more molecules: 1.00 mol SO_2 or 1.00 mol SO_3? *(Numbers are equal.)* Which contains more mass? *(1.00 mol SO_3)*

IN ACADEMIC STANDARDS for SCIENCE

C.7.1 Describe the composition and properties of types of solutions.

C.7.4 Prepare a specific volume of a solution of a given molarity when provided with a known solute.

Focus on ELL

1 CONTENT AND LANGUAGE Prepare students for the mathematics in this lesson by helping them to create a useful reference sheet. Have students preview the lesson and create a listing of key words and their corresponding math symbols. Tell students to also include on their sheet the units of measure and their corresponding chemical quantity.

2 FRONTLOAD THE LESSON Ask students to share their experiences with canned soup. Point out that soups which have the term *condensed* on their labels require the addition of more liquid before consumption. When they add water or another liquid to a condensed soup, they are making a dilution. Tell students to keep this in mind as they read the lesson.

3 COMPREHENSIBLE INPUT Walk students through Sample Problems 16.2 and 16. 4. Then, physically demonstrate the processes of making the solutions that result from the calculations as a visual support for the concepts of molarity and dilution.

Answers

1. $S_2 = (S_1 \times P_2)/P_1 = (0.16\ g/L \times 288\ kPa)/104\ kPa = 4.4 \times 10^{-1}\ g/L$
2. $P_2 = (P_1 \times S_2)/S_1 = (1.0\ atm \times 9.5\ g/L)/3.6\ g/L = 2.6\ atm$

Foundations for Reading

BUILD VOCABULARY Have students make a web diagram showing how *dilute solution, concentrated solution,* and *molarity* are related to *concentration*.

READING STRATEGY Have students identify the main ideas of this section by listing the key concepts under each heading.

Explain

Molarity

USE VISUALS Direct students' attention to Figure 16.8 on page 525. Students may think that solutions of given molarity can be correctly prepared by addition of the solute to a premeasured volume of solvent. They often forget that the solute will take up some of the available space in the volumetric flask. Explain that the sequence of steps is important when making up standard solutions because the solute plus the solvent may take up more volume than the solvent alone. **Ask** Why is it important that the solute be added to some of the solvent and dissolved, and then solvent be added up to the 1 L mark on the volumetric flask? *(The total volume of the mixture is likely to exceed the desired volume if the solute is directly added to a full liter of solvent.)*

Sample Practice Problem

A solution of KCl contains 34.75 g of solute in 250 mL of solution. Determine the molarity of the solution. *(1.86M KCl)*

Extend

Connect to MEDICINE

Tell students that a patient in a hospital is often administered an intravenous (IV) drip containing an aqueous solution. The patient may need the solution to prevent dehydration or to administer nutrients or medicines. Explain that great care must be taken when fluids are introduced into the bloodstream in order to keep the balance of dissolved electrolytes inside and outside of the tissue cells from being altered. Have students research the effects of an electrolyte imbalance on humans as a result of dehydration.

To calculate the molarity of a solution, divide the number of moles of solute by the volume of the solution in liters.

$$\text{Molarity } (M) = \frac{\text{moles of solute}}{\text{liters of solution}}$$

For example, suppose 2 mol of glucose are dissolved in 5 L of solution. You would calculate the molarity of the solution as follows:

$$\frac{2 \text{ mol glucose}}{5 \text{ L solution}} = 0.4 \text{ mol/L} = 0.4M$$

If the amount of solute in a solution is expressed in mass units instead of moles, you can calculate molarity by using the appropriate conversion factors, as shown in Sample Problem 16.2.

Sample Problem 16.2

Calculating Molarity

Intravenous (IV) saline solutions are often administered to patients in the hospital. One saline solution contains 0.90 g NaCl in exactly 100 mL of solution. What is the molarity of the solution?

KNOWNS
solution concentration = 0.90 g NaCl/100 mL
molar mass of NaCl = 58.5 g/mol

UNKNOWN
solution concentration = ?M

1 Analyze **List the knowns and the unknown.**
Convert the concentration from g/100 mL to mol/L. The sequence is g/100 mL ⟶ mol/100 mL ⟶ mol/L.

2 Calculate **Solve for the unknown.**

Use the molar mass to convert g NaCl/100 mL to mol NaCl/100 mL. Then convert the volume units so that your answer is expressed in mol/L.

$$\text{Solution Concentration} = \frac{0.90 \text{ g NaCl}}{100 \text{ mL}} \times \frac{1 \text{ mol NaCl}}{58.5 \text{ g NaCl}} \times \frac{1000 \text{ mL}}{1 \text{ L}}$$

$$= 0.15 \text{ mol/L}$$

$$= 0.15M$$

The relationship 1 L = 1000 mL gives you the conversion factor 1000 mL/1 L.

3 Evaluate **Does the result make sense?** The answer should be less than 1*M* because a concentration of 0.90 g/100 mL is the same as 9.0 g/1000 mL (9.0 g/1 L), and 9.0 g is less than 1 mol of NaCl. The answer is correctly expressed to two significant figures.

10. A solution has a volume of 2.0 L and contains 36.0 g of glucose ($C_6H_{12}O_6$). If the molar mass of glucose is 180 g/mol, what is the molarity of the solution?

11. A solution has a volume of 250 mL and contains 0.70 mol NaCl. What is its molarity?

Foundations for Math

CONVERSION FACTORS Tell students if they identify the unit of measure of the desired answer first, they can work backwards to determine which conversion factors are needed in the entire problem. Show students a simple example converting days to seconds. Point out that this same strategy can be used to organize molarity calculations.

In **Sample Problem 16.2,** the desired units are mol/L, but the starting units are mass (in grams) and volume in mL. Point out that to arrive at an answer in moles per liter, students will need two conversion factors: one for converting grams to moles and another that converts milliliters to liters.

In some cases, you may need to determine the number of moles of solute dissolved in a given volume of solution. You can do this if the molarity of the solution is known. For example, how many moles are in 2.00 L of 2.5*M* lithium chloride (LiCl)? First, rearrange the formula for molarity to solve for the number of moles. Then, substitute the known values for molarity and volume.

$$\text{Molarity } (M) = \frac{\text{moles of solute}}{\text{liters of solution } (V)}$$

$$\text{Moles of solute} = \text{molarity } (M) \times \text{liters of solution } (V)$$

$$= 2.5M \times 2.00\ \text{L} = \left(\frac{2.5\ \text{mol}}{1\ \text{L}}\right) \times 2.00\ \text{L}$$

$$= 5.0\ \text{mol}$$

Thus, 2.00 L of 2.5*M* lithium chloride solution contains 5.0 mol of LiCl.

Sample Problem 16.3

Calculating the Moles of Solute in a Solution

Household laundry bleach is a dilute aqueous solution of sodium hypochlorite (NaClO). How many moles of solute are present in 1.5 L of 0.70*M* NaClO?

1 Analyze **List the knowns and the unknown.** The conversion is volume of solution ⟶ moles of solute. Molarity has the units mol/L, so you can use it as a conversion factor between moles of solute and volume of solution.

KNOWNS
volume of solution = 1.5 L
solution concentration = 0.70*M* NaClO

UNKNOWN
moles solute = ? mol

2 Calculate **Solve for the unknown.**

Multiply the given volume by the molarity expressed in mol/L.

$$1.5\ \text{L} \times \frac{0.70\ \text{mol NaClO}}{1\ \text{L}} = 1.1\ \text{mol NaClO}$$

3 Evaluate **Does the result make sense?** The answer should be greater than 1 mol but less than 1.5 mol, because the solution concentration is less than 0.75 mol/L and the volume is less than 2 L. The answer is correctly expressed to two significant figures.

12. How many moles of ammonium nitrate are in 335 mL of 0.425*M* NH_4NO_3?

13. How many moles of solute are in 250 mL of 2.0*M* $CaCl_2$? How many grams of $CaCl_2$ is this?

Make sure that your volume units cancel when you do these problems. If they don't, then you're probably missing a conversion factor in your calculations.

Foundations for Math

UNITS OF MEASUREMENT As discussed in Sample Problem 16.2, an important step in making calculations of chemical quantities is identifying the necessary conversion factors. Another useful step is writing a skeleton equation. This allows students the opportunity to test their choice of conversion factors to insure the proper units once the problem is solved.

For **Sample Problem 16.3**, the following skeleton equation can be written to make sure that the final units of measurement will be correct:

$$\text{L} \times \frac{\text{mol}}{\text{L}} = \text{mol}$$

Because the desired units is the number of moles, the conversion factor is correct and the problem can be solved once the proper quantities are added to the units.

Explore

Class Activity

PURPOSE Students will learn how to prepare molar solutions.

MATERIALS water; NaCl; sucrose; 50-mL, 100-mL, and 1-L volumetric flasks; balance; graph paper

PROCEDURE Have students determine the mass of a 50-mL, 100-mL, and a 1-L volumetric flask. Review the definition of 1 *M* and how to calculate the mass of 1 mol of NaCl (58.5 g). Add 500 mL of water to the 1-L volumetric flask and add 1 mol of NaCl. Swirl the flask until the NaCl dissolves. Add water up to the 1-L mark.

Ask Does the flask contain a liter of water? *(No, because the dissolved NaCl takes up some volume.)* Have students prepare 0.0625*M*, 0.125*M*, 0.250*M*, and 0.500*M* solutions of sucrose using the 100-mL and 50-mL volumetric flasks. **Ask** What is the mass of each solution? **Ask** What is the density of each solution? *(Density = (mass of flask + solution – mass of flask)/mL of solution.)* Have students make a graph of density versus concentration; include the density of pure water (1 g/mL).

EXPECTED OUTCOME The graph shows that density is directly proportional to concentration.

Sample Practice Problem

How many grams of solute are in 2.40 L of 0.650*M* $HClO_2$? *(107 g)*

Answers

10. (36.0 g/2.0 L solution) × (1 mol/180 g) = $1.0 \times 10^{-1}M$

11. (0.70 mol/250 mL) × (1000 mL/ 1 L) = 2.8*M*

12. 335 mL × (1L/1000 mL) × (0.425 mol/1L) = 1.42×10^{-1} mol NH_4NO_3

13. 250 mL × (1L/1000 mL) × 2.0 mol/L = 5.0×10^{-1} mol $CaCl_2$; 5.6×10^{1} g $CaCl_2$

Explain

Making Dilutions

APPLY CONCEPTS Remind students that when substances react, they do so as particles and that moles of different substances contain the same number of representative particles. Because many reactions occur in solution, a unit of concentration based on moles, such as molarity, is needed to provide information about the number of reactant particles in solution.

USE VISUALS Have students examine Figure 16.10. Remind students that when making dilute solutions, the accuracy of the resulting solution's concentration is dependent upon the measuring devices used. Show students that using a graduated cylinder to measure is much less accurate than using a volumetric pipette or buret.

Explore

Class Activity

PURPOSE Students practice calculating the variables in the definition of molarity.

MATERIALS calculator, paper, pencil

PROCEDURE Divide students into groups of three. One student should name a solute; the other two should each specify one of three quantities: *solute mass, solution volume,* or *molarity.* The unspecified quantity should then be calculated with input from each member. For example, the first student may say "sodium chloride," the second may say "12 grams," and the third may say "2.5 liters." The group would then have to calculate the molarity of the resulting solution. Each group should carry out at least one calculation involving each of the possible unknown quantities.

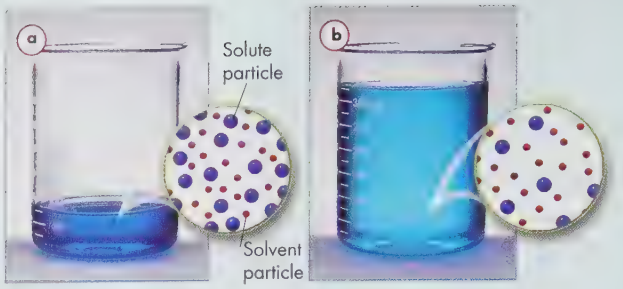

Figure 16.9 Dilution
Adding solvent to a concentrated solution lowers the concentration, but the total number of moles of solute present remains the same.

Making Dilutions

What effect does dilution have on the amount of solute?

Both of the solutions in Figure 16.9 contain the same amount of solute. You can tell by the color of solution (a) that it is more concentrated than the solution (b); that is, solution (a) has the greater molarity. The more dilute solution (b) was made from solution (a) by adding more solvent. **Diluting a solution reduces the number of moles of solute per unit volume, but the total number of moles of solute in solution does not change.** You can also express this concept by writing an equation.

$$\text{Moles of solute before dilution} = \text{moles of solute after dilution}$$

Now recall the definition of molarity and how it can be rearranged to solve for moles of solute.

$$\text{Molarity } (M) = \frac{\text{moles of solute}}{\text{liters of solution } (V)}$$

$$\text{Moles of solute} = \text{molarity } (M) \times \text{liters of solution } (V)$$

The total number of moles of solute remains unchanged upon dilution, so you can now write this equation:

$$\text{Moles of solute} = M_1 \times V_1 = M_2 \times V_2$$

M_1 and V_1 are the molarity and volume of the initial solution, and M_2 and V_2 are the molarity and volume of the diluted solution. Volumes can be in liters or milliliters, as long as the same units are used for both V_1 and V_2. Figure 16.10 illustrates the procedure used for making a dilution in the lab.

Figure 16.10 Making a Dilution
The student is preparing 100 mL of 0.40*M* $MgSO_4$ from a stock solution of 2.0*M* $MgSO_4$. **a.** She measures 20 mL of the stock solution with a 20-mL pipette. **b.** She transfers the 20 mL to a 100-mL volumetric flask. **c.** She carefully adds water to the mark to make 100 mL of solution.
Compare ***How many moles of $MgSO_4$ are in 20 mL of the stock solution? In 100 mL of the dilute solution?***

UbD Check for Understanding

What effect does dilution have on the amount of solute?

Assess students' understanding of dilution by asking them to complete the following cloze prompt:

When a dilution is made, the _____ decreases, but the _____ remains the same. *(molarity; moles of solute or amount of solute)*

ADJUST INSTRUCTION If students are having difficulty answering the question, have them review third equation shown in the text: moles of solute = molarity (M) × liters of solution (V). Remind students that for moles of solute to remain the same, molarity must decrease if volume increases.

Sample Problem 16.4

Preparing a Dilute Solution

How many milliliters of aqueous 2.00*M* $MgSO_4$ solution must be diluted with water to prepare 100.0 mL of aqueous 0.400*M* $MgSO_4$?

KNOWNS

M_1 = 2.00*M* $MgSO_4$
M_2 = 0.400*M* $MgSO_4$
V_2 = 100.0mL of 0.400*M* $MgSO_4$

UNKNOWN

V_1 = ? mL of 2.00*M* $MgSO_4$

1 Analyze **List the knowns and the unknown.** Use the equation $M_1 \times V_1 = M_2 \times V_2$ to solve for the unknown initial volume of solution (V_1) that is diluted with water.

2 Calculate **Solve for the unknown.**

Solve for V_1 and substitute the known values into the equation.

$$V_1 = \frac{M_2 \times V_2}{M_1} = \frac{0.400\cancel{M} \times 100.0\ \text{mL}}{2.00\cancel{M}} = 20.0\ \text{mL}$$

Thus 20.0 mL of the initial solution must be diluted by adding enough water to increase the volume to 100.0 mL.

3 Evaluate **Does the result make sense?** The initial concentration is five times larger than the dilute concentration. Because the number of moles of solute does not change, the initial volume of solution should be one fifth the final volume of the diluted solution.

14. How many milliliters of a solution of 4.00*M* KI are needed to prepare 250.0 mL of 0.760*M* KI?

15. How could you prepare 250 mL of 0.20*M* NaCl using only a solution of 1.0*M* NaCl and water?

What kind of volume-measuring device would you use to make the dilution in Sample Problem 16.4? The dilution requires a molarity with three significant figures, so you would need to measure 20.0 mL of the 2.00*M* $MgSO_4$ solution with a 20-mL volumetric pipette or a burette. (A graduated cylinder would not provide enough precision.) You would transfer the solution to a 100-mL volumetric flask and add distilled water to the flask exactly up to the etched line. The contents would then be 100.0 mL of 0.400*M* $MgSO_4$.

Percent Solutions

How do percent by volume and percent by mass differ?

If both the solute and the solvent are liquids, a convenient way to make a solution is to measure the volumes of the solute and the solution. The concentration of the solute is then expressed as a percent of the solution by volume.

Percent by volume of a solution is the ratio of the volume of solute to the volume of solution. For example, isopropyl alcohol (2-propanol) is sold as a 91 percent solution by volume. You could prepare such a solution by diluting 91 mL of pure isopropyl alcohol with enough water to make 100 mL of solution. The concentration is written as 91 percent by volume, 91 percent (volume/volume), or 91% (v/v).

$$\text{Percent by volume (\%(v/v))} = \frac{\text{volume of solute}}{\text{volume of solution}} \times 100\%$$

Foundations for Math

SUBSTITUTION If students are not comfortable manipulating a literal formula for a desired variable, explain that they can arrive at the same solution if they substitute given values first and then solve for the unknown.

Solve **Sample Problem 16.4** by first substituting the given values into the formula. Then use inverse operations to solve for the unknown volume.

$$M_1 \times V_1 = M_2 \times V_2$$

$$2.00M\ MgSO_4 \times V_1 = 0.400M\ MgSO_4 \times 100.0\ \text{mL}$$

$$\frac{\cancel{2.00M\ MgSO_4} \times V_1}{\cancel{2.00M\ MgSO_4}} = \frac{0.400\cancel{M\ MgSO_4} \times 100.0\ \text{mL}}{2.00\cancel{M\ MgSO_4}}$$

$$V_1 = \frac{0.400 \times 100.0\ \text{mL}}{2.0} = 20.0\ \text{mL}$$

Explain

Dilutions

MAKE A CONNECTION If students are having difficulty with the concepts of molarity and dilution, have them consider diluting a container of juice concentrate (frozen or liquid). Convey that no matter how much water is added to the concentrate, the initial quantity of concentrate does not change. Explain that what changes is the amount of concentrate in a given volume of the diluted solution. Have students consider using only a fraction of the original concentrate. For example, a gallon of juice prepared from half a can will contain half as much concentrate as a gallon prepared from the entire can. Students should be able to deduce that, in this case, the molarity would be reduced by one-half.

USE MODELS Have students work in groups of three to explore dilution. Have each group bring in a shoe box and put 20 red beads into it. Tell students that these red beads represent solute molecules. Then have students add 40 green beads to the box. Tell students that these beads represent solvent molecules. Students should see that the box contains twice as many green beads as red beads; thus, the concentration is 0.5 red/green. Now add another 40 green beads. Explain that this model is analogous to a dilution from 0.5 to 0.25 red/green. Point out that although the concentration of red beads has been halved, the total number of red beads has not changed. Show students that if each red bead represents a mole of solute, 20 moles of solute would still be in solution.

Sample Practice Problem

How many milliliters of a 6.00*M* stock solution of $NH_3(aq)$ would you need to prepare 100.0 mL of 0.30*M* $NH_3(aq)$? *(5.0 mL)*

Answers

FIGURE 16.10 0.040 mol $MgSO_4$(both before and after the dilution)

14. $V_1 = (M_2 \times V_2)/M_1 = (0.760M \times 250.0\ \text{mL})/4.00M = 4.75 \times 10^1$ mL

15. Use a volumetric pipette to transfer 5.0×10^1 mL of the 1.0*M* solution to a 250-ml volumetric flask. Then add distilled water up to the mark.

LESSON 16.2

Explain

Percent Solutions

MAKE A CONNECTION Display various fruit-flavored drinks. **Ask** What method is used to determine the percent of juice in the drink, percent by volume, or percent by mass? *(Answers will vary.)* Have students consider whether one or the other method might present the product in a more favorable light. **Ask** Do you think the name "fruit drink" is misleading to consumers? *(Answers will vary.)*

Sample Practice Problem

Ethanol is mixed with gasoline to make gasohol. What is the percent by volume of ethanol in gasohol when 95 mL of ethanol is added to sufficient gasoline to make 1.0 L of gasohol? *(9.5% (v/v))*

CHEMISTRY & YOU Molarity = moles of solute/liters of solution; percent by volume = volume of solute/volume of solution × 100%; percent by mass = mass of solute/mass of solution × 100%

Explore

Teacher Demo

PURPOSE Students will learn how to prepare standard solutions efficiently.

MATERIALS four 20-mL test tubes, 10 mL of 0.5*M* surcose, 15 mL water, 10-mL pipet

PROCEDURE Remind students of the activity in which they prepared molar solutions of sucrose. Convey that each solution was prepared independently. **Ask** Is there a more efficient way to prepare this same set of molar solutions? *(Yes; make serial dilutions.)* Place 10 mL of 0.5*M* sucrose in one test tube and 5 mL water in each of three others. Using a 10-mL pipette, transfer 5 mL of the 0.5*M* solution to the second test tube; mix by pipeting up and down. Repeat this process for the third and fourth test tubes. Have students calculate the molarities of each of the resulting solutions. Tell students that serial dilutions are used to prepare extremely dilute solutions, such as 0.000001*M* sucrose. The procedure eliminates the error that would arise from having to measure out very small volumes of stock solutions.

Sample Problem 16.5

Calculating Percent by Volume

What is the percent by volume of ethanol (C_2H_6O, or ethyl alcohol) in the final solution when 85 mL of ethanol is diluted to a volume of 250 mL with water?

KNOWNS
volume of solute = 85 mL ethanol
volume of solution = 250 mL

UNKNOWN
Percent by volume = ? % ethanol (v/v)

1 Analyze **List the knowns and the unknown.** Use the known values for the volume of solute and volume of solution to calculate percent by volume.

2 Calculate **Solve for the unknown.**

State the equation for percent by volume.

$$\text{Percent by volume (\% (v/v))} = \frac{\text{volume of solute}}{\text{volume of solution}} \times 100\%$$

Substitute the known values into the equation and solve.

$$\%\,(v/v) = \frac{85\ \text{mL ethanol}}{250\ \text{mL}} \times 100\%$$

$$= 34\%\ \text{ethanol (v/v)}$$

3 Evaluate **Does the result make sense?** The volume of the solute is about one third the volume of the solution, so the answer is reasonable. The answer is correctly expressed to two significant figures.

16. If 10 mL of propanone (C_3H_6O, or acetone) is diluted with water to a total solution volume of 200 mL, what is the percent by volume of propanone in the solution?

17. A bottle of the antiseptic hydrogen peroxide (H_2O_2) is labeled 3.0% (v/v). How many mL H_2O_2 are in a 400.0-mL bottle of this solution?

Another way to express the concentration of a solution is as a percent by mass, or percent (mass/mass). **Percent by mass of a solution is the ratio of the mass of the solute to the mass of the solution.**

$$\text{Percent by mass (\%(m/m))} = \frac{\text{mass of solute}}{\text{mass of solution}} \times 100\%$$

CHEMISTRY & YOU

Q: *What are three ways to calculate the concentration of a solution?*

You can also define percent by mass as the number of grams of solute per 100 g of solution. Percent by mass is sometimes a convenient measure of concentration when the solute is a solid. For example, a solution containing 7 g of sodium chloride in 100 grams of solution has a concentration of 7 percent by mass—also written as 7 percent (mass/mass) or 7% (m/m).

You have probably seen information on food labels expressed as a percent composition. For example, the label on a fruit-flavored drink often indicates the "percent juice" contained in the product. Such information can be misleading unless the units are given. When you describe percent solutions, be sure to specify whether the concentration is % (v/v) or % (m/m).

Differentiated Instruction

L1 **STRUGGLING STUDENTS** Write the dilution equation on the board: $M_1 \times V_1 = M_2 \times V_2$. Show students that when mol/*V* is substituted for *M*, the volumes cancel out, leaving moles. Emphasize that, when diluting a solution, the initial number of moles is the same as the final number of moles. Work through several examples using the dilution equation.

ELL **ENGLISH LANGUAGE LEARNERS** Restate the steps for solving the sample problems in simplified language. Use drawings when possible to promote comprehension by beginning and intermediate speakers. Allow more advanced speakers to translate the sample problems into their native language for their classmates when appropriate.

SampleProblem 16.6

Using Percent by Mass as a Conversion Factor

How many grams of glucose ($C_6H_{12}O_6$) are needed to make 2000 g of a 2.8% glucose (m/m) solution?

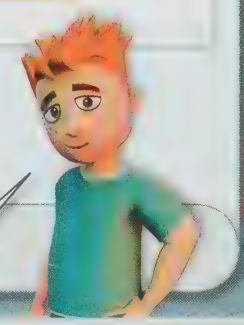
1 Analyze **List the knowns and the unknown.** The conversion is mass of solution ⟶ mass of solute. In a 2.8% $C_6H_{12}O_6$ (m/m) solution, each 100 g of solution contains 2.8 g of glucose. Used as a conversion factor, the concentration allows you to convert g of solution to g of $C_6H_{12}O_6$.

KNOWNS
mass of solution = 2000 g
percent by mass = 2.8% $C_6H_{12}O_6$ (m/m)

UNKNOWN
mass of solute = ? g $C_6H_{12}O_6$

2 Calculate **Solve for the unknown.**

Write the percent by mass as a conversion factor with g $C_6H_{12}O_6$ in the numerator.



$$\frac{2.8\ g\ C_6H_{12}O_6}{100\ g\ solution}$$

Multiply the mass of the solution by the conversion factor.

$$2000\ g\ solution \times \frac{2.8\ g\ C_6H_{12}O_6}{100\ g\ solution} = 56\ g\ C_6H_{12}O_6$$

3 Evaluate **Does the result make sense?** The prepared mass of the solution is 20 × 100 g. Since a 100-g sample of 2.8% (m/m) solution contains 2.8 g of solute, you need 20 × 2.8 g = 56 g of solute. To make the solution, mix 56 g of $C_6H_{12}O_6$ with 1944 g of solvent. (56 g of solute + 1944 g of solvent = 2000 g of solution)

18. Calculate the grams of solute required to make 250 g of 0.10% $MgSO_4$ (m/m).

16.2 LessonCheck

19. **Review** How do you calculate the molarity of a solution?

20. **Compare** How does the number of moles of solute before a dilution compare with the number of moles of solute after the dilution?

21. **Identify** What are two ways of expressing the concentration of a solution as a percent?

22. **Calculate** What is the molarity of a solution containing 400 g $CuSO_4$ in 4.00 L of solution?

23. **Calculate** How many milliliters of a stock solution of 2.00*M* KNO_3 would you need to prepare 100.0 mL of 0.150*M* KNO_3?

24. **Calculate** How many moles of solute are present in 50.0 mL of 0.20*M* KNO_3?

25. **Calculate** What is the concentration, in percent (v/v), of a solution containing 50 mL of diethyl ether ($C_4H_{10}O$) in 2.5 L of solution?

26. **Calculate** What mass of K_2SO_4 would you need to prepare 1500 g of 5.0% K_2SO_4 (m/m) solution?

BIGIDEA
THE MOLE AND QUANTIFYING MATTER

27. What information would you need in order to convert molarity to percent by volume?

Lesson Check Answers

19. If the number of moles and the volume of a solution is known, its molarity is determined by dividing the moles of solute by the volume of the solution.

20. Diluting a solution reduces the number of moles of solute per unit volume, but the total number of moles of solute in solution does not change.

21. Express the concentration as the ratio of the volume of the solute to the volume of the solution (v/v) or as the ratio of the mass of the solute to the mass of the solution (m/m).

22. $6.27 \times 10^{-1}M$ $CuSO_4$

23. 7.50 mL

24. 1.00×10^{-2} mol KNO_3

25. 2.0% (v/v) diethyl ether

26. 7.5×10^{1} g K_2SO_4

27. **BIG**IDEA *M* = mol of solute/L of solution; %(v/v) = volume of solute/volume of solution. You would need to know the molar mass and density of the solute in order to convert moles of solute to volume of solute.

Sample Practice Problem

How many grams of KI would you need to prepare 0.500 g of 7.0% KI (m/m) solution? *(35 grams)*

Evaluate

Informal Assessment

Have students compare percent by mass and percent by volume with molarity as ways of expressing the concentration of a solution. Have students write out a numbered list of steps they would follow to prepare a 1*M* aqueous solution of KCl. Then have students complete the 16.2 Lesson Check.

Reteach

Review the process of making dilutions. Stress to students that M_1 will always be greater than M_2, and V_1 will always be less than V_2. In other words, when making a dilution, molarity always decreases and volume always increases. Remind students that the only value that remains constant during a dilution is the moles of solute.

Answers

16. %(v/v) = 10 mL propanone/200 mL × 100% = 5.0% v/v

17. mL H_2O_2 = (400.0 mL × 3) / 100 = 1.2×10^{1} mL

18. 250 g solution × (10 g $MgSO_4$/100 g solution) = 25 g $MgSO_4$

CHEMISTRY & YOU Have students read the title of the feature, and draw their attention to the many types of foods shown in the photos that can be pickled. Encourage students to share their own experiences with either preparing or eating pickled foods. If possible, provide a variety of acid and brine pickles for students to examine.

Pose the following question to students: *Why do you think pickling is referred to as an* art *in the title of this feature?* You may need to guide students in the following ways:

- Consider how pickling relates to what you have studied so far in this chapter about solutions.
- The method of pickling varies for different types of food.
- Spices and herbs are added for flavor, but they have no effect on the pickling process itself. The amount of spice added is determined by personal preference.
- It is important to maintain the right concentration in a pickling solution in order to produce a pleasant-tasting food, achieve the proper texture, and avoid the development of harmful bacteria.

CHEMISTRY & YOU: EVERYDAY MATTER

Art of the Pickle

Every culture has its own version of the pickle, and the art of making pickles dates back to ancient history. The earliest known pickles were produced more than 4000 years ago using cucumbers native to India. In Korea, kimchi (pickled cabbage) has been produced for more than 3000 years. Ancient Egyptians and Greeks wrote about the nutritive value and healing power of pickles.

Nowadays, you can often count on the savory taste of a pickle when you order food at a restaurant or from a street vendor. Pickles come in many varieties. You might already know the taste of the dill pickles that accompany sandwiches, or the relish found at a hot dog stand. Other kinds of pickles include Japanese pickled ginger (often served with sushi), European pickled herring, and the hot pickled peppers found in some Mexican salsas.

Pickling is a way of preserving food using a solution of salt, acid (usually vinegar), spices, and/or sugar. Soaking vegetables and meats in the pickling solution prevents the growth of harmful bacteria and imparts a tangy, savory flavor to the food.

Main Types of Pickling

Pickling in Acid Solution

Process This type of pickling typically involves immersing and/or cooking vegetables for a few hours or days in a solution containing vinegar and spices. Vinegar is a 5% (v/v) aqueous solution of acetic acid ($C_2H_4O_2$).

Examples Acid solutions are used to prepare pickled ginger (above), pickled beets, bread-and-butter pickles, pickled herring, and hot dog relish.

Pickling in Brine Solution

Process In brine-based pickling, food is soaked in a salt solution called brine for 4 to 6 weeks. The brine encourages the growth of acid-producing bacteria. The concentration of the brine is usually 5–10% NaCl (m/m).

Examples Common brine pickles include dill cucumber pickles, sauerkraut (pickled fermented cabbage), Middle Eastern pickled turnips, and Indian mango pickles and chutneys.

532 Chapter 16 • Chemistry & You

21st Century Learning To be successful in the 21st century, students need skills and learning experiences that extend beyond subject matter mastery. The following project helps students build the following 21st Century Skills: *Creativity and Innovation, Communication and Collaboration, Information Literacy, Flexibility and Adaptability, Social and Cross-Cultural Skills, Productivity and Accountability, and Leadership and Responsibility.*

Pickled Peppers Pose the following challenge to students. *You've been hired by a well-known canning supply company to author an illustrated how-to booklet on the preparation of pickled peppers. Booklets should include the following:*

- A brief history and explanation of the use of pickling as a method of preserving food.
- Step-by-step instructions for pickling peppers, with metric measurements. For each step, write a sentence or two explaining why it is important.
- An explanation of the choice of brine solution (vinegar versus salt).
- Recipe credit and appropriate references.

SALTY SOLUTIONS As pickles soak, the salt in the solution encourages the growth of acid-producing bacteria, which prevent the growth of bacteria that cause spoilage. The salt concentration needs to be as exact as possible. If it's too high, the acid producers can't flourish; if it's too low, then not enough acid producers will grow, and your pickles may spoil.

Take It Further

1. Calculate A pickle recipe calls for 1.5 cups of pickling salt (NaCl) to be mixed with 1 gallon of water. If 1 cup of pickling salt has a mass of 220 grams, what is the percent by mass of NaCl in the pickling solution? (1 gal = 3785 cm^3)

2. Evaluate Is enough information given in the previous question to calculate the percent by volume of NaCl in the pickling solution? Explain your answer.

3. Calculate How many grams of pickling salt would you need to prepare 3500 g of 5.0% NaCl (m/m) solution for a batch of cucumber pickles?

Explain

MAKE A CONNECTION Help students connect the properties of solutions, principles of molarity, and concentration of solutions to the process of pickling. Have them read the Main Types of Pickling feature. Point out that brine pickling uses a 5–10% (m/m) NaCl solution. **Ask** If the concentration of a brine solution used for pickling is 5.0% NaCl (m/m), how many moles of NaCl are in 4.0 kg of solution? *(3.4 mol)* **Ask** Do you have enough information to calculate the molarity of the solution? Explain your answer. *(No; although you know how many moles of solute the solution contains, you do not know the volume of the solution. Only the mass of the solution is known. Molarity is moles of solute per unit volume of solution—not per unit mass of solution.)*

Extend

Connect to FOOD SCIENCE

One version of brine pickling involves soaking meats such as beef brisket in salt water, a process known as *corning*. During this process, salts move into the cells of the meat to equalize sodium chloride concentrations. The cells then absorb water to keep the overall solution concentrations the same. Draw a diagram on the board of a cell and the surrounding solution. Show students how salt and water migrate through the cell wall.

Differentiated Instruction

L1 STRUGGLING STUDENTS Work through this sample calculation before having students answer the Take It Further problem. Suppose the recipe calls for a 10% (m/m) brine solution using 350 g of salt. How many grams of solution does this recipe yield? *(3500 g)* How many grams of water are needed? *(3150 g)*

LPR LESS PROFICIENT READERS Work with students in small groups. Have them read each paragraph independently. Then lead them in discussing the main idea of the paragraph. Afterwards, have them write a sentence describing the paragraph. Continue with the remaining paragraphs.

L3 ADVANCED STUDENTS Commercial production of pickles requires that the pickling solutions be monitored very carefully to guarantee quality. Have students split into groups and research the large-scale production of a type of pickle. Have each group write a report detailing which physical properties of the pickling solution are controlled and how.

Answers

TAKE IT FURTHER

1. mass of solute = 1.5 cup NaCl × (220 g NaCl/1 cup) = 330 g NaCl; mass of solvent = 1 gal H_2O × (3785 cm^3/1 gal) × (1.0 g H_2O/1 cm^3) = 3785 g H_2O; mass of solution = 330 g NaCl + 3785 g H_2O = 4115 g; %(m/m) = 330 g NaCl/4115 g = 8.0% NaCl (m/m)
2. No; the volume of the solution is unknown.
3. 3500 g solution × (5.0 g NaCl/100 g solution) = 1.8×10^{-2} g NaCl

LESSON 16.3

Key Objectives

16.3.1 EXPLAIN how colligative properties can be explained on a particle basis.

Engage

CHEMISTRY & YOU Have students read the opening text. **Ask** What do you think would happen if you forgot to add rock salt to the ice in an ice-cream machine? *(The ice cream-mixture would not get cold enough to freeze.)* **Ask** What do you think would happen if you added too much salt to the ice in an ice-cream machine? *(The ice-cream mixture could freeze too quickly, making the texture of the resulting ice cream hard or crusty.)*

Activate Prior Knowledge

Have students write the chemical equations for the following examples to refresh their understanding of aqueous solutions.

- hydrochloric acid in water
  ($HCl(g) \rightarrow H^+(aq) + Cl^-(aq)$)
- magnesium chloride in water
  ($MgCl_2(s) \rightarrow Mg^{2+}(aq) + 2Cl^-(aq)$)
- glucose in water
  ($C_6H_{12}O_6(s) \rightarrow C_6H_{12}O_6(aq)$)

IN ACADEMIC STANDARDS for SCIENCE

C.7.1 Describe the composition and properties of types of solutions.

16.3 Colligative Properties of Solutions

C.7.1 Composition and properties of solutions

CHEMISTRY & YOU

Q: *Why do you need salt to make ice cream?* Here's a hint—it's *not* because ice cream is supposed to taste salty. Temperatures below 0°C are needed to make ice cream. Ice-cream makers know that if you add rock salt to ice, the mixture freezes at a few degrees below 0°C. In this lesson, you will discover how a solute can change the freezing point of a solution.

Key Question

What are three colligative properties of solutions?

Vocabulary

- colligative property
- freezing-point depression
- boiling-point elevation

Describing Colligative Properties

What are three colligative properties of solutions?

You already know that the physical properties of a solution differ from those of the pure solvent used to make the solution. After all, tea is not the same as pure water. But it might surprise you to learn that some of these differences in properties have little to do with the specific identity of the solute. Instead, they depend upon the mere presence of solute particles in the solution.

A **colligative property** is a property of solutions that depends only upon the number of solute particles, not upon their identity. **Three important colligative properties of solutions are vapor-pressure lowering, freezing-point depression, and boiling-point elevation.**

Vapor-Pressure Lowering Recall that vapor pressure is the pressure exerted by a vapor that is in dynamic equilibrium with its liquid in a closed system. A solution that contains a solute that is nonvolatile (not easily vaporized) always has a lower vapor pressure than the pure solvent, as shown in Figure 16.11. Glucose, a molecular compound, and sodium chloride, an ionic compound, are examples of nonvolatile solutes. When glucose or sodium chloride is dissolved in a solvent, the vapor pressure of the solution is lower than the vapor pressure of the pure solvent. Why is this true?

See vapor pressure *animated online.*

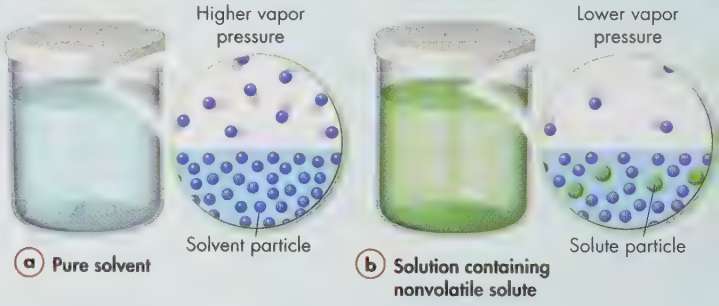

Figure 16.11 Vapor Pressure The vapor pressure of a solution of a nonvolatile solute is less than the vapor pressure of a pure solvent. **a.** Equilibrium is established between the liquid and vapor in a pure solvent. **b.** In a solution, solute particles reduce the number of solvent particles able to escape the liquid. Equilibrium is established at a lower vapor pressure.

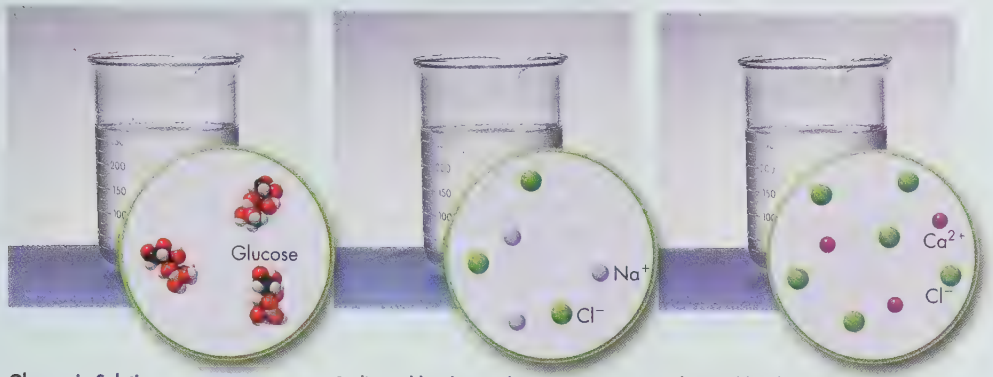

Focus on ELL

1 CONTENT AND LANGUAGE Write the words *property*, *depression*, and *elevation* on the board. Explain that these three words have both common and scientific meanings. Divide class into three groups, and assign one word to each group. Have groups look up the definitions for their word, then explain the similarities and differences between the common and scientific meanings to the rest of the class.

2 FRONTLOAD THE LESSON Have students share their experiences with antifreeze, car deicers, and road brine treatments. Tell students that each of these products work because of their colligative properties in solution.

3 COMPREHENSIBLE INPUT Use phase diagrams to help illustrate the effects of solutes on vapor pressure, boiling point, and freezing point of a solution. Have students investigate the Kinetic Art animation and perform the ice slurry/rock salt activity on page 536 as adjuncts to classroom discussion of vapor pressure and freezing-point depression, respectively.

Figure 16.12 Molecular vs. Ionic Solutes
Particle concentrations differ for dissolved molecular and ionic compounds in water.
Compare *Which solution has the lowest vapor pressure? The highest?*

Glucose in Solution
Three moles of glucose dissolved in water produce 3 mol of particles because glucose does not dissociate.

Sodium Chloride in Solution
Three moles of sodium chloride dissolved in water produce 6 mol of particles because each formula unit of NaCl dissociates into two ions.

Calcium Chloride in Solution
Three moles of calcium chloride dissolved in water produce 9 mol of particles because each formula unit of $CaCl_2$ dissociates into three ions.

In an aqueous solution of sodium chloride, sodium ions and chloride ions are dispersed throughout the liquid water. Both within the liquid and at the surface, the ions are surrounded by layers of associated water molecules, or shells of water of solvation. The formation of these shells of water of solvation reduces the number of solvent molecules that have enough kinetic energy to escape as vapor. Thus, the solution has a lower vapor pressure than the pure solvent (water) would have at the same temperature.

Ionic solutes that dissociate, such as sodium chloride and calcium chloride, have greater effects on the vapor pressure than does a nondissociating solute such as glucose. Recall that each formula unit of the sodium chloride (NaCl) produces two particles in solution, a sodium ion and a chloride ion.

$$NaCl(s) \xrightarrow{H_2O} Na^+(aq) + Cl^-(aq)$$

Each formula unit of calcium chloride ($CaCl_2$) produces three particles, a calcium ion and two chloride ions.

$$CaCl_2(s) \xrightarrow{H_2O} Ca^{2+}(aq) + 2Cl^-(aq)$$

When glucose dissolves, the molecules do not dissociate.

$$C_6H_{12}O_6(s) \xrightarrow{H_2O} C_6H_{12}O_6(aq)$$

Figure 16.12 compares the number of particles in three solutions of the same concentration. The decrease in a solution's vapor pressure is proportional to the number of particles the solute makes in solution. For example, the vapor-pressure lowering caused by 0.1 mol of sodium chloride in 1000 g of water is twice that caused by 0.1 mol of glucose in the same quantity of water. In the same way, 0.1 mol of $CaCl_2$ in 1000 g of water produces three times the vapor-pressure lowering as 0.1 mol of glucose in the same quantity of water.

READING SUPPORT
Build Study Skills: ***Concept Map***
As you read, construct a concept map that organizes the major ideas of this lesson. ***What factor determines the magnitude of colligative properties of solutions?***

Professional Development Note — Osmotic Pressure

Another colligative property, which is important in many biological processes, is osmotic pressure. Osmotic pressure is the tendency for solvent to flow through a semipermeable membrane from a region of low solute concentration to a region of higher solute concentration. This process helps regulate the movement of fluids across cell membranes. Cells remain healthy as long as they are continually bathed in an isotonic medium, which maintains the correct osmotic balance between the inside and outside of the cell membrane. Physicians make use of the osmotic effect to treat patients with kidney failure. Afflicted individuals undergo dialysis, a process in which the blood is circulated through a machine equipped with a semipermeable membrane. In the machine, osmotic pressure is used to separate waste materials from the blood.

Foundations for Reading

BUILD VOCABULARY Explain that the adjective *colligative* comes from the Latin *colligare,* meaning "to tie." Explain that a colligative property is one in which particles are seemingly tied together in their actions and act as a group rather than as individuals.

READING STRATEGY Have students create a main ideas and details chart to organize their notes on this lesson. Encourage students to add drawings to their charts to clarify important concepts.

Explain

Describing Colligative Properties

MAKING CONNECTIONS Remind students that ionic compounds and certain molecular compounds, such as HCl, produce two or more particles when they dissolve in water. Most molecular compounds, such as glucose, do not dissociate when they dissolve in water. For each formula unit of $MgCl_2$ that dissolves, three particles are formed in solution. **Ask** How many particles are formed when $FeCl_3$ dissolves in water? *(4)*

USE VISUALS Direct students to Figure 16.12. Emphasize that colligative properties do not depend on the type of particles; rather, they depend on the concentration. For colligative properties, a mole of one kind of particle has the same effect as a mole of any other kind of particle. **Ask** Which produces a greater change in colligative properties—an ionic solid or a molecular solid? *(An ionic solid produces a greater change because it will produce two or more moles of ions for every mole of solid that dissolves.)*

Answers

FIGURE 16.12 The glucose solution has the highest vapor pressure; the calcium chloride solution has the lowest vapor pressure.

Explore

Class Activity

PURPOSE To observe the freezing point depression of ice by the addition of rock salt (NaCl) to a slurry of ice-water

MATERIALS thermometer, foam cup, rock salt, water, ice.

PROCEDURE Have students make an ice-water slurry in their cups. Ask them to measure the initial temperature of the ice-water slurry and the lowest temperature reached after the addition of the rock salt. Explain that the observed difference in temperature is the freezing point depression for this solution of NaCl in water.

Freezing-Point Depression When a substance freezes, the particles of the solid take on an orderly pattern. The presence of a solute in water disrupts the formation of this pattern because of the shells of water of solvation. As a result, more kinetic energy must be withdrawn from a solution than from the pure solvent to cause the solution to solidify. The freezing point of a solution is lower than the freezing point of the pure solvent. The difference in temperature between the freezing point of a solution and the freezing point of the pure solvent is called the **freezing-point depression.**

Freezing-point depression is another colligative property. The magnitude of the freezing-point depression is proportional to the number of solute particles dissolved in the solvent and does not depend upon their identity. The addition of 1 mol of solute particles to 1000 g of water lowers the freezing point by 1.86°C. For example, if you add 1 mol (180 g) of glucose to 1000 g of water, the solution freezes at −1.86°C. However, if you add 1 mol (58.5 g) of sodium chloride to 1000 g of water, the solution freezes at −3.72°C, double the change for glucose. This difference occurs because 1 mol NaCl produces 2 mol of particles and, thus, doubles the freezing-point depression.

The freezing-point depression of aqueous solutions plays an important role in helping to keep travelers safe in cold, icy weather. The truck in Figure 16.13 spreads a layer of salt on the icy road to make the ice melt. The melted ice forms a solution with a lower freezing point than that of pure water. Similarly, ethylene glycol ($C_2H_6O_2$, antifreeze) is added to the water in automobile cooling systems to depress the freezing point of the water below 0°C. Automobiles can thus withstand subfreezing temperatures without freezing up.

Figure 16.13 De-icing Measures
Roads can be free of ice even at temperatures below 0°C if salt is applied. A common de-icer used on aircraft is a mixture of water and propylene glycol.
Infer *Why do you think $CaCl_2$ is a more effective road de-icer than NaCl?*

UbD Check for Understanding

BIGIDEA **THE MOLE AND QUANTIFYING MATTER** Provide students with a handout copy of Figure 16.12, without the explanatory text. Have students write a one-minute summary on the handout that explains why the three solutions have different freezing points and boiling points, despite the fact that their molar concentrations are equal.

ADJUST INSTRUCTION If students are having difficulty writing their summaries, review the equations in the text on page 535. Have students compare the number of representative particles that result when each solid is dissolved in water. Then, allow students to revise their summaries as needed.

Figure 16.14 Antifreeze
The fluid circulating through a car's cooling system is a solution of water and ethylene glycol, or antifreeze. The resulting mixture freezes below 0°C and boils above 100°C.

Boiling-Point Elevation The boiling point of a substance is the temperature at which the vapor pressure of the liquid phase equals atmospheric pressure. As you just learned, adding a nonvolatile solute to a liquid solvent decreases the vapor pressure of the solvent. Because of the decrease in vapor pressure, additional kinetic energy must be added to raise the vapor pressure of the liquid phase of the solution to atmospheric pressure and initiate boiling. Thus, the boiling point of a solution is higher than the boiling point of the pure solvent. The difference in temperature between the boiling point of a solution and the boiling point of the pure solvent is the **boiling-point elevation.**

Figure 16.14 shows antifreeze being poured into a car's coolant tank. The antifreeze doesn't just lower the freezing point of the water in the cooling system. It also elevates the boiling point, which helps protect the engine from overheating in the summer.

Boiling-point elevation is a colligative property; it depends on the concentration of particles, not on their identity. Therefore, you can think about boiling-point elevation in terms of particles. It takes additional kinetic energy for the solvent particles to overcome the attractive forces that keep them in the liquid. Thus, the presence of a solute elevates the boiling point of the solvent. The magnitude of the boiling-point elevation is proportional to the number of solute particles dissolved in the solvent. The boiling point of water increases by 0.512°C for every mole of particles that the solute forms when dissolved in 1000 g of water.

CHEMISTRY & YOU

Q: *Solutes other than NaCl could be used to produce the same freezing-point depression in an ice-cream machine. What factors do you think make NaCl a good choice?*

16.3 LessonCheck

28. Identify Name three colligative properties of solutions.

29. Explain Why does a solution have a lower vapor pressure than the pure solvent of that solution?

30. Explain Why does a solution have a depressed freezing point and an elevated boiling point compared with the pure solvent?

31. Compare Would a dilute or a concentrated sodium fluoride solution have a higher boiling point? Explain.

32. Compare An equal number of moles of KI and MgI_2 are dissolved in equal volumes of water. Which solution has the higher
- **a.** boiling point?
- **b.** vapor pressure?
- **c.** freezing point?

33. Apply Concepts Review what you learned in Lesson 13.2 about the relationship between the vapor pressure of liquids and their boiling points. Explain why only nonvolatile solutes cause the elevation of the solvent's boiling point.

Lesson Check Answers

28. vapor-pressure lowering, boiling-point elevation, and freezing-point depression

29. Formation of solvation shells around solute particles reduces the number of water molecules with sufficient kinetic energy to escape the solution. Therefore, the vapor pressure is lower relative to pure solvent.

30. Because vapor pressure has been reduced, more kinetic energy is needed to reach the boiling point. For a solution to freeze, it must lose more kinetic energy than the pure solvent does.

31. concentrated sodium fluoride, because the magnitude of the boiling-point elevation is proportional to the number of solute particles dissolved in the solvent

32. **a.** MgI_2 solution
b. KI solution
c. KI solution

33. Volatile solutes quickly evaporate at higher temperatures and so would not be present to cause the elevation of the solvent's boiling point.

Explain

CRITICAL THINKING Ask a student volunteer to explain how a car's cooling system works. Include visuals if time allows. Lead a discussion comparing the consequences of cooling a car engine with pure water to those of using antifreeze in the cooling system. Point out that, when water freezes, it must form a crystalline lattice. Encourage students to think about what effect adding a solute has on the ability of water to form that lattice readily at normal freezing temperatures.

CHEMISTRY & YOU Compared to other ionic solids, NaCl is inexpensive and also food-safe (in case it accidentally comes into contact with the ice-cream mixture).

Evaluate

Informal Assessment

Have students explain, using words or diagrams, how the addition of solute particles to a solvent causes the vapor pressure and freezing point of the solution to decrease relative to the pure solvent and the boiling point to increase. Then, have students complete the 16.3 Lesson Check.

Reteach

Guide students to understand that colligative properties are those physical properties of solutions that depend only on the number of particles of solute in solution and not on the chemical composition of the particles. Explain that the magnitudes of the observed physical changes are proportional to the quantity of solute particles in solution.

Answers

FIGURE 16.13 $CaCl_2$ produces three ions in solution; NaCl produces two.

C.7.3 Describe the concentration of solutes in solution in terms of molarity. Perform calculations using molarity, mass, and volume.

16.4 Calculations Involving Colligative Properties

C.7.1 Composition and properties of solutions; C.7.3 Molarity

CHEMISTRY & YOU

Q: *How hot is a pot of boiling pasta?* Cooking instructions for a wide variety of foods, from dried pasta to fresh vegetables, often call for the addition of a small amount of salt to the cooking water. Most people like the flavor of food cooked with salt.

But adding salt can have another effect on the cooking process. Recall that dissolved salt elevates the boiling point of water. Suppose you added a teaspoon of salt to two liters of water. A teaspoon of salt has a mass of about 20 g. Would the resulting boiling-point increase be enough to shorten the time required for cooking? In this lesson, you will learn how to calculate the amount the boiling point of the cooking water would rise.

Key Questions

What are two ways of expressing the ratio of solute to solvent in a solution?

How are freezing-point depression and boiling-point elevation related to molality?

Vocabulary

- molality (m)
- mole fraction
- molal freezing-point depression constant (K_f)
- molal boiling-point elevation constant (K_b)

Molality and Mole Fraction

What are two ways of expressing the ratio of solute to solvent in a solution?

Recall that colligative properties of solutions depend only on the number of solute particles dissolved in a given amount of solvent. **Chemists use two ways to express the ratio of solute particles to solvent particles: in molality and in mole fractions.**

Molality (m) is the number of moles of solute dissolved in 1 kilogram (1000 grams) of solvent. Molality is also known as molal concentration.

$$\text{Molality } (m) = \frac{\text{moles of solute}}{\text{kilogram of solvent}}$$

Note that molality is not the same as molarity. Molality refers to moles of solute per kilogram of solvent rather than moles of solute per liter of solution. In the case of water as the solvent, 1 kg or 1000 g equals a volume of 1000 mL, or 1 L.

You can prepare a solution that is 1.00 molal (1m) in glucose, for example, by adding 1.00 mol (180 g) of glucose to 1000 g of water. A 0.500 molal (0.500m) sodium chloride solution is prepared by dissolving 0.500 mol (29.3 g) of NaCl in 1.000 kg (1000 g) of water.

Focus on ELL

1 CONTENT AND LANGUAGE Provide students with a spider diagram. Have them write the word *molality* in the center circle. As students progress through the lesson, have them add any new concepts to their diagram. Stop often and help students pronounce the words on their diagrams. Take this time to verify that students understand how the concepts relate to *molality*.

2 FRONTLOAD THE LESSON Explain to students that this lesson involves the term *molality*, which sounds and looks the very similar to another term that they recently learned, *molarity*. Point out that both terms apply to solutions. Work with students to develop a visual or verbal cue to verify which term is being used in order to avoid confusion due to pronunciation similarities.

3 COMPREHENSIBLE INPUT Explain Figure 16.16 and restate information in its caption as needed. Read the question aloud, and provide students with their own copy of the graph. As you discuss the questions, have students write notes on the graph. Then, have students access the figure's associated Virtual Lab.

Sample Problem 16.7

Using Molality

How many grams of potassium iodide must be dissolved in 500.0 g of water to produce a 0.060 molal KI solution?

1 Analyze **List the knowns and the unknown.**

According to the definition of molality, the final solution must contain 0.060 mol KI per 1000 g H_2O. Use the molality as a conversion factor to convert from mass of the solvent (H_2O) to moles of the solute (KI). Then use the molar mass of KI to convert from mol KI to g KI. The steps are as follows: mass of H_2O ⟶ mol KI ⟶ g KI.

KNOWNS

mass of water = 500.0 g = 0.5000 kg
solution concentration = 0.060*m*
molar mass of KI = 166.0 g/mol

UNKNOWN

mass of solute = ? g KI

2 Calculate **Solve for the unknown.**

Identify the conversion factor based on 0.060*m* that allows you to convert from g H_2O to mol KI.

$$\frac{0.060 \text{ mol KI}}{1.000 \text{ kg } H_2O}$$

Identify the conversion factor based on the molar mass of KI that allows you to convert from mol KI to g KI.

$$\frac{166.0 \text{ g KI}}{1 \text{ mol KI}}$$

Multiply the known solvent volume by the conversion factors.

$$0.5000 \text{ kg } H_2O \times \frac{0.060 \text{ mol KI}}{1.000 \text{ kg } H_2O} \times \frac{166.0 \text{ g KI}}{1 \text{ mol KI}} = 5.0 \text{ g KI}$$

To make the 0.060-molal KI solution, you would dissolve 5.0 g of KI in 500.0 g of water.

3 Evaluate **Does this result make sense?** A 1-molal KI solution is one molar mass of KI (166.0 g) dissolved in 1000 g of water. The desired molal concentration (0.060*m*) is about $\frac{1}{20}$ of that value, so the mass of KI should be much less than the molar mass. The answer is correctly expressed to two significant figures.

34. How many grams of sodium fluoride are needed to prepare a 0.400*m* NaF solution that contains 750 g of water?

35. Calculate the molality of a solution prepared by dissolving 10.0 g NaCl in 600 g of water.

Remember: Molality equals moles of solute dissolved per kilogram of solvent.

Foundations for Math

METRIC CONVERSIONS It may make more sense to some students to immediately convert all given quantities to the desired unit in a problem.

In **Sample Problem 16.7,** the mass of the water is given in grams, molar mass is measured in grams/mol, and the desired unit of KI is grams. The only quantity not given in grams is the molality, which is always given in moles per kilogram. Tell students they will arrive at the same answer if they begin by converting molality to moles per *x* grams. **Ask** How many grams are in 1 kilogram? *(1,000)* **Ask** How can you write molality in terms of grams? *(mol/kg = mol/1000 g)* Solve by writing molality in terms of grams:

500 g H_2O × (0.060 mol KI/1000 g H_2O) × (166.0 g KI/1 mol KI).

Show each of the units cancelling to arrive at a final solution of 4.98 g KI, which rounds to 5.0 g KI.

Foundations for Reading

BUILD VOCABULARY Have students create a three-column chart for each vocabulary term. Students can use the chart to organize the terms, definitions, and associated mathematical formulas.

READING STRATEGY Prior to the lesson, have students write down what they know about fractions, moles, freezing points, and boiling points. Then, have students preview the chapter. Ask students to circle the items on their list that will be useful for this lesson. Then, have students write down any concerns they may have about concepts that seem familiar, but are in fact different.

Explain

Molality and Mole Fraction

APPLY CONCEPTS Write the expressions defining molarity and molality on the board. Compare the chemical quantities in each expression. Point out that molarity is denoted by *M* and molality by *m*. Explain that the molality of a solution does not vary with temperature because the mass of the solvent does not change. In contrast, the molarity of a solution does vary with temperature because the liquid can expand and contract. Tell students that when studying colligative properties such as boiling-point elevation and freezing-point depression, it is preferable to use a concentration that does not depend on temperature.

Sample Practice Problem

How many grams of potassium bromide must be dissolved in 0.750 kg of water to produce a 0.150 molal KBr solution? *(13.4 g)*

Answers

34. 750 g water × (0.400 mol NaF/1000 g water) × (42.0 g NaF/1 mol NaF) = 1.26×10^1 g NaF

35. (10.0 g NaCl/600 g water) × (1 mol NaCl/58.5 g NaCl) × (1000 g water/1 kg water) = 2.85×10^{-1}*m* NaCl

Explain

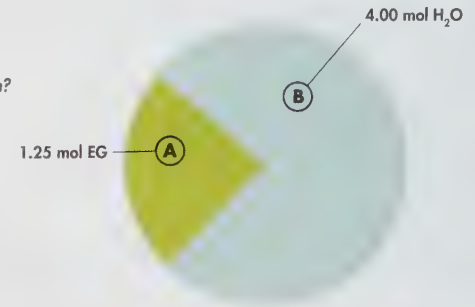
MAKE A CONNECTION Guide students to understand that the mole fraction compares the number of moles of a solute to the total number of moles in the solution. Explain that organic chemists, who frequently work with non-aqueous solvent systems, often use this method of expressing concentration. Tell students that the mole fraction is also used when calculating the vapor pressure of a solution.

Explore

Class Activity

PURPOSE Students will organize various methods used to calculate the concentration of a solution.

PROCEDURE Have students design a diagram that includes a definition of each type of concentration unit. More than one design is possible, but each should include the terms *concentration of a solution, percent by mass, percent by volume, molarity, molality, and mole fraction.* Students may wish to include additional detail by showing interconversions between mass of solute and moles of solute. Underneath each concentration unit, students should provide examples of when the unit would be used in the laboratory and in everyday life.



The concentration of a solution also can be expressed as a mole fraction. The **mole fraction** of a solute in a solution is the ratio of the moles of that solute to the total number of moles of solvent and solute. In a solution containing n_A mol of solute A and n_B mol of solvent B, the mole fraction of solute A (X_A) and the mole fraction of solvent B (X_B) can be expressed as follows:

$$X_A = \frac{n_A}{n_A + n_B} \qquad X_B = \frac{n_B}{n_A + n_B}$$

Note that mole fraction is a dimensionless quantity. The sum of the mole fractions of all the components in a solution equals unity, or one.

Figure 16.15 below and Sample Problem 16.8 on the next page illustrate how to calculate the mole fractions of the solute and solvent for a solution of ethylene glycol (EG) in water.

Figure 16.15 Mole Fraction
Ethylene glycol (EG) is added to water as antifreeze in the proportions shown. A mole fraction is the ratio of the number of moles of one substance to the total number of moles of all substances in the solution.
Infer *What is the sum of all mole fractions in a solution?*

$$\text{Total moles} = (A) + (B) = 5.25 \text{ mol}$$

$$\text{Mole fraction EG} = \frac{(A)}{(A)+(B)} = \frac{1.25}{5.25}$$

$$\text{Mole fraction } H_2O = \frac{(B)}{(A)+(B)} = \frac{4.00}{5.25}$$

Freezing-Point Depression and Boiling-Point Elevation

How are freezing-point depression and boiling-point elevation related to molality?

Depressions of freezing points and elevations of boiling points are usually quite small. For example, if you add a teaspoon of salt to a pot of water and boil the resulting solution, you will have a hard time detecting any change in the boiling point using a cooking thermometer. It turns out that the elevation is just a small fraction of a degree Celsius. To measure colligative properties accurately, you would need a thermometer that can measure temperatures to the nearest 0.001°C.

Another way to determine the magnitudes of colligative properties is by calculating them. You can do this if you know the molality of the solution and some reference data about the solvent.

Differentiated Instruction

LPR LESS PROFICIENT READERS Have students write sentences using the words *molarity* and *molality*, and have them circle the letter in each word that makes them distinct. The mnemonic, "r" for *molarity* and "l" for *liter* may help.

L1 SPECIAL NEEDS STUDENTS Use fraction models or pie models when introducing mole fractions. Use only whole numbers in simple examples until students understand the relationship.

L3 ADVANCED STUDENTS The wood frog is an amphibian that can survive being frozen. Scientists believe that the frog's cells contain a substance that acts as a natural antifreeze. Have students research wood frogs and other animals with this ability, and report back on current theories on the identity of the substance or substances responsible for protecting the animals' cells.

Sample Problem 16.8

Calculating Mole Fractions

Ethylene glycol (EG, or $C_2H_6O_2$) is added to automobile cooling systems to protect against cold weather. What is the mole fraction of each component in a solution containing 1.25 mol of ethylene glycol and 4.00 mol of water?

1 Analyze **List the knowns and the unknowns.**

The given quantities of solute (EG) and solvent (water) are expressed in moles. Use the equations for mole fraction of a solute and mole fraction of a solvent to solve this problem. (The pie graph in Figure 16.15 gives you a visual representation of the mole fraction of each component.)

KNOWNS

moles of ethylene glycol (n_{EG}) = 1.25 mol EG

moles of water (n_{H_2O}) = 4.00 mol H_2O

UNKNOWNS

mole fraction EG (X_{EG}) = ?

mole fraction H_2O (X_{H_2O}) = ?

2 Calculate **Solve for the unknowns.**

Write the equation for the mole fraction of ethylene glycol (X_{EG}) in the solution.

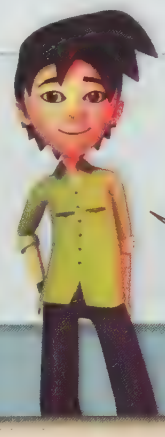
$$X_{EG} = \frac{n_{EG}}{n_{EG} + n_{H_2O}}$$

Note that the denominator for each mole fraction is the same: the total number of moles of solvent and solute in the solution.

Write the equation for the mole fraction of water (X_{H_2O}) in the solution.

$$X_{H_2O} = \frac{n_{H_2O}}{n_{EG} + n_{H_2O}}$$

Substitute the known values into each equation.



$$X_{EG} = \frac{n_{EG}}{n_{EG} + n_{H_2O}} = \frac{1.25\ \cancel{mol}}{1.25\ \cancel{mol} + 4.00\ \cancel{mol}} = 0.238$$

$$X_{H_2O} = \frac{n_{H_2O}}{n_{EG} + n_{H_2O}} = \frac{4.00\ \cancel{mol}}{1.25\ \cancel{mol} + 4.00\ \cancel{mol}} = 0.762$$

3 Evaluate **Does the result make sense?** The sum of the mole fractions of all the components in the solution equals 1 ($X_{EG} + X_{H_2O} = 1.000$). Each answer is correctly expressed to three significant figures.

36. What is the mole fraction of each component in a solution made by mixing 300 g of ethanol (C_2H_6O) and 500 g of water?

37. A solution contains 50.0 g of carbon tetrachloride (CCl_4) and 50.0 g of chloroform ($CHCl_3$). Calculate the mole fraction of each component in the solution.

Remember: Mole fraction is a mole ratio, not a mass ratio. If the given quantities are masses, you must first convert each mass to moles using the molar mass of the substance.

Foundations for Math

FRACTIONS Point out that a mole fraction is simply a ratio that compares a part to a whole. Explain that calculating mole fractions is the same as determining the parts in any other whole, such as slices in a pizza. Therefore, the sum will always be unity, or 1.

In **Sample Problem 16.8,** stress that the formula may look intimidating, but that it simply represents the ratio of parts to the whole, given that the quantities are in moles. Point out that the mole fraction for water is the ratio of water to the total quantity of solution, and the mole fraction for ethylene glycol is the ratio of ethylene glycol to the total quantity of solution.

Sample Practice Problem

Calculate the mole fraction of each component in a solution of 42 g CH_3OH, 35 g C_2H_5OH, and 50 g C_3H_7OH. *(X_{CH_3OH} = 0.45; $X_{C_2H_5OH}$ = 0.26; $X_{C_3H_7OH}$ = 0.29)*

Answers

FIGURE 16.16 1 (unity)

36. $X_{C_2H_5OH} = 0.190; X_{H_2O} = 0.810$

37. $X_{H_2O} = 0.972; X_{C_{12}H_{22}O_{11}} = 0.028$

Explain

Freezing-Point Depression and Boiling-Point Elevation

USE VISUALS Display Figure 16.16 on an overhead projector. Choose an arbitrary concentration for an aqueous solution of NaCl or ethylene glycol. Calculate the boiling-point elevation and freezing-point depression. Then, write the temperatures on the horizontal axis. Show students how to read the data for the boiling points of the pure solvent and of the solution. Then, have students read the corresponding values for the freezing points. **Ask** What are ΔT_b and ΔT_f for this solution? *(Point out that the solute affects both the freezing point and boiling point of a liquid.)*

CRITICAL THINKING Have students consider the usefulness of boiling-point elevation and freezing-point depression calculations in formulating automobile antifreeze. **Ask** Why would knowing the boiling-point elevation and freezing-point depression be important when choosing antifreeze for car radiators? *(Despite its name, antifreeze protects against both freezing and overheating.)*

MISCONCEPTION ALERT Some students may think that freezing points and boiling points can be depressed or elevated without end. Explain that as the concentration of a solute, such as ethylene glycol, increases, there comes a point when the quantity of solute exceeds the quantity of solvent. Ethylene glycol becomes the solvent and water becomes the solute; the trends in colligative properties begin to reflect ethylene glycol instead of water. Explain that if the solute is a solid, such as NaCl, eventually the solution becomes saturated. But point out that even before this saturation point is reached, the magnitude of certain colligative properties may reach a maximum.

VIRTUAL LAB **InterpretGraphs**

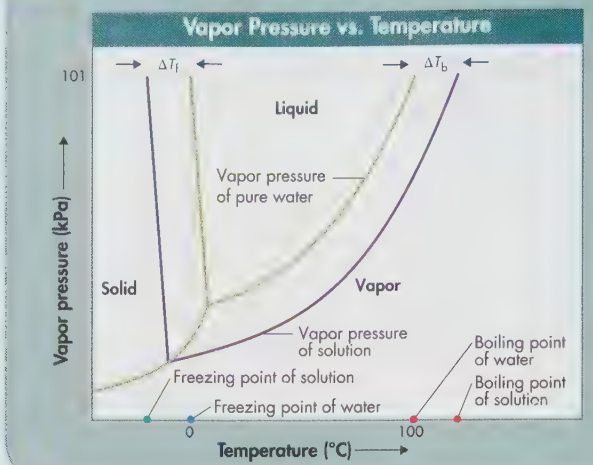


Figure 16.16 The graph shows the relationship between vapor pressure and temperature for pure water and aqueous solutions.

a. Read Graphs What is the freezing point of water? What is the boiling point?

b. Compare How do the freezing and boiling points of the solution compare to those of pure water?

c. Draw Conclusions Does adding a solute to water allow it to remain as a liquid over a longer or shorter temperature range? Explain.

The graph in Figure 16.16 shows that the freezing point of a solvent is lowered, and its boiling point is raised, by the addition of a nonvolatile solute. **The magnitudes of the freezing-point depression (ΔT_f) and the boiling-point elevation (ΔT_b) of a solution are directly proportional to the molal concentration (m), assuming the solute is molecular, not ionic.**

$$\Delta T_f \propto m$$
$$\Delta T_b \propto m$$

Table 16.2
K_f and K_b Values for Some Common Solvents

Solvent	K_f (°C/m)	K_b (°C/m)
Acetic acid	3.90	3.07
Benzene	5.12	2.53
Camphor	37.7	5.95
Cyclohexane	20.2	2.79
Ethanol	1.99	1.19
Nitrobenzene	7.00	5.24
Phenol	7.40	3.56
Water	1.86	0.512

The change in the freezing temperature (T_f) is the difference between the freezing point of the solution and the freezing point of the pure solvent. Similarly, the change in the boiling temperature (T_b) is the difference between the boiling point of the solution and the boiling point of the pure solvent. The term m is the molal concentration of the solution.

With the addition of a constant, the proportionality between the freezing point depression (ΔT_f) and the molality m can be expressed as an equation.

$$\Delta T_f = K_f \times m$$

The constant, K_f, is the **molal freezing-point depression constant,** which is equal to the change in freezing point for a 1-molal solution of a nonvolatile molecular solute. The value of K_f depends upon the solvent. Its units are °C/m. Table 16.2 lists the K_f values for water and some other solvents.

UbD Check for Understanding

BIGIDEA THE MOLE AND QUANTIFYING MATTER Have students write one-minute summaries comparing and contrasting molarity and molality.

ADJUST INSTRUCTION If students are having difficulty with their summaries, write the formulas for each quantity on the board, highlighting the differences in a different color. Then, review the appropriate times to use each quantity.

Sample Problem 16.9

Calculating the Freezing-Point Depression of a Solution

Antifreeze protects a car from freezing. It also protects it from overheating. Calculate the freezing-point depression of a solution containing exactly 100 g of ethylene glycol ($C_2H_6O_2$) antifreeze in 0.500 kg of water.

1 Analyze **List the knowns and the unknown.** Calculate the number of moles of $C_2H_6O_2$ and the molality of the solution. Then calculate the freezing-point depression using $\Delta T_f = K_f \times m$.

KNOWNS
- mass of $C_2H_6O_2$ = 100 g
- mass of water = 0.500 kg
- K_f for H_2O = 1.86°C/m
- molar mass of $C_2H_6O_2$ = 62.0 g/mol

UNKNOWN
- ΔT_f = ?°C

2 Calculate **Solve for the unknown.**

Use the molar mass of $C_2H_6O_2$ to convert the mass of solute to moles.

$$100\ \text{g}\ C_2H_6O_2 \times \frac{1\ \text{mol}\ C_2H_6O_2}{62.0\ \text{g}\ C_2H_6O_2} = 1.61\ \text{mol}\ C_2H_6O_2$$

Calculate the molality of the solution.

$$m = \frac{\text{mol solute}}{\text{kg solvent}} = \frac{1.61\ \text{mol}}{0.500\ \text{kg}} = 3.22m$$

Calculate the freezing-point depression.

$$\Delta T_f = K_f \times m = 1.86°\text{C}/m \times 3.22m = 5.99°\text{C}$$

The freezing point of the solution is 0.00°C − 5.99°C = −5.99°C.

3 Evaluate **Does the result make sense?** A 1-molal solution reduces the freezing temperature by 1.86°C, so a decrease of 5.99°C for an approximately 3-molal solution is reasonable.

38. What is the freezing-point depression of an aqueous solution of 10.0 g of glucose ($C_6H_{12}O_6$) in 50.0 g H_2O?

39. Calculate the freezing-point depression of a benzene solution containing 400 g of benzene and 200 g of the molecular compound acetone (C_3H_6O). K_f for benzene is 5.12°C/*m*.

As you might expect, the boiling-point elevation of a solution can also be expressed as an equation. In this case, the proportionality constant is K_b, the **molal boiling-point elevation constant,** which is equal to the change in boiling point for a 1-molal solution of a nonvolatile molecular solute.

$$\Delta T_b = K_b \times m$$

Table 16.2 lists the K_b values for some solvents. Like K_f, K_b has units of °C/*m*.

Sample Problem 16.9 above described how to determine ΔT_f if the solute is a molecular compound. But for ionic compounds, both ΔT_f and ΔT_b depend upon the number of ions produced by each formula unit. This number is used to calculate an effective molality, as you'll see in Sample Problem 16.10.

CHEMISTRY & YOU

Q: *Does pasta cook at 100°C? After you read Sample Problem 16.10, calculate the boiling-point elevation for the solution described at the beginning of the lesson on page 538.*

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the Small-Scale Lab on page 545. Make sure each group has ELLs of varied language proficiencies, so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Recreate the procedure as a numbered list of steps to follow. Model the procedure for students.

INTERMEDIATE: LOW/HIGH Provide students with an organized and labeled chart to complete during the Analyze and Conclude section.

ADVANCED: LOW/HIGH Have students create their own data chart to record the answers to their Analyze and Conclude calculations.

Extend

Have students consider the following question: *Which aqueous solution would have the larger boiling-point elevation and freezing-point depression: 1m KCl or 1m $CaBr_2$?* Challenge students to answer the question, and use their knowledge of molality, boiling-point elevation, and freezing-point depression to justify their choice. *($CaBr_2$; because both solutes are ionic, their effects on freezing-point depression and boiling-point elevation are determined by the number of particles each places into solution. Even though both solutions have a molality of 1, the solution $CaBr_2$ contains 3 mol of ions per kilogram of water, and the KCl solution contains 2 mol of ions per kilogram of water. Theoretically, the $CaBr_2$ solution will exhibit a freezing-point depression and boiling-point elevation one and one-half times as great as those exhibited by the KCl solution.*

CHEMISTRY & YOU $\Delta T_b = 0.09°\text{C}$

Sample Practice Problem

What is the freezing point of a 0.800*m* aqueous solution of glucose, given that K_f for H_2O = 1.86°C/*m*.*(–1.49°C)*

Answers

INTERPRET GRAPHS

a. 0°C; 100°C

b. The freezing point of the solution is lower than that of pure water and the boiling point is higher than that of pure water.

c. Adding a solute to water allows it to remain as a liquid over a longer temperature range because the solution changes to a solid at a lower temperature and changes to a vapor at a higher temperature.

38. mol $C_6H_{12}O_6$ = 10.0 g glucose × (1 mol/180.2 g) = 0.0556 mol; m = (0.0556 mol/50.0 g H_2O) × (1000 g/1 kg) = 1.11*m*; $\Delta T_f = K_f \times m$ = 1.86°C/*m* × 1.11*m* = 2.06°C

39. mol C_3H_6O = 200 g C_3H_6O × (1 mol/58.0 g C_3H_6O) = 3.45 mol C_3H_6O; m = (3.45 mol C_3H_6O/400 g) × (1000 g/1 kg) = 8.63*m*; $K_f \times m$ = 5.12°C/*m* × 8.63*m* = 44.2°C

Explain

Sample Practice Problem

What is the boiling point of a solution containing 96.7 g of sucrose ($C_{12}H_{22}O_{11}$) in 250.0 g water at 1 atm? *(100.579°C)*

Evaluate

Informal Assessment

Assess students' understanding of colligative properties by posing the following questions.

Ask Which solution has a higher boiling point, 1 mol of $Al(NO_3)_3$ in 1000 g of water or 1.5 mol of KCl in 1000 g of water? Have students explain their answers. *(The solution of $Al(NO_3)_3$ has a higher boiling point because $Al(NO_3)_3$ dissociates into a larger number of particles.)* **Ask** Does volatility affect the colligative properties of a compound? Explain. *(Yes; Volatile solutes quickly evaporate at higher temperatures, which would change the molal concentration of the solution.)*

Then, have students complete the 16.4 Lesson Check.

Reteach

Remind students that when they do calculations involving ionic solids, they must find the molality of the solution in terms of the total number of particles. Work through several examples to be sure they understand this important point.

Answers

40. m = (1.25 mol $CaCl_2$/1400 g) × (1000 g/1 kg) = 0.893m $CaCl_2$; each formula unit of $CaCl_2$ dissociates into three particles; 0.893m $CaCl_2$ × 3 = 2.68m; $\Delta T_b = K_b \times m$ = 0.512°C/m × 2.68m = 1.37°C; 100°C + 1.37°C = 101.37°C

41. 2.00°C/0.512°C/m = 3.91m; Each formula unit of NaCl dissociates into two particles; 3.91m/2 = 1.96m; in 1 kg of water, 1.96 mol NaCl × (58.5 g/1 mol) = 115 g NaCl

Sample Problem 16.10

Calculating the Boiling Point of a Solution

What is the boiling point of a 1.50m NaCl solution?

1 Analyze **List the knowns and the unknown.** Each formula unit of NaCl dissociates into two particles, according to the equation $NaCl(s) \longrightarrow Na^+(aq) + Cl^-(aq)$. Based on the total number of dissociated particles, the effective molality is 2 × 1.50m = 3.00m. Calculate the boiling-point elevation (using the equation $\Delta T_b = K_b \times m$), and then add it to 100°C.

KNOWNS

solution concentration = 1.50m NaCl

K_b for H_2O = 0.512°C/m

UNKNOWN

boiling point = ?°C

2 Calculate **Solve for the unknown.**

Calculate the boiling-point elevation, making sure to use the molality of total dissociated particles in solution.

$\Delta T_b = K_b \times m$ = 0.512°C/m × 3.00m = 1.54°C

Calculate the boiling point of the solution.

T_b = 100°C + 1.54°C = 101.54°C

3 Evaluate **Does the result make sense?** The boiling point increases about 0.5°C for each mole of solute particles, so the total change is reasonable. Because the boiling point of water is defined as exactly 100°C, this value does not limit the number of significant figures in the solution of the problem.

40. What is the boiling point of a solution that contains 1.25 mol $CaCl_2$ in 1400 g of water?

41. What mass of NaCl would have to be dissolved in 1.000 kg of water to raise the boiling point by 2.00°C?

16.4 LessonCheck

42. List What are two ways of expressing the ratio of solute particles to solvent particles?

43. Explain How are freezing-point depression and boiling-point elevation related to molality?

44. Calculate How many grams of sodium bromide must be dissolved in 400.0 g of water to produce a 0.500 molal solution?

45. Calculate Calculate the mole fraction of each component in a solution of 2.50 mol ethanoic acid ($C_2H_4O_2$) in 10.00 mol of water.

46. Predict What is the freezing point of a solution of 12.0 g of CCl_4 dissolved in 750.0 g of benzene? The freezing point of benzene is 5.48°C; K_f is 5.12°C/m.

47. Make Generalizations Look at the table on page R1 of the Elements Handbook showing the distribution of elements in the oceans. What generalization can you make about the temperature at which ocean water will freeze? What effect does the presence of dissolved elements in the ocean have on the rate of evaporation of ocean water?

Lesson Check Answers

42. Molality and mole fractions are two convenient ways of expressing the ratio of solute particles to solvent particles.

43. The magnitudes of the freezing-point depression (ΔT_f) and the boiling-point elevation (ΔT_b) of a solution are directly proportional to the molal concentration (m) when the solute is molecular, not ionic.

44. 20.6 g NaBr

45. X_{CH_3COOH} = 0.200; X_{H_2O} = 0.800

46. 4.95°C

47. Given the list of dissolved elements and their concentrations in ppm, students should infer that the freezing point of ocean water is less than 0°C at 1 atm and that the rate of evaporation of ocean water is slower because of lowered vapor pressure.

Small-Scale Lab

Making a Solution

Purpose

To make a solution and use carefully measured data to calculate the solution's concentration

Materials

- solid NaCl
- water
- 50-mL volumetric flask
- balance

Procedure

Measure the mass of a clean, dry, volumetric flask. Add enough solid NaCl to fill approximately one tenth of the volume of the flask. Measure the mass of the flask again. Half fill the flask with water and shake it gently until all the NaCl dissolves. Fill the flask with water to the 50-mL mark and measure the mass again.

Analyze and Conclude

Answer the following questions based on your data.

1. Percent by mass tells how many grams of solute are present in 100 g of solution.

$$\%\text{ by mass} = \frac{\text{mass of solute}}{\text{mass of solute} + \text{solvent}} \times 100\%$$

a. Calculate the mass of the solute (NaCl).
b. Calculate the mass of the solvent (water).
c. Calculate the percent by mass of NaCl in the solution.

2. Mole fraction tells how many moles of solute are present for every 1 mol of total solution.

$$\text{Mole fraction} = \frac{\text{mol NaCl}}{\text{mol NaCl} + \text{mol } H_2O}$$

a. Calculate the moles of NaCl solute.
Molar mass of NaCl = 58.5 g/mol
b. Calculate the moles of water.
Molar mass of H_2O = 18.0 g/mol
c. Calculate the mole fraction of your solution.

3. Molality (m) tells how many moles of solute are present in 1 kg of solvent.

$$m = \frac{\text{mol NaCl}}{\text{kg } H_2O}$$

Calculate the molality of your solution.

4. Molarity (M) tells how many moles of solute are dissolved in 1 L of solution.

$$M = \frac{\text{mol NaCl}}{\text{L solution}}$$

a. Calculate the liters of solution.
b. Calculate the molarity of the NaCl solution.

5. Density tells how many grams of solution are present in 1 mL of solution.

$$\text{Density} = \frac{\text{g solution}}{\text{mL solution}}$$

Calculate the density of the solution.

You're the Chemist

The following small-scale activities allow you to develop your own procedures and analyze the results.

1. Analyze Data Measure the mass of an empty volumetric flask. Use a small-scale pipette to extract a sample of your NaCl solution and deliver it to the flask. Measure the mass of the flask again and fill it with water to the 50-mL line. Measure the mass of the flask again. Calculate the concentration of this dilute solution using the same units you used to calculate the concentration of the NaCl solution. Are the results you obtained reasonable?

2. Design an Experiment Design and carry out an experiment to make a solution of table sugar quantitatively. Calculate the concentration of the table sugar solution using the same units you used to calculate the concentration of the NaCl solution. Is the effective molality of the table sugar solution the same as the effective molality of a sodium chloride solution of the same concentration? Recall that effective molality is the concentration value used to calculate boiling-point elevation and freezing-point depression.

2. Sample data:
mass of dry flask = 16.72 g
mass of flask + sugar = 20.85 g
mass of flask + sugar + water = 69.53 g
mass of sugar = 4.13 g
mass of solvent = 48.68 g
percent mass of sugar = 7.82%
moles of sugar = 0.0121 mol
moles of water = 2.70 mol
mole fraction = 4.46×10^{-3}
molality = 0.249m
molarity = 0.242M
density = 1.1 g/mL

No, the effective molality of the NaCl solution is twice the effective molality of the sugar solution.

FOR ENRICHMENT

Students could compare the freezing point depressions of the sugar and salt solutions. (One way to do this is to partially freeze the solutions and determine the temperature of the mixtures of liquid and solid.)

Small-Scale Lab

Making a Solution

OBJECTIVE After completing this activity, students will be able to make a solution and to calculate the solution's molarity, molality, percent by mass, and mole fraction.

PREP TIME 20 minutes

CLASS TIME 20 minutes

SAFETY Wear safety goggles and a lab apron.

TEACHING TIPS Household table salt contains a small amount of desiccant, such as sodium silicate, which gives the salt solution an opaque appearance. Use lab grade NaCl instead. Remind students about significant figures. Point out that the balance is probably more accurate than the volumetric flask. Calculations based only on measurements using the balance will have a larger number of significant figures.

EXPECTED OUTCOME Students make a solution and calculate the concentration in various units.

ANALYZE AND CONCLUDE

Sample data:
dry bottle = 15.98 g
flask + NaCl = 22.88 g
flask + NaCl + water = 69.09 g

1. **a.** 6.90 g **b.** 46.21 g **c.** 13.0%
2. **a.** 0.118 mol NaCl **b.** 2.57 mol H_2O **c.** 0.0439
3. 2.55m
4. **a.** 0.050 L **b.** 2.4M
5. 1.1 g/mL

YOU'RE THE CHEMIST!

1. Sample data:
dry flask = 15.98 g
flask + NaCl solution = 22.88 g
flask + NaCl solution + water = 69.09 g
mass of NaCl solution = 2.09 g
mass of water = 47.77 g
mass of NaCl = 0.271 g
percent mass of NaCl = 0.544%
moles NaCl = 4.64×10^{-3} mol
mass of water = 49.59 g
moles of water = 2.76 mol
mole fraction = 1.68×10^{-3}
molality = 0.0936m
density = 1.0 g mL

Review and Assessment Materials

WALK-THRU TUTORIALS Each of the Sample Problems displaying the Chem Tutor icon has an online animated step-by-step tutorial that explains the problem-solving strategy in detail.

PROBLEM SETS Have students practice more chemical quantity problems by using the Chapter 16 Online Problem Set.

MATH SKILLS Have struggling students practice unit conversions by using the MathXL learning module.

VIRTUAL LABS Have students complete a virtual lab as an in-class or take-home assignment to help reinforce the concepts of vapor pressure, boiling-point elevation, and freezing-point depression.

Study Tip

Encourage students to create flashcards to help them visualize relationships and formulas. Tell them to try to integrate what they're studying with what they already know.

16 Study Guide

BIG IDEA

THE MOLE AND QUANTIFYING MATTER

Solubility, miscibility, concentration, and colligative properties are used to describe and characterize solutions. Solution concentration can be quantified in terms of molarity (moles of solute per liter of solution), molality (moles of solute per kilogram of solvent), percent by volume, and percent by mass.

16.1 Properties of Solutions

- Factors that determine how fast a substance dissolves are stirring, temperature, and surface area.
- In a saturated solution, a state of dynamic equilibrium exists between the solution and any undissolved solute, provided that the temperature remains constant.
- Temperature affects the solubility of solid, liquid, and gaseous solutes in a solvent; both temperature and pressure affect the solubility of gaseous solutes.

- saturated solution (520)
- solubility (520)
- unsaturated solution (520)
- miscible (521)
- immiscible (521)
- supersaturated solution (522)
- Henry's law (523)

Key Equation

Henry's law: $\frac{S_1}{P_1} = \frac{S_2}{P_2}$

16.2 Concentrations of Solutions

- To calculate the molarity of a solution, divide the moles of solute by the volume of the solution in liters.
- Diluting a solution reduces the number of moles of solute per unit volume, but the total number of moles of solute in solution does not change.
- Percent by volume is the ratio of the volume of solute to the volume of solution. Percent by mass is the ratio of the mass of the solute to the mass of the solution.

- concentration (525)
- dilute solution (525)
- concentrated solution (525)
- molarity (M) (525)

Key Equations

$$\text{Molarity } (M) = \frac{\text{moles of solute}}{\text{liters of solution}}$$

$$M_1 \times V_1 = M_2 \times V_2$$

$$\text{Percent by volume} = \frac{\text{volume of solute}}{\text{volume of solution}} \times 100\%$$

$$\text{Percent by mass} = \frac{\text{mass of solute}}{\text{mass of solution}} \times 100\%$$

16.3 Colligative Properties of Solutions

- Colligative properties of solutions include vapor-pressure lowering, freezing-point depression, and boiling-point elevation.

- colligative property (534)
- freezing-point depression (536)
- boiling-point elevation (537)

16.4 Calculations Involving Colligative Properties

- Chemists use two ways to express the ratio of solute to solvent: in molality and in mole fractions.
- The magnitudes of freezing-point depression and boiling-point elevation are proportional to molality.

- molality (m) (538)
- mole fraction (540)
- molal freezing-point depression constant (K_f) (542)
- molal boiling-point elevation constant (K_b) (543)

Key Equations

$$\text{Molality } (m) = \frac{\text{moles of solute}}{\text{kilogram of solvent}}$$

$$\text{Mole fractions: } X_A = \frac{n_A}{n_A + n_B} \qquad X_B = \frac{n_B}{n_A + n_B}$$

$$\Delta T_f = K_f \times m$$

$$\Delta T_b = K_b \times m$$

UbD Performance Tasks

STANDARDIZED ROAD PREP Have students research the most commonly used brine and solid road deicers used to maintain roads during winter weather events. Students should identify the chemicals used, discover the freezing-point depression provided by each chemical, and use this value to calculate the molality of the solution formed by the combination of melted precipitation and deicer.

SOLUBILITY 911 Have students determine the impact a recent well-known chemical spill has had on the environment. They should explain how emergency clean-up specialists used their knowledge of solubility to aid in the cleanup. Challenge students to create a list of emergency procedures that cleanup workers used for the chemical spill, and use solubility concepts to explain the rationale for each step.

Math Tune-Up: Solution Concentration Problems

Problem	❶ Analyze	❷ Calculate	❸ Evaluate
What volume of 12.00*M* sulfuric acid is required to prepare 1.00 L of 0.400*M* sulfuric acid?	Knowns: $M_1 = 12.00M\ H_2SO_4$ $M_2 = 0.400M\ H_2SO_4$ $V_2 = 1.00\ L$ of $0.400M\ H_2SO_4$ Unknown: $V_1 = ?\ L$ of $12.00M\ H_2SO_4$ Use the following equation to solve for the unknown initial volume of solution that is diluted: $M_1 \times V_1 = M_2 \times V_2$	Solve the equation for V_1 and substitute. $V_1 = \frac{M_2 \times V_2}{M_1}$ $V_1 = \frac{0.400\cancel{M} \times 1.00\ L}{12.00\cancel{M}}$ $V_1 = 0.0333\ L$	The concentration of the initial solution (12.00*M*) is 30 times larger than the concentration of the diluted solution (0.400*M*). So, the volume of the solution to be diluted should be one thirtieth the final volume of the diluted solution.
Ethanol is mixed with gasoline to make a solution called gasohol. What is the percent by volume of ethanol in gasohol when 95 mL of ethanol is added to sufficient gasoline to make 1.0 L of gasohol?	Knowns: volume of ethanol = 95 mL volume of solution = 1.0 L Unknown: solution concentration = ? % (v/v) Use the equation for percent by volume: $\%\ (v/v) = \frac{\text{volume of solute}}{\text{volume of solution}} \times 100\%$	Make sure the known volumes are expressed in the same units. Then calculate percent by volume of ethanol. $\%\ (v/v) = \frac{0.095\ \cancel{L}}{1.00\ \cancel{L}} \times 100\%$ $= 9.5\%\ (v/v)$	The volume of the solute is about one tenth the volume of the solution, so the answer is reasonable. The answer is correctly expressed to two significant figures.
Calculate the molality of a solution prepared by mixing 5.40 g LiBr with 444 g of water.	Knowns: mass of solute = 5.40 g mass of water = 444 g molar mass of LiBr = 86.8 g Unknown: solution concentration = ?*m* Use the equation for molal concentration: $\text{Molality} = \frac{\text{mol of solute}}{\text{kg of solvent}}$	Convert the mass of the solute to moles of solute. $5.40\ \cancel{g\ LiBr} \times \frac{1\ \text{mol LiBr}}{86.8\ \cancel{g\ LiBr}} =$ $0.0622\ \text{mol LiBr}$ Calculate molality. $\text{Molality} = \frac{0.0622\ \text{mol LiBr}}{0.444\ \text{kg}\ H_2O}$ $= 0.140m$	The answer has the correct units (mol of solute per kg of solvent) and is correctly expressed to three significant figures.

Remember: Molality is mol of solute per kg of solvent. Make sure you have the correct mass units in the denominator.

Focus on ELL

5 ASSESS UNDERSTANDING Have students complete the Standardized Test Prep for this chapter. After the results of the assessment are given, have students review the topics they do not understand.

BEGINNING: LOW/HIGH Have students underline the high-frequency words they understand and use context clues to eliminate unlikely distracters. Make sure students know how to correctly use an answer sheet.

INTERMEDIATE: LOW/HIGH Explain to students that they can skip a question that they do not understand immediately. Have students mark the question so that they remember to come back to it. Remind them to skip that answer on the answer sheet.

ADVANCED: LOW/HIGH **Ask** students to write down the questions they missed. Then, have them identify and explain why their answer was incorrect.

Math Review

Example and sample practice problems involving solutions can be found on the following pages:

LESSON 16.1 Using Henry's Law—page 524

LESSON 16.2 Calculating Molarity—page 526; Calculating the Moles of Solute in a Solution—page 527; Preparing a Dilute Solution—page 529; Calculating Percent by Volume—page 530; Using Percent by Mass as a Conversion Factor—page 531

LESSON 16.4 Use Molality—page 539; Calculating Mole Fractions—page 541; Calculating the Freezing-Point Depression of a Solution—page 543; Calculating the Boiling Point of a Solution—page 544

ASSESSMENT

Evaluate

Answers

LESSON 16.1

48. The solvent is the substance in which the solute is dissolved.

49. Random collisions of the solvent molecules with the solute particles provide enough force to overcome gravity.

50. solubility: the amount of a substance that dissolves in a given quantity of solvent at specified conditions of temperature and pressure to produce a saturated solution; saturated solution: a solution containing the maximum amount of solute for a given amount of solvent at a constant temperature and pressure; unsaturated solution: a solution that contains less solute than a saturated solution at a given temperature and pressure; miscible: describes liquids that dissolve in each other; immiscible: describes liquids that are insoluble in each other.

51. Particles of solute crystallize.

52. No; if there were undissolved solute, the excess solute would come out of a supersaturated solution.

53. 5.6×10^2 g $AgNO_3$

54. Solubility increases with pressure.

55. **a.** 1.6×10^{-2} g/L **b.** 4.7×10^{-2} g/L

LESSON 16.2

56. *Dilute* and *concentrated* are relative terms and are not quantitative. Molarity provides the exact number of moles of solute per liter of solution.

57. Molarity is the number of moles of solute dissolved in one liter of solution.
a. 1.3*M* KCl **b.** 3.3×10^{-1}*M* $MgCl_2$

58. 2.00×10^1 mL

59. 0.85*M*

60. **a.** 5.0×10^{-1} mol NaCl, 29 g NaCl
b. 1.0 mol KNO_3, 1.0×10^2 g KNO_3 c. 2.5×10^{-2} mol $CaCl_2$, 2.8 g $CaCl_2$ d. 0.60 mol Na_2SO_4, 85 g Na_2SO_4

61. **a.** 2.3×10^1 g NaCl
b. 2.0 g $MgCl_2$

62. **a.** 5.5% (m/m) **b.** 3.0% (m/m) **c.** 15% (m/m)

63. **a.** 17% (v/v) ethanol
b. 63.6% (v/v) isopropyl alcohol

LESSON 16.3

64. Colligative properties are properties of a solution that depend only on the number of solute particles; boiling-point elevation, freezing-point depression, and vapor-pressure lowering. Boiling points are elevated because solvent molecules surround solute particles, reducing the number of solvent molecules that have sufficient energy to escape the solution; relative to the pure solvent, the amount of energy required to cause vaporization or boiling increases. Solutes disrupt the ordering of the solvent structure, so more kinetic energy must be withdrawn from a solution for it to solidify. This lowers the freezing point of the solution.

65. **a.** sea water **b.** 1.5M KNO_3 **c.** 0.100M $MgCl_2$

66. The effective molality of the $Ca(NO_3)_2$ solution is 3*m*. The effective molality of the $NaNO_3$ solution is 2*m*.

67. When vapor pressure is lowered relative to pure solvent, more energy must be supplied to reach the boiling point; thus the boiling point is increased relative to pure solvent.

68. The added glucose lowers the freezing point of the solution within the frog's cells.

16 Assessment

* Solutions appear in Appendix E

Lesson by Lesson

16.1 Properties of Solutions

48. Name and distinguish between the two components of a solution.

49. Explain why the dissolved component does not settle out of a solution.

50. Define the following terms: *solubility, saturated solution, unsaturated solution, miscible,* and *immiscible.*

51. If a saturated solution of sodium nitrate is cooled, what change might you observe?

52. Can a solution with undissolved solute be supersaturated? Explain.

53. What mass of $AgNO_3$ can be dissolved in 250 g of water at 20°C? Use Table 16.1.

54. What is the effect of pressure on the solubility of gases in liquids?

***55.** The solubility of methane, the major component of natural gas, in water at 20°C and 1.00 atm pressure is 0.026 g/L. If the temperature remains constant, what will be the solubility of this gas at the following pressures?
a. 0.60 atm
b. 1.80 atm

16.2 Concentrations of Solutions

56. Knowing the molarity of a solution is more meaningful than knowing whether a solution is dilute or concentrated. Explain.

57. Define *molarity,* and then calculate the molarity of each solution.
a. 1.0 mol KCl in 750 mL of solution
b. 0.50 mol $MgCl_2$ in 1.5 L of solution

***58.** How many milliliters of 0.500*M* KCl solution would you need to dilute to make 100.0 mL of 0.100*M* KCl?

***59.** Calculate the molarity of a solution that contains 0.50 g of NaCl dissolved in 100 mL of solution.

60. Calculate the moles and grams of solute in each solution.
a. 1.0 L of 0.50*M* NaCl
b. 5.0×10^2 mL of 2.0*M* KNO_3
c. 250 mL of 0.10*M* $CaCl_2$
d. 2.0 L of 0.30*M* Na_2SO_4

***61.** Calculate the grams of solute required to make the following solutions:
a. 2500 g of saline solution (0.90% NaCl (m/m))
b. 0.050 kg of 4.0% (m/m) $MgCl_2$

62. What is the percent by mass of sodium chloride in each of the following solutions?
a. 44 g NaCl dissolved in 756 g H_2O
b. 15 g NaCl dissolved in 485 g H_2O
c. 135 g NaCl dissolved in 765 g H_2O

***63.** What is the concentration (in % (v/v)) of the following solutions?
a. 25 mL of ethanol (C_2H_6O) is diluted to a volume of 150 mL with water.
b. 175 mL of isopropyl alcohol (C_3H_8O) is diluted with water to a total volume of 275 mL.

16.3 Colligative Properties of Solutions

64. What are colligative properties? Identify three colligative properties and explain why each occurs.

65. Which has the higher boiling point:
a. seawater or distilled water?
b. 1.0*M* KNO_3 or 1.5*M* KNO_3?
c. 0.100*M* KCl or 0.100*M* $MgCl_2$?

66. Why does a 1*m* solution of calcium nitrate have a lower freezing point than a 1*m* solution of sodium nitrate?

67. Explain how a decrease in the vapor pressure of a solution results in an increase in its boiling point.

68. When the water inside a living cell freezes, the ice crystals damage the cell. The wood frog is a unique creature that can survive being frozen. In extremely cold conditions, the frog's liver produces large amounts of glucose ($C_6H_{12}O_6$), which becomes concentrated in the frog's cells. How does the glucose help prevent ice from forming in the frog's cells?

16.4 Calculations Involving Colligative Properties

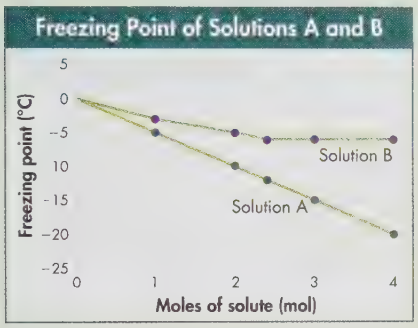
69. Distinguish between a 1*M* solution and a 1*m* solution.

70. Describe how you would make an aqueous solution of methanol (CH_4O) in which the mole fraction of methanol is 0.40.

71. What is the boiling point of each solution?

a. 0.50 mol glucose in 1000 g H_2O
b. 1.50 mol NaCl in 1000 g H_2O

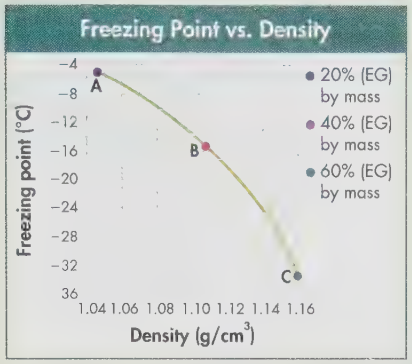
***72.** What is the freezing point of each solution?



a. 1.40 mol Na_2SO_4 in 1750 g H_2O
b. 0.060 mol $MgSO_4$ in 100 g H_2O

73. Determine the freezing points of each 0.20*m* aqueous solution.

a. K_2SO_4
b. $CsNO_3$
c. $Al(NO_3)_3$



Understand Concepts

74. Different numbers of moles of two different solutes, A and B, were added to identical quantities of water. The graph shows the freezing point of each of the solutions formed.

a. Explain the relative slopes of the two lines between 0 and 2 mol of solute added.
b. Why does the freezing point for solution A not continue to drop as amounts of solute A are added beyond 2.4 mol?

75. A mixture of ethylene glycol (EG) and water is used as antifreeze in automobile engines. The freezing point and density of the mixture vary with the percent by mass of (EG) in the mixture. On the following graph, point A represents 20% (EG) by mass; point B, 40%; and point C, 60%.

a. What is the density of the antifreeze mixture that freezes at −25°C?
b. What is the freezing point of a mixture that has a density of 1.06?
c. Estimate the freezing point of a mixture that is 30% by mass (EG).

***76.** Calculate the freezing- and boiling-point changes for a solution containing 12.0 g of naphthalene ($C_{10}H_8$) in 50.0 g of benzene.

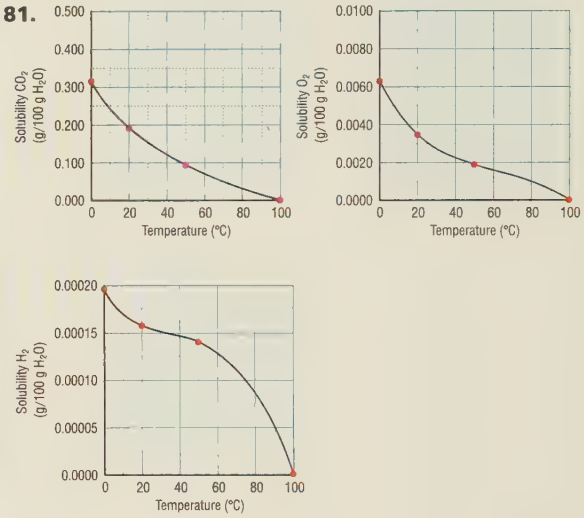
77. Describe how you would prepare an aqueous solution of acetone (C_3H_6O) in which the mole fraction of acetone is 0.25.

78. The solubility of sodium hydrogen carbonate ($NaHCO_3$) in water at 20°C is 9.6 g/100 g H_2O. What is the mole fraction of $NaHCO_3$ in a saturated solution? What is the molality of the solution?

79. A solution is labeled 0.150*m* NaCl. What are the mole fractions of the solute and solvent in this solution?

80. You are given a clear aqueous solution containing KNO_3. How would you determine experimentally if the solution is unsaturated, saturated, or supersaturated?

81. Plot a graph of solubility versus temperature for the three gases listed in Table 16.1.



ASSESSMENT

LESSON 16.4

69. 1*M* solution: 1 mol of solute in 1 L of solution; 1*m* solution: 1 mol of solute in 1000 g of solvent
70. Add 27.0 g H_2O to 32.0 g CH_4O.
71. **a.** 100.26°C **b.** 101.54°C
72. **a.** −4.46°C **b.** −2.2°C
73. **a.** −1.1°C **b.** −0.74°C **c.** −1.5°C

UNDERSTAND CONCEPTS

74. **a.** The freezing-point depression is twice as great for solute B; solute B must provide twice as many particles in solution.
b. Solute A probably forms a saturated solution.
75. **a.** about 1.14 g/cm³
b. about −7.2°C
c. about −9.5°C
76. $\Delta T_f = 9.63°C$; $\Delta T_b = 4.76°C$
77. Each gram of acetone requires 0.93 g of water.
78. The mole fraction of $NaHCO_3$ is 0.020; of water is 0.98. The solution is 1.1*m*.
79. The mole fraction of NaCl is 2.69×10^{-3}; the mole fraction of H_2O is 9.97×10^{-1}.
80. Add one crystal of KNO_3. If the solution is supersaturated, crystallization occurs. If it is saturated, the crystal does not dissolve; if unsaturated, the crystal dissolves.
81.

ASSESSMENT

Evaluate

Answers

82. fp = −1.86°C; bp = 100.512°C
83. $X_{C_2H_6O} = 0.20$; $X_{H_2O} = 0.80$
84. −0.413°C
85. **a.** 44.2 g KCl **b.** 5.8 g KCl
86. **a.** 0.30 mol **b.** 0.40 mol
c. 0.50 mol **d.** 0.20 mol

THINK CRITICALLY

87. unsaturated
88. 100.680°C
89. **a.** 7.5 g H_2O_2 **b.** 8.8×10^{-1}M
90. 5.2×10^1 g $NaNO_3$
91. 8.55×10^1 g/mol
92. $X_{H_2O} = 0.972$; $X_{C_{12}H_{22}O_{11}} = 0.028$
93. $CaCl_2$ produces three particles upon dissolving; NaCl produces only two particles. Freezing-point depression depends on the number of solute particles in the solvent.
94. chloride: 96.9 g; sodium: 54.1 g; magnesium: 6.44 g; calcium: 2.07 g; potassium: 1.99 g
95. The solution with the higher concentration of ions will have the greater boiling point elevation; 6.00 g $Ca(NO_3)_2$ in 30 g of water.
96. **a.** Solubility of each gas decreases as temperature increases.
b. 100°C
c. At higher temperatures, the gas molecules have higher kinetic energy and escape the liquid more easily.

82. Calculate the freezing point and the boiling point of a solution that contains 15.0 g of urea (CH_4N_2O) in 250 g of water. Urea is a covalently bonded compound.

83. Calculate the mole fractions in a solution that is 25.0 g of ethanol (C_2H_6O) and 40.0 g of water.

84. Estimate the freezing point of an aqueous solution of 20.0 g of glucose ($C_6H_{12}O_6$) dissolved in 500.0 g of water.

***85.** The solubility of KCl in water at 20°C is 34.0 g KCl/100 g H_2O. A warm solution containing 50.0 g KCl in 130 g H_2O is cooled to 20°C.
a. How many grams of KCl remain dissolved?
b. How many grams came out of solution?

86. How many moles of ions are present when 0.10 mol of each compound is dissolved in water?
a. K_2SO_4
b. $Fe(NO_3)_3$
c. $Al_2(SO_4)_3$
d. $NiSO_4$

Think Critically

***87. Analyze Data** A solution contains 26.5 g NaCl in 75.0 g H_2O at 20°C. Determine if the solution is unsaturated, saturated, or supersaturated. (The solubility of NaCl at 20°C is 36.0 g/100 g H_2O.)

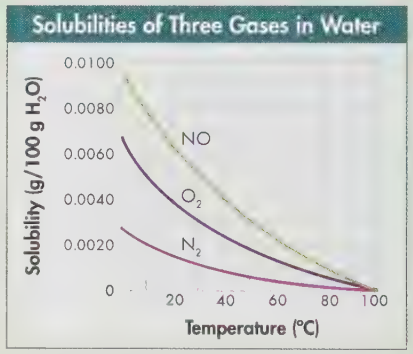
88. Infer An aqueous solution freezes at −2.47°C. What is its boiling point?

89. Calculate Percent (mass/volume), or % (m/v), is the number of grams of solute per 100 mL of solution. Hydrogen peroxide is often sold commercially as a 3.0% (m/v) aqueous solution.
a. If you buy a 250-mL bottle of 3.0% H_2O_2 (m/v), how many grams of hydrogen peroxide have you purchased?
b. What is the molarity of this solution?

90. Calculate How many grams of $NaNO_3$ will precipitate if a saturated solution of $NaNO_3$ in 200 g H_2O at 50°C is cooled to 20°C?

***91. Calculate** What is the molar mass of a nondissociating compound if 5.76 g of the compound in 750 g of benzene gives a freezing-point depression of 0.460°C?

***92. Calculate** The molality of an aqueous solution of sugar ($C_{12}H_{22}O_{11}$) is 1.62*m*. Calculate the mole fractions of sugar and water.



93. Apply Concepts Why might calcium chloride spread on icy roads be more effective at melting ice than an equal amount of sodium chloride?

94. Calculate The following table lists the molar concentrations of the most abundant monatomic ions in seawater. Calculate the mass in grams of each ion contained in 5.00 L of seawater. The density of seawater is 1.024 g/mL.

Ion	Molarity (M)
Chloride	0.546
Sodium	0.470
Magnesium	0.053
Calcium	0.0103
Potassium	0.0102

95. Compare and Contrast Which will have a greater boiling point elevation: 3.00 g $Ca(NO_3)_2$ in 60.0 g of water or 6.00 g $Ca(NO_3)_2$ in 30.0 g of water?

96. Interpret Graphs The graph shows the effect of temperature on the solubilities of oxygen gas (O_2), nitrogen gas (N_2), and nitrogen monoxide (NO) in water.

a. How does an increase in temperature affect the solubility in water of each gas?
b. At what temperature do the gases become virtually insoluble?
c. Use kinetic theory to explain the solubility behavior shown in the graph.

Enrichment

97. Calculate When an excess of zinc is added to 800 mL of a hydrochloric acid solution, the solution evolves 1.21 L of hydrogen gas measured over water at 21°C and 747.5 mm Hg. What was the molarity of the acid? The vapor pressure of water at 21°C is 18.6 mm Hg.

98. Calculate How many milliliters of 1.50*M* HNO_3 contain enough nitric acid to dissolve an old copper penny with a mass of 3.94 g?

$$3Cu + 8HNO_3 \longrightarrow 3Cu(NO_3)_2 + 2NO + 4H_2O$$

99. Graph One way to express the solubility of a compound is in terms of moles of compound that will dissolve in 1 kg of water. Solubility depends on temperature. Plot a graph of the solubility of potassium nitrate (KNO_3) from the following data:

Temperature (°C)	Solubility (mol/kg)
0	1.61
20	2.80
40	5.78
60	11.20
80	16.76
100	24.50

Using your graph, estimate

- **a.** the solubility of KNO_3 at 76°C and at 33°C.
- **b.** the temperature at which its solubility is 17.6 mol/kg of water.
- **c.** the temperature at which the solubility is 4.24 mol/kg of water.

***100. Calculate** A 250-mL sample of Na_2SO_4 is reacted with an excess of $BaCl_2$. If 5.28 g $BaSO_4$ is precipitated, what is the molarity of the Na_2SO_4 solution?

101. Design an Experiment Suppose you have an unknown compound and want to identify it by means of its molar mass. Design an experiment that uses the concept of freezing-point depression to obtain the molar mass. What laboratory measurements would you need to make? What calculations would be needed?

Write About Science

102. Describe Find a recipe for rock candy online or in a cookbook. Write a short paragraph describing how the recipe applies key concepts that you have learned about solutions. Use the terms *solute*, *solvent*, *solubility*, *crystallization*, and *supersaturated solution* in your paragraph.

***103. Sequence** Write a stepwise procedure for preparing 100 mL of 0.50*M* KCl, starting with a stock solution that is 2.0*M* KCl.

CHEMYSTERY

That Sinking Feeling

Although you can't see it happening, the groundwater beneath your feet is very slowly dissolving away rocks and minerals below ground. Eventually, enough of these mineral solutes dissolve to hollow out underground cavities or caverns. A sinkhole occurs when the roof of an underground cavern depresses or collapses.

104. Explain Why do you think areas underlain by salt beds are prone to sinkholes?

105. Infer As you read earlier in this chapter, agitation can speed up the rate at which a solid dissolves in liquid. What forces might contribute to agitating groundwater as it dissolves minerals underground?

106. Connect to the BIGIDEA Limestone, which contains mostly calcium carbonate ($CaCO_3$), is insoluble in water. Yet areas underlain by limestone are prone to sinkholes. Read the article on limestone caves on page R9. How does the "dissolving" of limestone differ from solvation?

CHEMYSTERY

START A CONVERSATION After students have read through the CHEMystery, call on volunteers to describe factors that might contribute to the formation of sinkholes and identify ways that sinkhole development might be prevented. Point out sinkholes can form for a variety of reasons. For example, sinkholes can form when the level of groundwater decreases, causing soft soil to collapse. Sinkholes might also form when fast-moving groundwater washes away underlying soil. The scenario described in the CHEMystery has another cause: groundwater dissolves minerals in the rock, leaving empty spaces that eventually collapse. **Ask** How might the rate at which groundwater moves affect the rate at which sinkholes develop? *(If sinkholes develop due to dissolving minerals, they might develop faster if the water is moving faster.)*

CHEMYSTERY ANSWERS

104. Salt beds consist of rock salt (NaCl), which is soluble in water.

105. Sample answers: gravity; earthquakes or volcanic activity; heavy precipitation or meltwater.

106. BIGIDEA Unlike solvation, which is a physical change involving a solute and solvent, the dissolving of calcium carbonate by carbonic acid is a chemical reaction.

ASSESSMENT

Answers

ENRICHMENT

97. 1.2×10^{-1}M HCl

98. 1.10×10^{2} mL HNO_3

99. a. 76°C: 15 mol/kg; 33°C: 5 mol/kg
b. 82°C **c.** 30°C

100. $9.0 \times 10^{-2}M$ Na_2SO_4

101. Determine the freezing point of a suitable solvent. Dissolve a known mass of the unknown molecular compound in a known mass of the solvent. Determine the freezing point of the solution. This gives the freezing point depression. Use $\Delta T_f = K_f \times m$ to find the molality of the solution. Use the molality to find the moles of solute. Use the moles of solute and the measured mass of solute to calculate the molar mass.

$$\frac{\text{g solute}}{\text{g solvent}} \quad \frac{\text{1000 g solvent}}{\text{1 kg solvent}} \quad \frac{\text{1 kg solvent}}{\text{1 mol solute}} = \frac{\text{g solute}}{\text{1 mol solute}}$$

The molar mass obtained is valid only for an undissociating molecular solute.

WRITE ABOUT SCIENCE

102. Answers will vary.

103. Transfer 25 mL of the stock solution to a 100-mL volumetric flask. Then add water to make 100 mL of solution.

Cumulative Review

107. **a.** 3.47×10^{-1} kg
b. 7.3 10^{-5} kg
c. 9.43×10^{-6} kg
d. 8.77×10^{-4} kg

108. 85.468 amu

109. Rutherford's model contains a nucleus.

110. **a.** manganese, Mn **b.** indium, In
c. francium, Fr **d.** polonium, Po

111. Calcium permanganate is $Ca(MnO_4)_2$. Four formula units contain 4 Ca atoms, 8 Mn atoms, and 32 O atoms.

112. **a.** :$\ddot{\underset{\cdot\cdot}{\text{I}}}$· **b.** ·$\ddot{\underset{\cdot\cdot}{\text{Te}}}$· **c.** :$\dot{\text{Sb}}$· **d.** ·Sr·

113. $C_8H_6O_4$

114. **a.** 5.58×10^1 g Fe, 6.35×10^1 g Cu, 2.01×10^2 g Hg, 3.21×10^1 g S
b. Each sample contains 6.02×10^{23} atoms.
c. 4.48×10^{-1} mol Fe, 3.94×10^{-1} mol Cu, 1.25×10^{-1} mol Hg, 7.79×10^{-1} mol S

115. 1.7×10^4 L

116. **a.** combination **b.** decomposition
c. single-replacement **d.** combustion
e. single-replacement **f.** double-replacement

117. $2H^+(aq) + S^{2-}(aq) \rightarrow H_2S(g)$

118. **a.** $NH_4Cl(s) \rightarrow NH_4^+(aq) + Cl^-(aq)$
b. $Cu(NO_3)_2(s) \rightarrow Cu^{2+}(aq) + 2NO_3^-(aq)$
c. $HNO_3(aq) \rightarrow H^+(aq) + NO_3^-(aq)$
d. $HC_2H_3O_2(l) \rightarrow H^+(aq) + C_2H_3O_2^-(aq)$
e. $Na_2SO_4(s) \rightarrow 2Na^+(aq) + SO_4^{2-}(aq)$
f. $HgCl_2(s) \rightarrow Hg^{2+}(aq) + 2Cl^-(aq)$

119. 4.9×10^1 L O_2

120. 1.08×10^2 kPa

121. The particles in an ideal gas have no volume and there are no attractions between particles.

122. Unbalanced intermolecular attractions between molecules at the surface of the liquid and those below the surface create an inward pull, or force, that minimizes the surface area to create surface tension.

123. The very polar hydrogen chloride molecule produces hydronium ions (H_3O^+) and chloride ions (Cl^-) that are stabilized by becoming surrounded by water molecules in aqueous solution. Hydrogen chloride does not dissociate in nonpolar benzene. Polar compounds generally have low solubility in nonpolar solvents.

124. a solution, if the soap mixture is very dilute; More concentrated mixtures of soap in water form colloids.

Cumulative Review

107. Convert each of the following mass measurements to its equivalent in kilograms.
a. 347 g **c.** 9.43 mg
b. 73 mg **d.** 877 mg

***108.** Rubidium has two naturally occurring isotopes. Rubidium-85 (72.165%) has a mass of 84.912 amu. Rubidium-87 (27.835%) has a mass of 86.909 amu. Calculate the average atomic mass of rubidium.

109. What is the most significant difference between the Thomson model of the atom and the Rutherford model?

110. Name and give the symbol for the element in the following positions in the periodic table:
a. Group 7B, Period 4 **c.** Group 1A, Period 7
b. Group 3A, Period 5 **d.** Group 6A, Period 6

111. How many atoms of each element are present in four formula units of calcium permanganate?

112. Draw electron dot structures for the following atoms:
a. I **b.** Te **c.** Sb **d.** Sr

113. Terephthalic acid is an organic compound used in the synthesis of polyesters. Terephthalic acid contains 57.8 percent C, 3.64 percent H, and 38.5 percent O. The molar mass is approximately 166 g/mol. What is the molecular formula of terephthalic acid?

***114.** The photograph shows one mole each of iron, copper, mercury, and sulfur.
a. What is the mass of each element?
b. How many atoms are in each sample?
c. How many moles is 25.0 g of each element?

***115.** What is the volume occupied by 1500 g of hydrogen gas (H_2) at STP?

116. Identify the type of chemical reaction.
a. $H_2(g) + Cl_2(g) \longrightarrow 2HCl(g)$
b. $2H_2O(l) \longrightarrow O_2(g) + 2H_2(g)$
c. $2K(s) + 2H_2O(l) \longrightarrow 2KOH(aq) + H_2(g)$
d. $C_2H_6O(l) + 3O_2(g) \longrightarrow 2CO_2(g) + 3H_2O(l)$
e. $Cl_2(aq) + 2KBr(aq) \longrightarrow 2KCl(aq) + Br_2(aq)$
f. $Pb(NO_3)_2(aq) + 2NaCl(aq) \longrightarrow PbCl_2(s) + 2NaNO_3(aq)$

117. Write the net ionic equation for the following reaction:

$$2HI(aq) + Na_2S(aq) \longrightarrow H_2S(g) + 2NaI(aq)$$

118. Indicate by simple equations how the following substances ionize or dissociate in water:
a. NH_4Cl **d.** $HC_2H_3O_2$
b. $Cu(NO_3)_2$ **e.** Na_2SO_4
c. HNO_3 **f.** $HgCl_2$

119. The equation for the combustion of methanol (CH_4O) is the following:

$$2CH_4O(l) + 3O_2(g) \longrightarrow 2CO_2(g) + 4H_2O(l)$$

What volume of oxygen, measured at STP, is required to completely burn 35.0 g of methanol?

***120.** A cylinder of nitrogen gas at 25°C and 101.3 kPa is heated to 45°C. What is the new pressure of the gas?

121. Why does an ideal gas not exist?

122. What relationship exists between surface tension and intermolecular attractions in a liquid?

123. The solubility of hydrogen chloride gas in the polar solvent water is much greater than its solubility in the nonpolar solvent benzene. Why?

124. When soap is shaken with water, which is formed: a solution, a suspension, or a colloid? Explain.

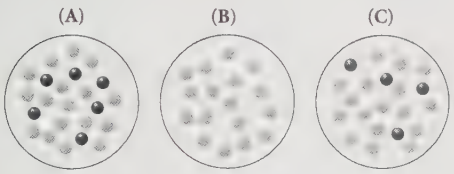
Standardized Test Prep for Indiana

Standard: C.7.2

Select the choice that best answers each question or completes each statement.

1. An aqueous solution is 65% (v/v) rubbing alcohol. How many milliliters of water are in a 95-mL sample of this solution?
   (A) 62 mL **(C)** 33 mL
   (B) 1.5 mL **(D)** 30 mL
2. When 2.0 mol of methanol is dissolved in 45 g of water, the mole fraction of methanol is
   (A) 0.44. **(C)** 2.25.
   (B) 0.043. **(D)** 0.55.



The lettered choices below refer to Questions 3–6. A lettered choice may be used once, more than once, or not at all.

(A) moles/liter of solution
(B) grams/mole
(C) moles/kilogram of solvent
(D) °C/molal
(E) no units

Which of the above units is appropriate for each measurement?

3. molality
4. mole fraction
5. molar mass
6. molarity

Use the atomic windows to answer Questions 7–9. The windows show water and two aqueous solutions with different concentrations. Black spheres represent solute particles; gray spheres represent water.

7. Which solution has the highest vapor pressure?
8. Which solution has the lowest vapor pressure?
9. Which solution has the lowest boiling point?
10. Which of these actions will cause more sugar to dissolve in a saturated sugar water solution?
    I. Add more sugar while stirring.
    II. Add more sugar and heat the solution.
    III. Grind the sugar to a powder; then add while stirring.
    (A) I only **(D)** I and II only
    (B) II only **(E)** II and III only
    (C) III only

Tips for Success

Reading Data Tables Data tables are used to summarize data. When reading a table, try to figure out the relationships between the different columns and rows of information.

Use the description and the data table to answer Questions 11–14.

A student measured the freezing points of three different aqueous solutions at five different concentrations. The data are shown below.

Molarity (*M*)	Freezing Point Depression (°C)		
	NaCl	$CaCl_2$	C_2H_6O
0.5	1.7	2.6	0.95
1.0	3.5	5.6	2.0
1.5	5.3	8.3	3.0
2.0	7.2	11.2	4.1
2.5	9.4	14.0	5.3

11. Graph the data for all three solutes on the same graph, using molarity as the independent variable.
12. Summarize the relationship between molarity and freezing-point depression.
13. Compare the slopes of the three lines and explain any difference.
14. If you collected similar data for KOH and added a fourth line to your graph, which existing line would the new line approximate?

If You Have Trouble With . . .

What's Online

CHEM TUTOR Students access guided, step-by-step tutorials for solving various thermochemistry problems.

PROBLEM SETS Students can practice key problem-solving skills in an online problems set.

MATH HELP Identify the students that struggle with math by assigning an online math skills diagnostic test. These students can then improve and practice math skills using the MathXL tutorial system.

VIRTUAL LABS Students go on animated virtual lab tours in which specific heat and heat of combustion are studied in a simulated laboratory environment.

KINETIC ART Students watch animations of selected figures from the chapter followed by questions to check for understanding.

CONCEPTS IN ACTION Students watch an overview of a key chapter concept using real-world contexts and concrete examples and analogies. Each activity includes an interactive animation followed by analysis questions.

IN ACADEMIC STANDARDS for SCIENCE

Nature of Science

- Apply standard techniques in laboratory investigations to measure physical quantities in appropriate units and convert known quantities to other units as necessary.

Thermochemistry

C.6.3 Solve problems involving heat flow and temperature changes, using known values of specific heat and/or phase change constants (latent heats).

C.6.4 Classify chemical reactions and phase changes as exothermic or endothermic.

Focus on ELL

1 CONTENT AND LANGUAGE Write the word *thermochemistry* on the board Slowly enunciate the word and have students repeat it. Point out the prefix *thermo*, means "heat." Have students use this information to predict the meaning of *thermochemistry*.

BEGINNING

LOW Have students write any unfamiliar words from the lesson titles on cards and practice saying each word.

HIGH Have students use a bilingual dictionary or glossary to find any cognates to any unfamiliar words from the lesson titles.

INTERMEDIATE: LOW/HIGH Have students use an English dictionary or the glossary to define any unfamiliar words from the lesson titles.

ADVANCED: LOW/HIGH Have students use the lesson titles to predict the purpose or main idea of the chapter.

BIG IDEA

MATTER AND ENERGY

Essential Questions:

1. *How is energy conserved in a chemical or physical process?*
2. *How can you determine the amount of energy absorbed or released in a chemical or physical process?*

CHEMYSTERY

Fighting Frost

It is a cold night in central Florida and weather forecasters are predicting that temperatures will fall to −6°C. The citrus growers in the area are in a panic. Just an hour or two of temperatures below 0°C could be devastating to the citrus trees and fruit.

Citrus growers can use a number of methods to minimize the damage to their trees and fruit in the event of a frost or freeze. Some growers install heaters to protect their crops. Other farmers use wind machines or helicopters to mix the layers of warm and cold air in the atmosphere and raise the temperature at the surface. However, one of the most common methods of protecting citrus trees is to spray water on them. The freezing of the water protects the branches, leaves, and fruit.

▶ Connect to the BIG IDEA As you read about thermochemistry, think about how water freezing can protect citrus trees from frost.

INDIANA'S ACADEMIC STANDARDS FOR SCIENCE

Thermochemistry C.6.3, C.6.4. See lessons for details.

UbD

Understanding by Design

Students are building toward describing energy changes during chemical or physical processes by using what they know about matter and energy.

PERFORMANCE GOALS At the end of Chapter 17, students will be able to answer the essential questions by applying their knowledge of thermochemistry. Students will also be able to perform calculations related to heat transfer during a reaction.

ESSENTIAL QUESTIONS Read the essential questions aloud. **Ask** What is meant by "energy is conserved" in the first question? *(Energy cannot be created or destroyed during any chemical or physical process.)* **Ask** How is it possible, then, for energy to be absorbed or released in a reaction? *(Energy can change to other forms, or it can move from one substance to another.)*

BIG IDEA Use the photo of the solar thermal power plant to help students connect to the concepts they will learn in this chapter. Activate prior knowledge by reviewing methods of energy transfer. Point out that mirrors direct the Sun's rays toward the side of the building. The rays then reflect onto collectors in the nearby tower. **Ask** What type of energy is carried by the Sun's rays? *(radiant energy)* **Ask** What happens to this energy? *(It is used as a source of heat.)*

CHEMYSTERY Have students read over the CHEMystery. Connect the CHEMystery to the Big Idea of Matter and Energy by explaining that freezing occurs because of the transfer of heat energy. Have students use this fact to predict why the growers might protect the citrus trees by spraying them with water. As a hint, remind students that a change in the state of matter involves a gain or loss of heat.

Introduce the Chapter

IDENTIFYING MISCONCEPTIONS Since students may know that some reactions reactions release heat, they may assume that other reactions release cold, rather than absorbing heat. Use the activity to identify students who may have this misconception.

Activity *You'll need two or more chemical heat packs or hand warmers, and two or more chemical cold packs.* **Ask** How does a chemical reaction affect the total energy of the reactants? *(Answers will vary. Students may say that the reactants lose energy.)* Follow the directions for activating the heat packs, and pass them around the room. **Ask** Why does the heat pack feel warm? *(Sample answer: heat is flowing from the pack to my hand.)* Follow the directions for activating the cold packs, and pass them around the room. **Ask** Why does the cold pack feel cold? *(Sample answer: cold is flowing from the pack to my hand.)* Explain that cold is not flowing from the pack to the students' hands, but that heat is flowing from their hands to the pack. Sensors in their skin detect the change in temperature, and their brains interpret this as a feeling of cold. Tell students to keep this activity in mind as they read the chapter.

LESSON 17.1

Key Objectives

17.1.1 EXPLAIN the ways in which energy changes can occur.

17.1.2 EXPLAIN how the energy of the universe before a chemical or physical process is related to the energy of the universe after a chemical or physical process.

17.1.3 IDENTIFY two factors on which the heat capacity of an object depends.

Additional Resources

Engage

CHEMISTRY & YOU **Ask** What happens to the heat in lava once it flows out of a volcano? *(The heat is released.)* **Ask** Why does lava cool more quickly in water than on land? *(Sample answer: Water has a greater capacity to absorb heat than does air; the temperature difference between the lava and water may be greater than between the lava and the air.)*

Activate Prior Knowledge

To assess whether students know the difference between temperature and energy, **Ask** What does a thermometer measure? *(average kinetic energy)* **Ask** Does a thermometer measure heat? *(no)*

IN ACADEMIC STANDARDS for SCIENCE

C.6.3 Solve problems involving heat flow and temperature changes, using known values of specific heat and/or phase change constants (latent heats).

17.1 The Flow of Energy

C.6.3 Heat flow and temperature change problems

CHEMISTRY & YOU

Q: *Why does lava cool faster in water than in air?* Lava flowing out of an erupting volcano is very hot. Its temperature ranges from 550°C to 1400°C. As lava flows down the side of a volcano, it loses heat and begins to cool slowly. In some instances, the lava may flow into the ocean, where it cools more rapidly. In this lesson, you will learn about heat flow.

Key Questions

- ***What are the ways in which energy changes can occur?***
- ***What happens to the energy of the universe during a chemical or physical process?***
- ***On what factors does the heat capacity of an object depend?***

Vocabulary

- thermochemistry
- chemical potential energy
- heat • system
- surroundings
- law of conservation of energy
- endothermic process
- exothermic process
- heat capacity
- specific heat

Energy Transformations

What are the ways in which energy changes can occur?

Energy is the capacity for doing work or supplying heat. Unlike matter, energy has neither mass nor volume. Energy is detected only because of its effects. For example, a car moves because of the energy supplied by the fuel. **Thermochemistry** is the study of energy changes that occur during chemical reactions and changes in state. Every substance has a certain amount of energy stored inside it. The energy stored in the chemical bonds of a substance is called **chemical potential energy.** The kinds of atoms and the arrangement of the atoms in a substance determine the amount of energy stored in the substance.

During a chemical reaction, a substance is transformed into another substance with a different amount of chemical potential energy. When you buy gasoline, shown in Figure 17.1, you are actually buying the stored potential energy it contains. The controlled explosions of the gasoline in a car's engine transform the potential energy into useful work, which can be used to propel the car. At the same time, however, heat is also produced, making the car's engine extremely hot. **Energy changes occur as either heat transfer or work, or a combination of both.**

Heat, represented by q, is energy that transfers from one object to another because of a temperature difference between the objects. One of the effects of adding heat to an object is an increase in its temperature. Heat flows spontaneously from a warmer object to a cooler object. If two objects remain in contact, heat will flow from the warmer object to the cooler object until the temperature of both objects is the same.

Figure 17.1 Chemical Potential Energy
Chemical potential energy is stored within the bonds of the molecules in gasoline.

Focus on ELL

1 CONTENT AND LANGUAGE Divide the class into five groups and assign each group two key vocabulary words from the lesson. Have each group pronounce the words, define the words, give a visual example of the words, and create a non-linguistic representation of the words. Have each group teach their words to the class.

2 FRONTLOAD THE LESSON Write the word *calorie* on the board. Discuss as a class the context in which students are most familiar with this word. Ask students to share three things that they have heard about calories. Explain how food calories are related to the unit of measure, calorie. Clarify any misconceptions between these two concepts.

3 COMPREHENSIBLE INPUT When discussing direction of heat flow with respect to the system, sketch the images from the various photos in the lesson on the board. Label the system and surroundings in each and draw arrows to indicate the direction of heat flow with respect to the system. Have students classify each process as endothermic or exothermic.

Endothermic and Exothermic Processes

What happens to the energy of the universe during a chemical or physical process?

Learn about temperature and heat *online.*

Chemical reactions and changes in physical state generally involve either the absorption or the release of heat. In studying energy changes, you can define a **system** as the part of the universe on which you focus your attention. Everything else in the universe makes up the **surroundings.** In thermochemical experiments, you can consider the region in the immediate vicinity of the system as the surroundings. Together, the system and its surroundings make up the universe.

A major goal of thermochemistry is to examine the flow of heat between the system and its surroundings. The **law of conservation of energy** states that in any chemical or physical process, energy is neither created nor destroyed. **During any chemical or physical process, the energy of the universe remains unchanged.** If the energy of the system increases during that process, the energy of the surroundings must decrease by the same amount. Likewise, if the energy of the system decreases during that process, the energy of the surroundings must increase by the same amount.

Direction of Heat Flow In thermochemical calculations, the direction of heat flow is given from the point of view of the system. Heat is absorbed from the surroundings in an **endothermic process.** In an endothermic process, the system gains heat as the surroundings lose heat. In Figure 17.2a, the system (the body) gains heat from its surroundings (the fire). Heat flowing into a system from its surroundings is defined as positive; q has a positive value. An **exothermic process** is one that releases heat to its surroundings. In an exothermic process, the system loses heat as the surroundings gain heat. In Figure 17.2b, the system (the body) loses heat to the surroundings (the perspiration on the skin, and the air). Heat flowing out of a system into its surroundings is defined as negative; q has a negative value.

Figure 17.2 Heat Flow
Heat flow is defined from the point of view of the system. **a.** In an endothermic process, heat flows into the system from the surroundings. **b.** In an exothermic process, heat flows from the system to the surroundings. In both cases, energy is conserved.
Apply Concepts *In which process does q have a negative value?*

Differentiated Instruction

LPR LESS PROFICIENT READERS Have students write definitions for each of the key terms in this chapter. Special attention should be given to those terms that are defined by mathematical relationships. Example calculations showing how to apply the formulas should be included in their notes.

L1 SPECIAL NEEDS STUDENTS Provide tactile examples of endothermic and exothermic reactions tailored to the main senses that the student relies on for learning.

ELL ENGLISH LANGUAGE LEARNERS Have students compare and contrast the prefixes *endo-* and *exo-*. Guide students to create symbols they can use to mark a reaction as heat absorbing or heat releasing.

Explain

Energy Transformations

USE VISUALS Direct students' attention to Figure 17.1. Have students consider the use of fuel in automobiles. **Ask** What work is done as the chemical potential energy of the fuel is released? *(The automobile moves along the road.)* **Ask** In addition to work, what other type of energy change occurs as the fuel is burned? *(heat is released)*

Exothermic and Endothermic Processes

MAKE A CONNECTION Discuss with students the distinction between kinetic and potential energy. Kinetic energy is the energy associated with an object because of its motion. Potential energy is the energy associated with an object because of its position in a field of force or due to its particular chemical composition. Explain that the potential energy of a reactant or a product in a chemical reaction is determined by the strengths of the attractive and repulsive forces between atoms. In a chemical reaction, atoms are rearranged into new groupings that have different relative potential energies. The change in potential energy is either the result of absorption of energy from the surroundings (endothermic reaction) or the release of energy to the surroundings (exothermic reaction).

Explore

Teacher Demo

PURPOSE Students will observe an endothermic reaction between two solids.

MATERIALS barium hydroxide octahydrate, ammonium chloride, 250-mL Erlenmeyer flask with stopper

SAFETY Barium salts are poisonous if ingested. Inhalation of concentrated ammonia vapors can be dangerous. Perform this demo in a fume hood or a well-ventilated room. Disposal: Flush the solution down the drain with excess water.

PROCEDURE Mix 32 g of barium hydroxide octahydrate ($Ba(OH)_2 \cdot 8H_2O$) with 11 g of ammonium chloride (NH_4Cl) in a 250-mL Erlenmeyer flask fitted with a stopper. Swirl to mix.

EXPECTED OUTCOME The flask becomes extremely cold. Place the flask on a wet piece of wood and the flask will freeze to the wood.

Answers

FIGURE 17.2b In Figure 17.2b, The system loses heat to its surroundings, so q is negative.

Explain

Endothermic and Exothermic Processes

MAKING CONNECTIONS As a class, brainstorm everyday processes students experience that absorb or release heat. Create a list on the board and randomly select students to write *–heat* or *+heat* next to each process to indicate the direction of heat flow.

Sample Practice Problem

During photosynthesis, plants use the energy from the sun to convert carbon dioxide and water into glucose and oxygen. Is photosynthesis an endothermic or exothermic process? (*endothermic*)

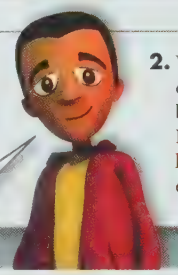
Misconception Alert

Make sure students understand the terms introduced in this section and how to convert from one to another. Students may have difficulty with the distinction between *calorie* and *Calorie* because everyday usage of the terms is often not accurate. The distinction between *heat capacity* and *specific heat* can be hard to remember because the terms are so closely related and sound so similar. Tell students to remember that *specific* heats of different materials can be compared because the quantity of matter involved (1 g) is *specified*.

SampleProblem 17.1

Recognizing Endothermic and Exothermic Processes

On a sunny winter day, the snow on a rooftop begins to melt. As the melted water drips from the roof, it refreezes into icicles. Describe the direction of heat flow as the water freezes. Is this process endothermic or exothermic?



1 Analyze **Identify the relevant concepts.** Heat flows from a warmer object to a cooler object. An endothermic process absorbs heat from the surroundings. An exothermic process releases heat to the surroundings.

2 Solve **Apply the concepts to this problem.**

First, identify the system and the surroundings.	System: water Surroundings: air
Determine the direction of heat flow.	In order for water to freeze, its temperature must decrease. Heat flows out of the water and into the air.
Determine if the process is endothermic or exothermic.	Heat is released from the system to the surroundings. The process is exothermic.

1. A container of melted wax stands at room temperature. What is the direction of heat flow as the liquid wax solidifies? Is the process endothermic or exothermic?

First, identify the system and surroundings in each situation. Then determine the direction of heat flow

2. When barium hydroxide octahydrate, $Ba(OH)_2 \cdot 8H_2O$ is mixed in a beaker with ammonium thiocyanate, NH_4SCN, a reaction occurs. The beaker becomes very cold. Is the reaction endothermic or exothermic?

Units for Measuring Heat Flow Describing the amount of heat flow requires units different than those used to describe temperature. Heat flow is measured in two common units, the calorie and the joule. You have probably heard of someone exercising to "burn calories." During exercise, your body breaks down sugars and fats in a process that releases heat. Although there is not an actual fire burning the sugars and fats within your body, chemical reactions accomplish the same result. For example, in breaking down 10 g of sugar, your body releases the same amount of heat that would be released if 10 g of sugar were completely burned in a fire.

A calorie (cal) is defined as the quantity of heat needed to raise the temperature of 1 g of pure water 1°C. The word *calorie* is written with a small *c* except when referring to the energy contained in food. The dietary Calorie, written with a capital *C*, always refers to the energy in food. One dietary Calorie is equal to one kilocalorie, or 1000 calories.

1 Calorie = 1 kilocalorie = 1000 calories

Professional Development Note

Dietary Calories

Your proper caloric intake depends on your level of physical activity. In an eight-hour day at a desk, you burn about 800 Calories. This is about the number of Calories in two helpings of spaghetti. When exercising, however, you become a relative biochemical blast furnace. In vigorous activities such as running and jumping, you expend 7–10 Calories per minute, or 420–600 Calories per hour. At these rates, a runner who covers a 26-mile marathon course in 3 hours might expend 1800 Calories, or the equivalent of 4.5 helpings of spaghetti.

The joule (J) is the SI unit of energy. One joule of heat raises the temperature of 1 g of pure water 0.2390°C. You can convert between calories and joules using the following relationships:

$$1\ J = 0.2390\ cal \qquad 4.184\ J = 1\ cal$$

Heat Capacity and Specific Heat

On what factors does the heat capacity of an object depend?

The amount of heat needed to increase the temperature of an object exactly 1°C is the **heat capacity** of that object. **The heat capacity of an object depends on both its mass and its chemical composition.** The greater the mass of the object, the greater its heat capacity. One of the massive steel cables on the bridge in Figure 17.3, for example, requires much more heat to raise its temperature 1°C than a small steel nail does.

Different substances with the same mass may have different heat capacities. On a sunny day, a 20-kg puddle of water may be cool, while a nearby 20-kg iron sewer cover may be too hot to touch. This situation illustrates how different heat capacities affect the temperature of objects. Assuming that both the water and the iron absorb the same amount of radiant energy from the sun, the temperature of the water changes less than the temperature of the iron in the same amount of time because the specific heat capacity of water is larger than the specific heat capacity of iron.

The specific heat capacity, or simply the **specific heat,** of a substance is the amount of heat it takes to raise the temperature of 1 g of the substance 1°C. Table 17.1 gives specific heats for some common substances. Water has a very high specific heat compared with the other substances in the table. Metals generally have low specific heats. The same amount of heat affects the temperature of objects of the same mass with a high specific heat much less than the temperature of those with a low specific heat.

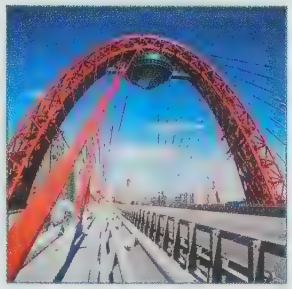


Figure 17.3 Heat Capacity
A massive steel cable has a higher heat capacity than a steel nail.

Mercury	0.14	0.033

Table 17.1 The specific heat of a substance can be expressed in J/(g·°C) or cal/(g·°C).
a. Read Tables What is the specific heat of chloroform in cal/(g·°C)?
b. Compare Which metal in the table has the highest specific heat?
c. Calculate Show how to convert the specific heat of liquid water from J/(g·°C) to cal/(g·°C).

Hint: For part c, use the relationship 1 J = 0.2390 cal to write the appropriate conversion factor.

UbD Check for Understanding

What happens to the energy of the universe during a chemical or physical process?

Access students understanding of energy flow by using the following activity. Have each student take an ice cube out of a cooler. Ask them to identify the surroundings, if the ice cube is the system. Then, have them explain the direction of energy flow that occurs as it relates to the ice cube. *(The hand is the surroundings. Energy flows from the skin to the ice cube, giving a sense that it is cold.)* **Ask** Is the process endothermic or exothermic?

ADJUST INSTRUCTION If students are having difficulty identifying the surroundings, have students reread the first paragraph of the Endothermic and Exothermic Processes section. Then, ask students where the heat transfer occurs between the skin and the ice cube. *(The transfer is occurring between the surface molecules of the skin and the surface molecules of the ice.)* Explain that the process is endothermic because the ice gains heat from the hand.

Explain

Heat Capacity and Specific Heat

USE VISUALS Have students study Table 17.1. **Ask** Which has a higher specific heat capacity—water or steam? *(water)* **Ask** What factors do you think affect the specific heat of each substance? *(Specific heat is affected by the amount of heat and the change in temperature.)*

Explore

Class Activity

PURPOSE Students will compare heat transfer of different materials.

MATERIALS sheet metal (13 cm × 18 cm), foam (13 cm × 18 cm), wood (40 cm × 20 cm), glue

PROCEDURE Glue a 13 cm × 18 cm piece of sheet metal and a 13 cm × 18 cm piece of foam to a piece of wood that is about 40 cm × 20 cm. Pass the wood around the classroom, and ask students to put their hands on each of the three surfaces and describe the temperature of each.

EXPECTED OUTCOME Usually students indicate that the metal feels the coldest and the foam feels the same temperature as their hands. Explain that all of the surfaces are colder than their hand, and that heat is being transferred from their hand to those surfaces. Convey that metals conduct heat away from the hand more efficiently than foam, so they feel colder than foam.

Answers

1. Heat flows from the system (wax) to the surroundings (air). The process is exothermic.
2. Since the beaker becomes cold, heat is absorbed by the system (chemicals within the beaker) from the surroundings (beaker and surrounding air). The process is endothermic.

c. $4.18\ J/(g \cdot °C) \times \frac{0.2390\ cal}{1\ J} = 1.00\ cal/(g \cdot °C)$

Explain

CRITICAL THINKING Direct students to Figure 17.4 and discuss the difference in temperature between a coastal city such as San Francisco and an inland city such as Fresno. State the following a remark once made by Mark Twain: "The coldest winter I ever spent was the summer I spent in San Francisco." **Ask** How does this quote relate to the temperature difference between a coastal city and an inland city? *(The relatively high heat capacity of the large bodies of water near San Francisco help to moderate local temperatures. During summer, the ocean water warms slowly as it absorbs large amounts of heat from warm air masses. Onshore breezes off the cool water keep coastal land temperatures from rising to match those of inland areas. Condensation of water vapor in the air produces a cool fog, which probably enhanced Mark Twain's impression of the cool of San Francisco summers.)*

CHEMISTRY & YOU A given mass of water can absorb more heat from the lava than an equal mass of air.

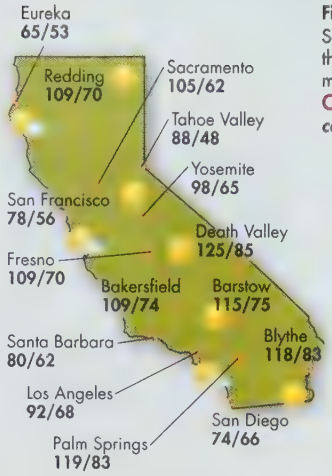

Figure 17.4 Temperature Moderation
San Francisco is located on the Pacific coast. The high specific heat of the water in the ocean helps keep the temperature in San Francisco much more moderate than that of the towns and cities farther inland.
Compare ***Describe how the ocean affects the temperature of coastal areas in the summer and in the winter.***

Specific Heat of Water Just as it takes a lot of heat to raise the temperature of water, water also releases a lot of heat as it cools. Water in lakes and oceans absorbs heat from the air on hot days and releases it back into the air on cool days. As illustrated in Figure 17.4, this property of water is responsible for moderate climates in coastal areas. Citrus farmers often spray their trees with water to protect the fruit from frost damage during icy weather. As the water freezes, it releases heat, which helps prevent the fruit from freezing. When a freshly baked apple pie, such as the one shown in Figure 17.5, comes out of the oven, both the filling and crust are at the same temperature. However, the filling, which is mostly water, has a higher specific heat than the crust. In order to cool down, the filling must give off a lot of heat. This release of heat is why you have to be careful not to burn your tongue when eating hot apple pie.

Calculating Specific Heat To calculate the specific heat (C) of a substance, you divide the heat input by the mass of the substance times the temperature change.

$$C = \frac{q}{m \times \Delta T} = \frac{\text{heat (J or cal)}}{\text{mass (g)} \times \text{change in temperature (°C)}}$$

In the equation above, q is heat and m is mass. The symbol ΔT (read "delta T") represents the change in temperature. ΔT is calculated from the equation $\Delta T = T_f - T_i$, where T_f is the final temperature and T_i is the initial temperature. As you can see from the equation and in Table 17.1 on the previous page, heat may be expressed in terms of joules or calories. Therefore, the units of specific heat are either J/(g·°C) or cal/(g·°C).

CHEMISTRY & YOU

Q: *Heat will flow from the lava to the surroundings until the lava and surroundings are at the same temperature. Air has a smaller specific heat than water. Why would lava then cool more quickly in water than in air?*

Figure 17.5 Cooling of Water
The filling of a hot apple pie is mostly water, so it is much more likely to burn your tongue than the crust.

Foundations for Math

SYMBOLS Students often struggle with calculations involving the delta (Δ) symbol, as some calculations require the subtraction of the smallest value from the largest, while in others the initial value is subtracted from the final value. Explain that in specific heat calculations, the presence of Δ in the denominator of the equation indicates that the initial temperature should be subtracted from the final temperature.

In **Sample Problem 17.2,** the initial temperature is 25°C and the final temperature is 48.0°C. Explain to students that they can verify that their order is correct by looking for words that indicate the direction of change, such as *increase* and *decrease*. In this problem, the phrase *increases from 25.0°C* provides additional evidence that the lower value is is the initial value.

Sample Problem 17.2

Calculating the Specific Heat of a Substance

The temperature of a 95.4-g piece of copper increases from 25.0°C to 48.0°C when the copper absorbs 849 J of heat. What is the specific heat of copper?

KNOWNS

$m_{Cu} = 95.4\ g$

$\Delta T = 48.0°C - 25.0°C = 23.0°C$

$q = 849\ J$

UNKNOWN

$C_{Cu} = ?\ J/(g \cdot °C)$

1 Analyze **List the knowns and the unknown.** Use the known values and the definition of specific heat.

2 Calculate **Solve for the unknown.**

Start with the equation for specific heat.

$$C_{Cu} = \frac{q}{m_{Cu} \times \Delta T}$$

Substitute the known quantities into the equation to calculate the unknown value C_{Cu}.

$$C_{Cu} = \frac{849\ J}{95.4\ g \times 23.0°C} = 0.387\ J/(g \cdot °C)$$

3 Evaluate **Does the result make sense?** Remember that liquid water has a specific heat of 4.18 J/(g·°C). Metals have specific heats lower than water. Thus the calculated value of 0.387 J/(g·°C) seems reasonable.

3. When 435 J of heat is added to 3.4 g of olive oil at 21°C, the temperature increases to 85°C. What is the specific heat of the olive oil?

4. How much heat is required to raise the temperature of 250.0 g of mercury 52°C?

You can find the specific heat of mercury on Table 17.1.

5. Review What are the ways that energy conversion can occur?

6. Describe What happens to the energy of the universe during a physical or chemical process?

7. List On what two factors does the heat capacity of an object depend?

8. Classify On a cold night you use an electric blanket to warm your body. Describe the direction of heat flow. Is this process endothermic or exothermic?

9. Calculate A chunk of silver has a heat capacity of 42.8 J/°C and a mass of 181 g. Calculate the specific heat of silver.

10. Calculate Using calories, calculate how much heat 32.0 g of water absorbs when it is heated from 25.0°C to 80.0°C. How many joules is this?

BIG IDEA MATTER AND ENERGY

11. How is the energy of the universe conserved during the combustion of gasoline in a car engine?

Lesson Check Answers

5. Energy changes occur as either heat transfer or work, or a combination of both.

6. The energy of the universe remains unchanged.

7. mass and chemical composition

8. Heat flows from the blanket to your body. If you body is the system, the process is endothermic.

9. 2.36×10^{-1} J/(g · °C)

10. 1.76×10^{3} cal (1.76 kcal); 7.36×10^{3} J (7.36 kJ)

11. Chemical energy in the gasoline is transformed into energy to move the car. None of the energy is lost in the process.

Sample Practice Problem

How much heat is required to raise the temperature of 3.5 g of grain alcohol 15°C? *(1.26×10^2 J)*

Evaluate

Informal Assessment

Place an ice cube in a beaker of cool water. Have students discuss the flow of heat when the ice and water are the system and surroundings, respectively, and when the ice/water mixture and a 37°C room are the system and surroundings, respectively. Then have students complete the 17.1 Lesson Check.

Reteach

Emphasize that substances vary in their response to an input of heat; a given amount of heat raises the temperature of some substances (such as metals) far more than others (such as nonmetals). Point out that specific heat is a property of a substance; it is a measure of the ability of a substance to store heat.

Answers

3. 2.0 J/(g · °C)

4. 1.8 kJ

Engage

CHEMISTRY & YOU Tell students that a match will not ignite unless you strike it and add heat to it. **Ask** Where does the heat that is added to the match come from? *(friction)* **Ask** Is the burning of a match an endothermic reaction? Explain. *(No; the reaction releases more energy, in the form of heat and light, than the amount it absorbs to start.)*

Build Background

Ask students to predict whether there is a way to measure how much heat is released from a burning match. *(Answers will vary.)* Explain that it is possible, but only indirectly. If the reaction were confined, then any temperature changes in the surroundings could be attributed to heat transfer from the reaction. Tell students to keep this in mind as they proceed with the lesson.

IN ACADEMIC STANDARDS for SCIENCE

C.6.3 Solve problems involving heat flow and temperature changes, using known values of specific heat and/or phase change constants (latent heats).

C.6.4 Classify chemical reactions and phase changes as exothermic or endothermic.

17.2 Measuring and Expressing Enthalpy Changes

C.6.3 Heat flow and temperature change problems, C.6.4 Exothermic and endothermic reactions

CHEMISTRY & YOU

Q: *How can you measure the amount of heat released when a match burns?* When you strike a match, heat is released to the surroundings. In addition to describing the direction of heat flow, you may also want to determine the quantity of heat that is transferred. The concept of specific heat allows you to measure heat flow in chemical and physical processes.

Key Questions

How can you measure the change in enthalpy of a reaction?

How can you express the enthalpy change for a reaction in a chemical equation?

Vocabulary

- calorimetry
- calorimeter
- enthalpy
- thermochemical equation
- heat of reaction
- heat of combustion

Calorimetry

How can you measure the change in enthalpy of a reaction?

Heat that is absorbed or released during many chemical reactions can be measured by a technique called calorimetry. **Calorimetry** is the measurement of the heat flow into or out of a system for chemical and physical processes. In a calorimetry experiment involving an endothermic process, the heat absorbed by the system is equal to the heat released by its surroundings. In an exothermic process, the heat released by a system is equal to the heat absorbed by its surroundings. The insulated device used to measure the absorption or release of heat in chemical or physical processes is called a **calorimeter.**

Constant-Pressure Calorimeters Foam cups can be used as simple calorimeters because they do not let much heat in or out. The heat flows for many chemical reactions can be measured in a constant-pressure calorimeter similar to the one shown in Figure 17.6. Most chemical reactions and physical changes carried out in the laboratory are open to the atmosphere and, thus, occur at constant pressure. The **enthalpy** (H) of a system accounts for the heat flow of the system at constant pressure.

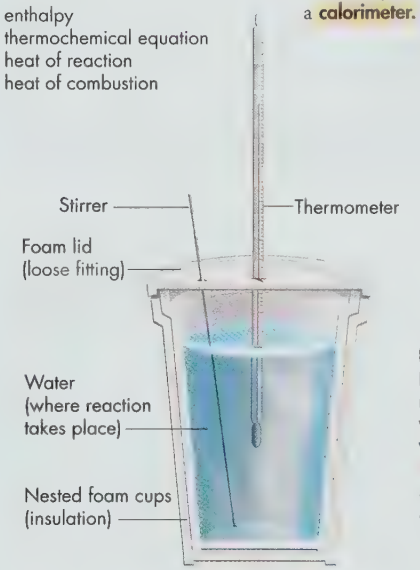

Figure 17.6 Constant-Pressure Calorimeter
In a simple constant-pressure calorimeter, a thermometer records the temperature change as chemicals react in water. The reacting substances constitute the system. The water constitutes the surroundings.
Relate Cause and Effect ***What happens to the temperature of the water if heat is released by the reaction in the calorimeter?***

Focus on ELL

1 CONTENT AND LANGUAGE Discuss the meaning of the suffixes *–metry* and *–meter* and how to use suffixes to determine the meaning of words. Then ask students to predict the meaning of the words *calorimetry* and *calorimeter*.

2 FRONTLOAD THE LESSON Have students brainstorm enthalpy changes that occur in their daily lives. Ask them to consider how these changes can be measured. *(Sample answer: a change in temperature)* **Ask** How could you make sure you are measuring and identifying only the enthalpy change in the system you are studying? Explain that, in this lesson, they will learn the answer to this question.

3 COMPREHENSIBLE INPUT When explaining the signs of enthalpy changes in endothermic and exothermic reactions, make the connection between a + sign, addition of energy to the system, and the meaning of the prefix *endo-*. Make a similar connection between a – sign, release (subtraction) of energy from the system, and the meaning of the prefix *exo-*.

The heat absorbed or released by a reaction at constant pressure is the same as the change in enthalpy, symbolized as ΔH. **The value of ΔH of a reaction can be determined by measuring the heat flow of the reaction at constant pressure.** In this textbook, the terms *heat* and *enthalpy change* are used interchangeably because the reactions presented occur at constant pressure. In other words, $q = \Delta H$.

To measure the enthalpy change for a reaction in aqueous solution in a foam cup calorimeter, dissolve the reacting chemicals (the system) in known volumes of water (the surroundings). Measure the initial temperature of each solution, and mix the solutions in the foam cup. After the reaction is complete, measure the final temperature of the mixed solutions. You can calculate the heat absorbed or released by the surroundings (q_{surr}) using the formula for specific heat, the initial and final temperatures, and the heat capacity of water.

$$q_{surr} = m \times C \times \Delta T$$

In this expression, m is the mass of the water, C is the specific heat of water, and $\Delta T = T_f - T_i$. The heat absorbed by the surroundings is equal to, but has the opposite sign of, the heat released by the system. Conversely, the heat released by the surroundings is equal to, but has the opposite sign of, the heat absorbed by the system. Therefore, the enthalpy change for the reaction (ΔH) can be written as follows:

$$q_{sys} = \Delta H = -q_{surr} = -m \times C \times \Delta T$$

The sign of ΔH is positive for an endothermic reaction and negative for an exothermic reaction.

Constant-Volume Calorimeters Calorimetry experiments can also be performed at constant volume using a device called a bomb calorimeter. In a bomb calorimeter, which is shown in Figure 17.7, a sample of a compound is burned in a constant-volume chamber in the presence of oxygen at high pressure. The heat that is released warms the water surrounding the chamber. By measuring the temperature increase of the water, it is possible to calculate the quantity of heat released during the combustion reaction.

CHEMISTRY & YOU

Q: *What type of calorimeter would you use to measure the heat released when a match burns? Describe the experiment and how you would calculate the heat released.*

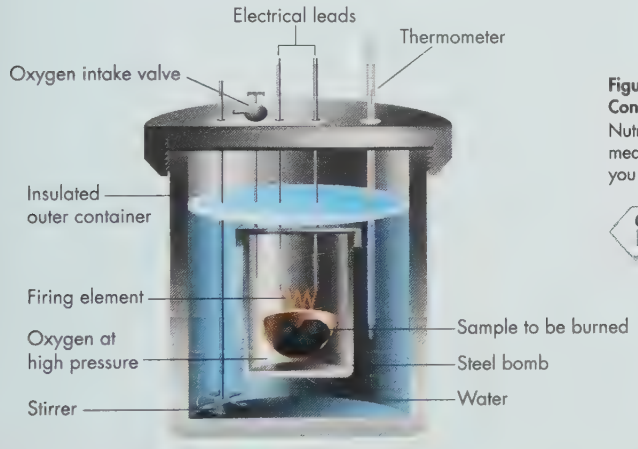

Figure 17.7
Constant-Volume Calorimeter
Nutritionists use bomb calorimeters to measure the energy content of the foods you eat.

Go online to see how a bomb calorimeter is used.

UbD Check for Understanding

How is energy conserved in a chemical or physical process?

Assess students' understanding of this Essential Question by having them write a one-minute explanation of how the relationship between q_{sys} and q_{surr} in a calorimetric experiment proves the law of conservation of energy.

ADJUST INSTRUCTION If students have difficulty writing an explanation, have students reread the text in the Constant-Pressure Calorimeters section. Then, review the specific heat equations given in the text with students. Allow students an opportunity to revise their explanations following this review.

Explain

Calorimetry

CHEMISTRY & YOU You would use a constant-volume calorimeter. You would burn the match in a steel bomb. Then you would measure the temperature increase of the surrounding water. Finally, you multiply the mass of water, by the specific heat of water, by the temperature change of water and you get the heat released by the match.

Explore

Class Activity

PURPOSE Students will make calorimetry measurements and calculations. Two separate but related oxidation-reduction reactions will be studied by different groups of students. The results can then be pooled and compared to provide insight into how calorimetry can be used as a tool to investigate the physical and chemical properties of substances.

MATERIALS 1*M* HCl, foam cup, thermometer, mossy zinc, magnesium turnings

SAFETY Students must wear protective goggles and aprons. Remind them of the safety precautions needed for handling HCl. Use a fume hood if possible. Students should not be allowed to dispense concentrated HCl themselves.

PROCEDURE Pour 100 mL of 1*M* HCl into a foam cup and determine the temperature to the nearest tenth of a degree Celsius. Add 0.5 g of mossy zinc or 0.5 g of magnesium turnings.

EXPECTED OUTCOME For calculations, ignore the mass of the solids added. Assume that HCl is primarily water and has the same specific heat and density of water.

$\Delta H = 100\ g \times 4.18\ J/(g \cdot °C) \times \Delta T$

ΔH_{rxn} Zn = –150 kJ/mol

ΔH_{rxn} Mg = –460 kJ/mol

Discuss sources of error such as heat lost to surroundings.

Answers

FIGURE 17.6 The temperature of the water increases.

Explain

Calorimeters

MAKING CONNECTIONS Display photographs or actual examples of the types of calorimeter(s) used in laboratories today. Discuss the use of calorimetry as an analytical tool; for example, in investigating the caloric content of foods.

Misconception Alert

Make sure students understand all the terms in the equation $q_{sys} = \Delta H = -m \times C \times \Delta T$. Emphasize that the delta notation (Δ) represents an algebraic operation involving two separate measurements. Explain that when determining the algebraic value of ΔT, the algebraic signs of the *final* and *initial* temperatures must be included in the operation.

Sample Practice Problem

A copper coin is heated and placed in a foam cup calorimeter containing 32.0 mL of water at 22.0°C. The water reaches a temperature of 24.0°C. How many joules of heat were released by the coin? *(268 J)*

Extend

Connect to ENVIRONMENTAL SCIENCE

Tell students that a large percentage of the electricity used in the United States is produced by the burning of fossil fuels. Explain that power plants generate electricity by transferring heat to water during the combustion of fossil fuels; the heated water turns to steam, which drives turbines that generate electricity. Explain that in order to condense and recycle the steam, a source of coolant water is needed, consequently, power plants (including nuclear power plants) are often built near a source of water, such as an ocean, lake, or river. However, when the coolant water is returned to its source, it is usually warmer. Explain that this increase in temperature is called thermal pollution. Have students research this topic and then conduct a class debate to determine if this label is justified.

Sample Problem 17.3

Enthalpy Change in a Calorimetry Experiment

When 25.0 mL of water containing 0.025 mol HCl at 25.0°C is added to 25.0 mL of water containing 0.025 mol NaOH at 25.0°C in a foam cup calorimeter, a reaction occurs. Calculate the enthalpy change (in kJ) during this reaction if the highest temperature observed is 32.0°C. Assume the densities of the solutions are 1.00 g/mL and that the volume of the final solution is equal to the sum of the volumes of the reacting solutions.

1 Analyze **List the knowns and the unknown.**
Use dimensional analysis to determine the mass of the water. You must also calculate ΔT. Use $\Delta H = -q_{surr} = -m \times C \times \Delta T$ to solve for ΔH.

KNOWNS
$C_{water} = 4.18\ J/(g \cdot °C)$
$V_{final} = V_{HCl} + V_{NaOH}$
$= 25.0\ mL + 25.0\ mL = 50.0\ mL$
$T_i = 25.0°C$
$T_f = 32.0°C$
$density_{solution} = 1.00\ g/mL$

UNKNOWN
$\Delta H = ?\ kJ$

2 Calculate **Solve for the unknown.**

First, calculate the total mass of the water.

$$m_{water} = 50.0\ \cancel{mL} \times \frac{1.00\ g}{1\ \cancel{mL}} = 50.0\ g$$

Now, calculate ΔT.

$$\Delta T = T_f - T_i = 32.0°C - 25.0°C = 7.0°C$$

Use the values for m_{water}, C_{water}, and ΔT to calculate ΔH.

$$\Delta H = -q_{surr} = -m_{water} \times C_{water} \times \Delta T$$
$$= -(50.0\ g)(4.18\ J/(g \cdot °C))(7.0°C)$$
$$= -1500\ J = -1.5\ kJ$$

Use the relationship 1 kJ = 1000 J to convert your answer from J to kJ.

3 Evaluate **Does the result make sense?** The temperature of the solution increases, which means that the reaction is exothermic, and thus the sign of ΔH should be negative. About 4 J of heat raises the temperature of 1 g of water 1°C, so 200 J of heat is required to raise 50 g of water 1°C. Raising the temperature of 50 g of water 7°C requires about 1400 J, or 1.4 kJ. This estimated answer is very close to the calculated value of ΔH.

12. When 50.0 mL of water containing 0.50 mol HCl at 22.5°C is mixed with 50.0 mL of water containing 0.50 mol NaOH at 22.5°C in a calorimeter, the temperature of the solution increases to 26.0°C. How much heat (in kJ) is released by this reaction?

Assume that the densities of the solutions are 1.00 g/mL to find the total mass of the water.

13. A small pebble is heated and placed in a foam cup calorimeter containing 25.0 mL of water at 25.0°C. The water reaches a maximum temperature of 26.4°C. How many joules of heat are released by the pebble?

Foundations for Math

MULTI-STEP PROBLEMS Although the equation for calculating ΔH is straightforward, more than one step may be necessary before this calculation can be successfully completed. This occurs when the quantity of substance is given as a volume or a molar quantity, or when the value of ΔT must be calculated.

In **Sample Problem 17.3,** the system is comprised of equal volumes of HCl and NaOH solutions, which must be converted to mass in grams. Since the reaction is a neutralization reaction between a strong acid and a strong base, you can assume that the density of the solution is approximately equal to the density of water. Once the mass of the solution and the temperature change are determined, the values can be plugged into the equation as the final step.

Thermochemical Equations

How can you express the enthalpy change for a reaction in a chemical equation?

If you mix calcium oxide with water, the water in the mixture becomes warm. This exothermic reaction occurs when cement, which contains calcium oxide, is mixed with water to make concrete. When 1 mol of calcium oxide reacts with 1 mol of water, 1 mol of calcium hydroxide forms and 65.2 kJ of heat is released. **In a chemical equation, the enthalpy change for the reaction can be written as either a reactant or a product.** In the equation describing the exothermic reaction of calcium oxide and water, the enthalpy change can be considered a product.

$$CaO(s) + H_2O(l) \longrightarrow Ca(OH)_2(s) + 65.2\ kJ$$

This equation is presented visually in Figure 17.8. A chemical equation that includes the enthalpy change is called a **thermochemical equation.**

Heats of Reaction The **heat of reaction** is the enthalpy change for the chemical equation exactly as it is written. You will usually see heats of reaction reported as ΔH, which is equal to the heat flow at constant pressure. The physical state of the reactants and products must also be given. The standard conditions are that the reaction is carried out at 101.3 kPa (1 atm) and that the reactants and products are in their usual physical states at 25°C. The heat of reaction, or ΔH, in the above example is −65.2 kJ. Each mole of calcium oxide and water that reacts to form calcium hydroxide produces 65.2 kJ of heat.

$$CaO(s) + H_2O(l) \longrightarrow Ca(OH)_2(s) \qquad \Delta H = -65.2\ kJ$$

In this and other exothermic processes, the chemical potential energy of the reactants is higher than the chemical potential energy of the products.

READING SUPPORT

Build Comprehension: ***Use Prior Knowledge*** Thermochemical equations are just like other balanced equations. If heat is absorbed in the reaction, it is written as a reactant. If heat is released, it is written as a product. ***Recall chemical reactions from Chapter 11. For the combustion of methane, on which side of the reaction arrow would you write the heat absorbed or released by the reaction?***

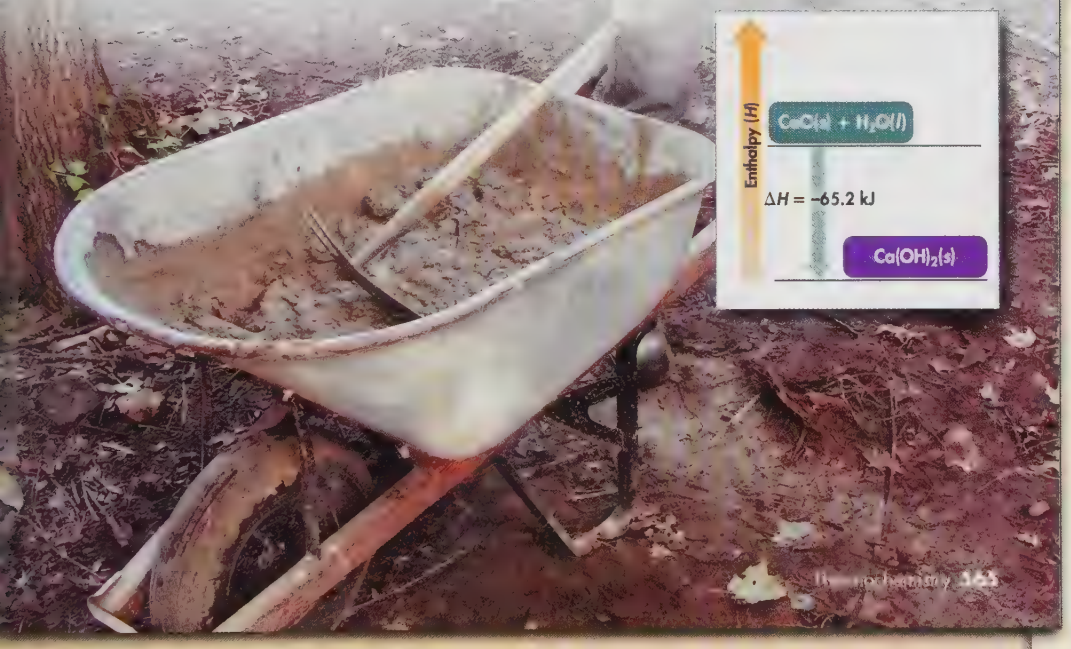

Figure 17.8 Exothermic Process Calcium oxide is one of the components of cement. The reaction of calcium oxide and water is an exothermic process.

Differentiated Instruction

L1 SPECIAL NEED STUDENTS Have students Iron wool burns rapidly in high concentrations of oxygen it oxidizes slowly at the concentrations found in air. Rusting of iron is essentially a slow combustion reaction. Demonstrate that the reaction is exothermic by wrapping moist iron wool around the bulb of a thermometer. Have students work in small groups to quantify the thermodynamic parameters of the reaction by using a foam cup calorimeter.

LPR LESS PROFICIENT READERS Special attention should be given to vocabulary terms in the chapter that are defined by mathematical relationships. Have students write definitions of these terms. Sample calculations showing how to apply the formulas should be included in students' notes.

Explain

Thermochemical Equations

APPLY CONCEPTS To illustrate writing a thermochemical equation, refer to two familiar reactions. Show students that the combustion of methane in a Bunsen burner adds energy to the surroundings, thus, the burning of methane has a negative ΔH.

$$CH_4(g) + 2O_2(g) \rightarrow CO_2(g) + 2H_2O(g) + 890\ kJ$$
$$\Delta H = -890\ kJ/mol$$

Explain that during the electrolysis of water, electrical energy is used to decompose the water into hydrogen gas and oxygen gas. Point out that energy is added to the system from the surroundings. Thus, the electrolysis of water has a positive ΔH.

$$241.8\ kJ + 2H_2O(l) \rightarrow 2H_2(g) + O_2(g)$$
$$\Delta H = +241.8\ kJ/mol$$

Misconception Alert

Remind students that the sign of ΔH indicates whether the reaction is endothermic (+) or exothermic (–). Although an exothermic reaction has a negative ΔH by convention, heat is expressed as an absolute value when it is shown as a "product" in an equation.

USE VISUALS Have students examine Figure 17.8. Instruct students to draw similar diagrams for the burning of CH_4 and the electrolysis of H_2O. For each reaction, **Ask** Is the potential energy of the reactants higher or lower than the products? *(higher for CH_4, lower for H_2O)* **Ask** In what direction does heat move in the CaO reaction? *(into the surroundings)* **Ask** In what direction does heat move in the $NaHCO_3$ reaction? *(absorbed from the surroundings by the reaction)*

Answers

12. −1.46 kJ

13. −150 J

READING SUPPORT Heat is released so you write it on the right side of the equation.

Explain

MAKE A CONNECTION Tell interested students that the decomposition of sodium bicarbonate to form carbon dioxide gas is essential for successful baking. Sodium bicarbonate, also called baking soda, is the source of the carbon dioxide that causes cakes, muffins, and quick breads to rise in the oven. **Ask** What is the result if you forget to add this ingredient to a cookie recipe? *(Without baking soda, the result is a flat and heavy, and not very tasty cookie.)*

Explore

An Exothermic Reaction

Teacher Demo

PURPOSE Students will observe an exothermic reaction and write a thermochemical equation.

MATERIALS CaO, metal tray, thin aluminum pan, water, egg (raw)

SAFETY CaO is corrosive.

PROCEDURE Place 100 g of CaO in a metal tray. Place a thin aluminum pan or pie tin in the tray so that its bottom is completely in contact with the calcium oxide. Pour just enough water into the tray to cover the calcium oxide. Then break a fresh egg into the aluminum pan. **Ask** Is this an exothermic or endothermic reaction? *(Exothermic; 65.2 kJ of heat is released per mole of CaO.)* Have students write a thermochemical equation to describe the reaction. Check to see that students express the enthalpy of reaction as a negative value. Have students use the thermochemical equation to answer stoichiometric questions such as: How much heat is released when 100.0 g of calcium oxide reacts with excess water? *(116 kJ)*

EXPECTED OUTCOME Students should observe that enough heat is liberated by the reaction to cook the egg.

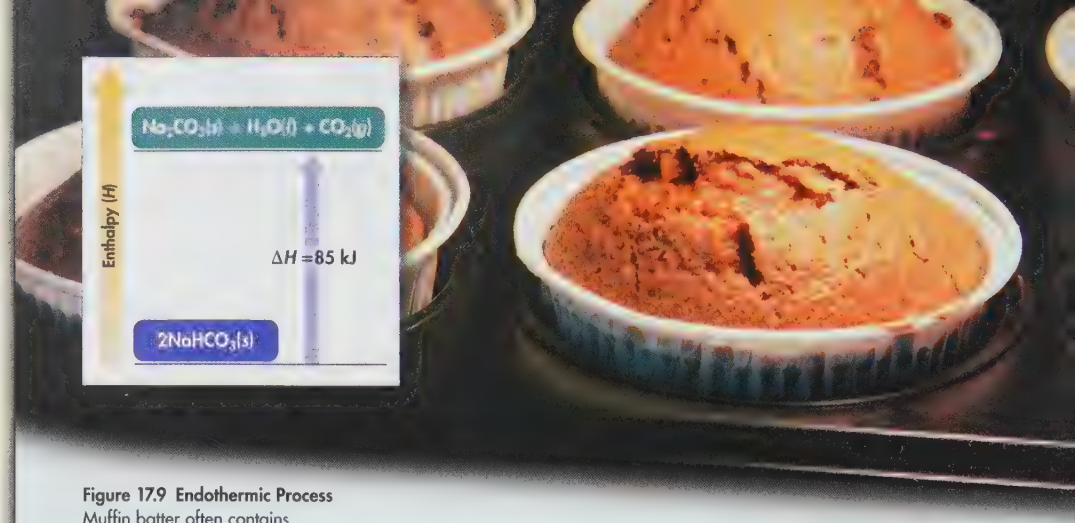

Figure 17.9 Endothermic Process Muffin batter often contains baking soda, also known as sodium bicarbonate. The decomposition of sodium bicarbonate is an endothermic process.

Other reactions absorb heat from the surroundings. For example, baking soda (sodium bicarbonate) decomposes when it is heated. The carbon dioxide released in the reaction causes muffins to rise while baking. This process is endothermic.

$$2NaHCO_3(s) + 85\ kJ \longrightarrow Na_2CO_3(s) + H_2O(l) + CO_2(g)$$

Remember that ΔH is positive for endothermic reactions. Therefore, you can write the reaction as follows:

$$2NaHCO_3(s) \longrightarrow Na_2CO_3(s) + H_2O(l) + CO_2(g) \qquad \Delta H = 85\ kJ$$

Figure 17.9 shows the enthalpy diagram for this reaction.

Chemistry problems involving enthalpy changes are similar to stoichiometry problems. The amount of heat released or absorbed during a reaction depends on the number of moles of the reactants involved. The decomposition of 2 mol of sodium bicarbonate, for example, requires 85 kJ of heat. Therefore, the decomposition of 4 mol of the same substance would require twice as much heat, or 170 kJ. In this and other endothermic processes, the chemical potential energy of the products is higher than the chemical potential energy of the reactants.

To see why the physical state of the reactants and products in a thermochemical reaction must be stated, compare the following two equations for the decomposition of 1 mol H_2O:

$$H_2O(l) \longrightarrow H_2(g) + \tfrac{1}{2}O_2(g) \qquad \Delta H = 285.8\ kJ$$
$$H_2O(g) \longrightarrow H_2(g) + \tfrac{1}{2}O_2(g) \qquad \Delta H = 241.8\ kJ$$
$$\text{difference} = 44.0\ kJ$$

Although the two equations are very similar, the different physical states of H_2O result in different ΔH values. In one case, the reactant is a liquid; in the other case, the reactant is a gas. The vaporization of 1 mol of liquid water to water vapor at 25°C requires 44.0 kJ of heat.

$$H_2O(l) \longrightarrow H_2O(g) \qquad \Delta H = 44.0\ kJ$$

Professional Development Note

Keeping Warm

How do animals such as polar bears and seals survive the cold land and water temperatures where they live? A good coat of fur helps, but it is not enough to keep them warm. These animals also have unique fat cells that help generate heat. These fat cells are in tissue called brown fat. The cells of brown fat are unlike other fat cells in these animals' bodies. Most other cells store chemical energy released during the breakdown of carbohydrates and fatty acids in the bonds of adenosine triphosphate (ATP). ATP acts as the central source of energy and growth of all organisms. Heat is mostly a waste product in ATP-producing cells. The heat generated by the brown fat tissue, however, helps the animal keep relatively comfortable even at subzero temperatures.

Sample Problem 17.4

Using the Heat of Reaction to Calculate Enthalpy Change

Calculate the amount of heat (in kJ) required to decompose 2.24 mol $NaHCO_3(s)$.

$$2NaHCO_3(s) + 85\ kJ \longrightarrow Na_2CO_3(s) + H_2O(l) + CO_2(g)$$

1 Analyze **List the knowns and the unknown.** Use the thermochemical equation above to write a conversion factor relating kilojoules of heat and moles of $NaHCO_3$. Then use the conversion factor to determine ΔH for 2.24 mol $NaHCO_3$.

KNOWNS

amount of $NaHCO_3(s)$ that decomposes = 2.24 mol

ΔH = 85 kJ for 2 mol $NaHCO_3$

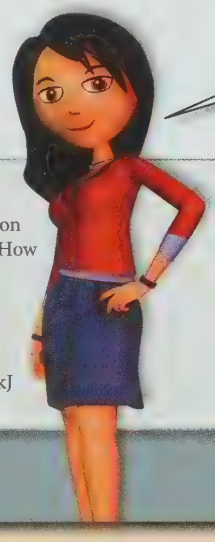
UNKNOWN

ΔH = ? kJ for 2.24 mol $NaHCO_3$

2 Calculate **Solve for the unknown.**

Write the conversion factor relating kJ of heat and moles of $NaHCO_3$.

$$\frac{85\ kJ}{2\ mol\ NaHCO_3(s)}$$



The thermochemical equation indicates that 85 kJ are needed to decompose 2 mol $NaHCO_3(s)$.

Using dimensional analysis, solve for ΔH.

$$\Delta H = 2.24\ \cancel{mol\ NaHCO_3(s)} \times \frac{85\ kJ}{2\ \cancel{mol\ NaHCO_3(s)}}$$

$$= 95\ kJ$$

3 Evaluate **Does the result make sense?** The 85 kJ in the thermochemical equation refers to the decomposition of 2 mol $NaHCO_3(s)$. Therefore, the decomposition of 2.24 mol should absorb more heat than 85 kJ. The answer of 95 kJ is consistent with this estimate.

To do Problem 15, first convert from mass of CS_2 to moles of CS_2.

14. The production of iron and carbon dioxide from iron(III) oxide and carbon monoxide is an exothermic reaction. How many kilojoules of heat are produced when 3.40 mol Fe_2O_3 reacts with an excess of CO?

$$Fe_2O_3(s) + 3CO(g) \longrightarrow 2Fe(s) + 3CO_2(g) + 26.3\ kJ$$

15. When carbon disulfide is formed from its elements, heat is absorbed. Calculate the amount of heat (in kJ) absorbed when 5.66 g of carbon disulfide is formed.

$$C(s) + 2S(s) \longrightarrow CS_2(l)$$

$$\Delta H = 89.3\ kJ$$

Foundations for Math

CONVERSION FACTORS Stress to students that it is essential that they include units throughout a problem, not only for the given quantities but also for the conversion factors. Point out that this is true for two reasons: 1) cancelling the units helps demonstrate that the conversion factors are oriented correctly; and 2) the final answer will contain the correct units.

In **Sample Problem 17.4,** a conversion factor relating kilojoules of heat and moles of sodium bicarbonate is needed. By including the units, you can see that the conversion factor should be written with mol $NaHCO_3$ in the denominator so that they will cancel. This means that kJ should be in the numerator, and the final answer will have the desired units for heat.

Explain

Sample Practice Problem

Calculate the amount of heat (in kJ) required to decompose 2.0 mol hydrogen peroxide in the following decomposition reaction.

$$2H_2O_2(l) \rightarrow l) + O_2(g)$$

ΔH = –98.2 kJ (for 1 mol H_2O_2)

(–196.0 kJ)

Extend

CRITICAL THINKING Tell students that many metals react with oxygen to produce metal oxides. Have students research the combustion reactions of a series of selected metals (e.g., Mg, Ca, Fe). Students should write thermochemical equations for each reaction and compare the relative amounts of heat released in each case. Ask students to describe any trend(s) they observe.

Answers

14. 89.4 kJ
15. 6.63 kJ

Extend

Thermochemical Equations

Connect to TECHNOLOGY

Have students research and write a report on a topic related to solar power that draws on their newly gained knowledge of enthalpy changes. Possible topics include:

- hybrid solar power plants that combine solar energy collection with fossil fuel combustion
- mirror technologies used in solar power plants
- heat-transfer fluids used in CSP technologies (e.g., air, steam, molten salt, oil)
- houses and other buildings that have solar-powered heating and hot-water systems
- photovoltaic technologies used in solar power plants, solar cars, and solar houses

Evaluate

Informal Assessment

To determine students' knowledge about measuring and expressing heat changes, pose the following questions:

A. Explain the difference between H and ΔH. *(H is enthalpy or heat content; ΔH represents a change in heat content.)*

B. Use the data in Table 17.2 to write the thermochemical equation for the combustion of propane.

($C_3H_8(g) + 5O_2(g) \rightarrow 3CO_2(g) + 4H_2O(l)$; $\Delta H = -2220$ kJ)

Then have students complete the 17.2 Lesson Check.

Reteach

Select a substance from Table 17.2, and write the thermochemical equation on the chalkboard. Discuss the ΔH for the reaction, why it is negative or positive, and draw the enthalpy diagram for the reaction. Remind students that heat is the energy that flows into or out of a thermodynamic system because of differences in temperature between the system and its surroundings. Remind students that the total energy, potential and kinetic, of the system and the surroundings must remain the same in any chemical or physical process.

Figure 17.10 Combustion
The combustion of natural gas is an exothermic reaction. As bonds in methane (the main component of natural gas) and oxygen are broken and bonds in carbon dioxide and water are formed, large amounts of energy are released.

Table 17.2

Heats of Combustion at 25°C

Substance	Formula	ΔH (kJ/mol)
Hydrogen	$H_2(g)$	−286
Carbon	C(s, graphite)	−394
Methane	$CH_4(g)$	−890
Acetylene	$C_2H_2(g)$	−1300
Ethanol	$C_2H_6O(l)$	−1368
Propane	$C_3H_8(g)$	−2220
Glucose	$C_6H_{12}O_6(s)$	−2808
Octane	$C_8H_{18}(l)$	−5471
Sucrose	$C_{12}H_{22}O_{11}(s)$	−5645

Heats of Combustion Table 17.2 lists heats of combustion for some common substances. The **heat of combustion** is the heat of reaction for the complete burning of one mole of a substance. Figure 17.10 shows the combustion of natural gas, which is mostly methane. Small amounts of natural gas within crude oil are burned off at oil refineries. This is an exothermic reaction.

$$CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(l) + 890 \text{ kJ}$$

You can also write this equation as follows:

$$CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(l) \qquad \Delta H = -890 \text{ kJ}$$

Burning 1 mol of methane releases 890 kJ of heat. The heat of combustion (ΔH) for this reaction is −890 kJ per mole of methane burned.

Like other heats of reaction, heats of combustion are reported as the enthalpy changes when the reactions are carried out at 101.3 kPa of pressure and the reactants and products are in their physical states at 25°C.

17.2 LessonCheck

16. Describe How can you determine the value of ΔH of a reaction?

17. Review How are enthalpy changes expressed in chemical equations?

18. Calculate A lead mass is heated and placed in a foam cup calorimeter containing 40.0 mL of water at 17.0°C. The water reaches a temperature of 20.0°C. How many joules of heat were released by the lead?

19. Explain What does the term *heat of combustion* refer to?

20. Describe When 2 mol of solid magnesium (Mg) combines with 1 mol of oxygen gas (O_2), 2 mol of solid magnesium oxide (MgO) is formed and 1204 kJ of heat is released. Write the thermochemical equation for this combustion reaction.

21. Calculate Gasohol contains ethanol, $C_2H_6O(l)$. When ethanol burns, it reacts with $O_2(g)$ to produce $CO_2(g)$ and $H_2O(l)$. How much heat is released when 12.5 g of ethanol burns?

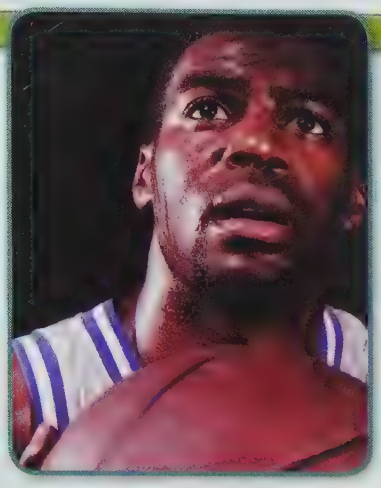
$$C_2H_6O(l) + 3O_2(g) \longrightarrow 2CO_2(g) + 3H_2O(l)$$
$$\Delta H = -1368 \text{ kJ}$$

Lesson Check Answers

16. The value of ΔH of a reaction can be determined by measuring the heat flow of the reaction at constant pressure.

17. The enthalpy change in a chemical reaction can be written as either a reactant or a product.

18. 520 J



19. Heat of combustion is the heat of reaction for the complete burning of one mole of a substance.

20. $2Mg(s) + O_2(g) \rightarrow 2MgO(s) +$ 1204 kJ, or $2Mg(s) + O_2(g) \rightarrow 2MgO(s)$ $\Delta H = -1204$ kJ

21. 3.72×10^2 kJ

17.3 Heat in Changes of State

C.6.3 Heat flow and temperature change problems, C.6.4 Exothermic and endothermic reactions

CHEMISTRY & YOU

Q: *Why does sweating help cool you off?* An athlete can burn a lot of calories during a game. These calories are either used to do work or are released as heat. When your body heats up, you start to sweat. The evaporation of sweat is your body's way of cooling itself to a normal temperature.

Key Questions

- ***What is the relationship between molar heat of fusion and molar heat of solidification?***
- ***What is the relationship between molar heat of vaporization and molar heat of condensation?***
- ***What thermochemical changes can occur when a solution forms?***

Vocabulary

- molar heat of fusion
- molar heat of solidification
- molar heat of vaporization
- molar heat of condensation
- molar heat of solution

Heats of Fusion and Solidification

What is the relationship between molar heat of fusion and molar heat of solidification?

What happens if you place an ice cube on a table in a warm room? The ice cube is the system, and the table and air around it are the surroundings. The ice absorbs heat from its surroundings and begins to melt. The temperature of the ice and the liquid water produced remains at 0°C until all of the ice has melted.

Like ice cubes, all solids absorb heat as they melt to become liquids. The gain of heat causes a change of state instead of a change in temperature. Whenever a change of state occurs by a gain or loss of heat, the temperature of the substance undergoing the change remains constant. The heat absorbed by one mole of a solid substance as it melts to a liquid at a constant temperature is the **molar heat of fusion** (ΔH_{fus}). The **molar heat of solidification** (ΔH_{solid}) is the heat lost when one mole of a liquid substance solidifies at a constant temperature. **The quantity of heat absorbed by a melting solid is exactly the same as the quantity of heat released when the liquid solidifies; that is, $\Delta H_{fus} = -\Delta H_{solid}$.**

The melting of 1 mol of ice at 0°C to 1 mol of liquid water at 0°C requires the absorption of 6.01 kJ of heat. This quantity of heat is the molar heat of fusion of water. Likewise, the conversion of 1 mol of liquid water at 0°C to 1 mol of ice at 0°C releases 6.01 kJ of heat. This quantity of heat is the molar heat of solidification of water.

$$H_2O(s) \longrightarrow H_2O(l) \qquad \Delta H_{fus} = 6.01 \text{ kJ/mol}$$

$$H_2O(l) \longrightarrow H_2O(s) \qquad \Delta H_{solid} = -6.01 \text{ kJ/mol}$$

Focus on ELL

1 CONTENT AND LANGUAGE Divide the class into 5 groups and assign each group one vocabulary term. Encourage each group to create a picture or word equation to illustrate the meaning of their word. Have groups present their illustrations to the class, allowing time for students to ask questions for clarification. Provide students with the accepted definitions for each term and allow them to make corrections to their illustrations where necessary.

2 FRONTLOAD THE LESSON Review phase changes and phase diagrams with students, and verify that students have a clear understanding of the difference between endothermic and exothermic processes. Demonstrate the use of chemical equations to represent phase changes.

3 COMPREHENSIBLE INPUT Prior to beginning the Quick Lab, review Figure 17.11. Ask students to identify which arrow represents ice melting. Point out that this figure can be used as a reference to identify whether a process is endothermic or exothermic and to determine which mathematical sign should be associated with a given enthalpy change.

Key Objectives

17.3.1 COMPARE the quantity of heat absorbed by a melting solid to the quantity of heat released when the liquid solidifies.

17.3.2 COMPARE the quantity of heat absorbed by a vaporizing liquid to the quantity of heat released when the vapor condenses.

17.3.3 DESCRIBE thermochemical changes that occur when a solution forms.

Reading and Study Workbook, Lesson 17.3

Available Online or on Digital Media:

- Teaching Resources, Lesson 17.3 Review
- Small-Scale Laboratory Manual, Lab 27

PearsonChem.com

Engage

CHEMISTRY & YOU Have students read the opening text and study the photograph. Remind them that heat is generated during chemical reactions in muscles, but the movement of heat from the point of reaction to the surface of the skin is a series of transfers between body tissues and fluids. Some heat is dissipated through radiation, convection and conduction. The rest is dissipated during the evaporation of sweat. **Ask** What type of process is evaporation? *(a change in phase from a liquid to a gas)*

IN ACADEMIC STANDARDS for SCIENCE

- Develop explanations based on reproducible data and observations gathered during laboratory investigations.
- Clearly communicate their ideas and results of investigations verbally and in written form using tables, graphs, diagrams, and photographs.
- Apply standard techniques in laboratory investigations to measure physical quantities in appropriate units and convert known quantities to other units as necessary.

Also covered C.6.3, C.6.4.

Activate Prior Knowledge

Remind students that evaporation is a physical change from a liquid state to a gas (vapor).
Ask On a molecular level, what is the difference between liquid water and water vapor? *(In the vapor phase, the water molecules are farther apart and not as strongly attracted to each other.)* **Ask** What must happen for a liquid to change into a gas? *(Energy must be added to overcome the attraction.)* **Ask** Is evaporation endothermic or exothermic? *(endothermic)*

Foundations for Reading

BUILD VOCABULARY Point out that each vocabulary word has the same first three words, "molar heat of...". Have students predict the meaning of each vocabulary term and then confirm or modify their predictions once they read the appropriate section.

READING STRATEGY After students read about the enthalpy change that occurs during a particular phase change, have them examine Figure 17.11 and find the arrow that applies to that phase change. Tell students to look for other useful visual aids in the lesson that will help them understand their reading, or to create their own as needed.

Explore

Heats of Fusion and Solidification

Class Activity

PURPOSE Students will measure temperatures during melting of ice and boiling of water.

MATERIALS beaker, water, boiling chips, hot plate, thermometer, ice cubes, foam cup

PROCEDURE Have students record the temperature of gently boiling water in a beaker (use boiling chips) and of melting ice in a foam cup. Students should record the temperatures every 30 seconds.

EXPECTED OUTCOMES Even if the thermometers do not record exactly 100°C or 0°C, students should note that the temperature does not change during boiling and melting.

Sample Practice Problem

How much heat must be removed to freeze a container of water if the water has a mass of 150 g? *(50.0 kJ)*

Sample Problem 17.5

Using the Heat of Fusion in Phase-Change Calculations

How many grams of ice at 0°C will melt if 2.25 kJ of heat are added?

1 Analyze **List the knowns and the unknown.** Find the number of moles of ice that can be melted by the addition of 2.25 kJ of heat. Convert moles of ice to grams of ice.

KNOWNS
Initial and final temperatures are 0°C
$\Delta H_{fus} = 6.01$ kJ/mol
$\Delta H = 2.25$ kJ

UNKNOWN
$m_{ice} = ?$ g

2 Calculate **Solve for the unknown.**

Start by expressing ΔH_{fus} as a conversion factor. $\frac{1 \text{ mol } H_2O(s)}{6.01 \text{ kJ}}$ Use the thermochemical equation $H_2O(s) + 6.01 \text{ kJ} \longrightarrow H_2O(l)$

Express the molar mass of ice as a conversion factor. $\frac{18.0 \text{ g } H_2O(s)}{1 \text{ mol } H_2O(s)}$

Multiply the known enthalpy change by the conversion factors.

$$m_{ice} = 2.25 \text{ kJ} \times \frac{1 \text{ mol } H_2O(s)}{6.01 \text{ kJ}} \times \frac{18.0 \text{ g } H_2O(s)}{1 \text{ mol } H_2O(s)}$$

$$= 6.74 \text{ g } H_2O(s)$$

3 Evaluate **Does the result make sense?** To melt 1 mol of ice, 6.01 kJ of energy is required. Only about one third of this amount of heat (roughly 2 kJ) is available, so only about one-third mol of ice, or 18.0 g/3 = 6 g, should melt. This estimate is close to the calculated answer.

22. How many grams of ice at 0°C could be melted by the addition of 0.400 kJ of heat?

23. How many kilojoules of heat are required to melt a 50.0-g popsicle at 0°C? Assume the popsicle has the same molar mass and heat of fusion as water.

To do Problem 23, first convert from mass to moles. Then, express ΔH_{fus} as a conversion factor to convert from moles of ice to kJ of heat.

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in pairs to complete the lab. Make sure each ELL student is paired with a stronger English proficient student. Allow time for students to silently read and translate the lab into their own language if necessary.

BEGINNING: LOW Use the think-aloud strategy while modeling the procedure.

HIGH Rewrite the procedure using smaller steps and fewer words.

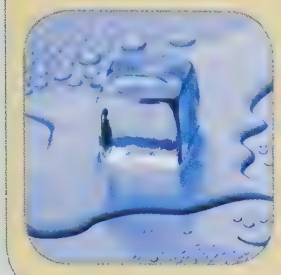
INTERMEDIATE: LOW Provide students with a chart to record their observations and measurements.

HIGH Demonstrate how to use the change in mass of H_2O and its density to calculate the mass of the ice.

ADVANCED: LOW/HIGH Have students assist lower proficiency students with their calculations.

Quick Lab

Purpose To estimate the heat of fusion of ice



Heat of Fusion of Ice

Materials

- 100-ml graduated cylinder
- hot tap water
- foam cup
- thermometer
- ice

Procedure

1. Fill the graduated cylinder with hot tap water and let stand for 1 minute. Pour the water into the sink.
2. Measure 70 mL of hot water. Pour the water into the foam cup. Measure the temperature of the water.
3. Add an ice cube to the cup of water. Gently swirl the cup. Measure the temperature of the water as soon as the ice cube has completely melted.
4. Pour the water into the graduated cylinder and measure the volume.

Analyze and Conclude

1. **Calculate** Determine the mass of the ice. (*Hint:* Use the increase in the volume of water and the density of water.) Convert this mass into moles.
2. **Calculate** Determine the heat transferred from the water to the ice using the mass of the hot water, the specific heat of liquid water, and the change in temperature.
3. **Calculate** Determine ΔH_{fus} of ice (kJ/mol) by dividing the heat transferred from the water by the moles of ice melted.
4. **Perform Error Analysis** Compare your experimental value of ΔH_{fus} of ice with the accepted value of 6.01 kJ/mol. Account for any error.

Heats of Vaporization and Condensation

What is the relationship between molar heat of vaporization and molar heat of condensation?

A liquid that absorbs heat at its boiling point becomes a vapor. The amount of heat required to vaporize one mole of a given liquid at a constant temperature is called its **molar heat of vaporization** (ΔH_{vap}). Table 17.3 lists the molar heats of vaporization for several substances at their normal boiling points.

The molar heat of vaporization of water is 40.7 kJ/mol. This means that it takes 40.7 kJ of energy to convert 1 mol of liquid water to 1 mol of water vapor at the normal boiling point of water (100°C at 101.3 kPa).

$$H_2O(l) \longrightarrow H_2O(g) \qquad \Delta H_{vap} = 40.7 \text{ kJ/mol}$$

Diethyl ether ($C_4H_{10}O$) has a boiling point of 34.6°C and a molar heat of vaporization (ΔH_{vap}) of 26.5 kJ/mol. If liquid diethyl ether is poured into a beaker on a warm, humid day, the ether will absorb heat from the beaker walls and evaporate rapidly. If the beaker loses enough heat, the water vapor in the air may condense and freeze on the beaker walls, forming a coating of frost on the outside of the beaker.

$$C_4H_{10}O(l) \longrightarrow C_4H_{10}O(g) \qquad \Delta H_{vap} = 26.5 \text{ kJ/mol}$$

Table 17.3

Heats of Physical Change

Substance	ΔH_{fus} (kJ/mol)	ΔH_{vap} (kJ/mol)
Ammonia (NH_3)	5.66	23.3
Ethanol (C_2H_6O)	4.93	38.6
Hydrogen (H_2)	0.12	0.90
Methanol (CH_4O)	3.22	35.2
Oxygen (O_2)	0.44	6.82
Water (H_2O)	6.01	40.7

LESSON 17.3

Quick Lab

OBJECTIVE Students will melt an ice cube and calculate the heat of fusion of ice.

SKILLS FOCUS observing, measuring, calculating, designing experiments

PREP TIME 10 minutes

CLASS TIME 20 minutes

MATERIALS 100-mL graduated cylinder, hot water, foam cup, thermometer, temperature probe (optional), ice

ADVANCE PREPARATION Provide students with a source of water between 50°C and 60°C.

SAFETY Students should wear safety goggles. Warn students not to use the thermometer as a stirring rod and discuss what students should do if the thermometer breaks.

TEACHING TIPS Remind students to make all temperature measurements to the nearest tenth of a degree and all volume measurements to the nearest milliliter. Small ice cubes or crushed ice work best.

EXPECTED OUTCOME Students should calculate values of approximately 6.01 kJ/mol for the heat of fusion of ice.

ANALYZE AND CONCLUDE

1. The mass of ice will be equal to the final volume of water minus the initial volume of water, expressed in grams.
2. Answers will depend on what the students measure for the change in temperature. Students will need to multiply the volume of water by the density of water to get the mass of water. Then they can solve for the heat transferred from the water to the ice.
3. See Expected Outcome.
4. See Expected Outcome. If the experiment is not done quickly, loss of heat to the classroom may cause ΔT to be too large, resulting in a larger ΔH_{fus}. Careful reading of the thermometer and graduated cylinder is crucial. Some water may adhere to the thermometer and cup; this may affect volume measurements.

FOR ENRICHMENT Have students suggest how to revise the procedures to achieve more accurate results. Then, have them design a new experiment that incorporates their suggestions for revising the procedure. If students perform the new experiment, they should compare the results of the two experiments and calculate the respective percent errors.

Answers

22. 1.20 g
23. 16.7 kJ

Explain

Heats of Vaporization and Condensation

CHEMISTRY & YOU When the sweat evaporates, it absorbs heat from your body leaving you feeling cooler.

CRITICAL THINKING Direct students' attention to Figure 17.12. **Ask** How would the rate of heating affect the heating curve? *(The faster the rate of heating is, the steeper the slope of the curve will be.)*

Explore

Teacher Demo

PURPOSE Students will observe the release of heat when a liquid solidifies.

MATERIALS 3 wide-mouth test tubes, sodium thiosulfate pentahydrate, hot water bath, 30°C water bath, thermometers, stirring rods

PROCEDURE Set three wide-mouth test tubes each containing about 20 grams of sodium thiosulfate pentahydrate ($Na_2S_2O_3 \cdot 5H_2O$) in a hot water bath until the chemical is completely melted. Transfer the tubes to a cool water bath at about 30°C. Let the test tubes sit undisturbed until they are close to 30°C and feel lukewarm to touch. Give the tubes to three student volunteers at different locations in the classroom so that many students can see and feel what happens. Give each volunteer a thermometer and a seed crystal. Ask them to quickly take the temperature of the liquid, drop in the seed crystal, and stir gently.

EXPECTED OUTCOMES The temperature of the test tube will rise. Students will observe the change by touching the test tube and reading the thermometer.

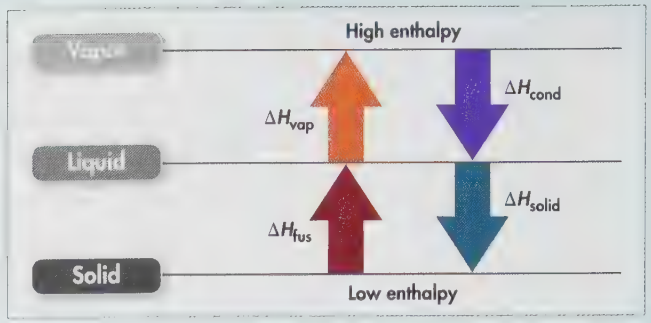


Figure 17.11 Changes in State Enthalpy changes accompany changes in state. Fusion and vaporization are endothermic processes. Solidification and condensation are exothermic processes.
Interpret Diagrams *Which arrows represent processes that release heat to the surroundings?*

Condensation is the exact opposite of vaporization. When a vapor condenses, heat is released. The **molar heat of condensation** (ΔH_{cond}) is the amount of heat released when one mole of a vapor condenses at its normal boiling point. **The quantity of heat absorbed by a vaporizing liquid is exactly the same as the quantity of heat released when the vapor condenses; that is, $\Delta H_{vap} = -\Delta H_{cond}$.** Figure 17.11 shows the relationships between the molar heat of fusion and molar heat of solidification and between the molar heat of vaporization and molar heat of condensation.

Figure 17.12 summarizes the enthalpy changes that occur as ice is heated to a liquid and then to a vapor. You should be able to identify certain trends regarding the temperature during changes of state and the energy requirements that accompany these changes from the graph. The large values for ΔH_{vap} and ΔH_{cond} are the reason hot vapors such as steam can be very dangerous. You can receive a scalding burn from steam when the heat of condensation is released as the steam touches your skin.

$$H_2O(g) \longrightarrow H_2O(l) \qquad \Delta H_{cond} = -40.7 \text{ kJ/mol}$$

CHEMISTRY & YOU

Q: *Explain why the evaporation of sweat off your body helps to cool you off.*

Interpret Graphs

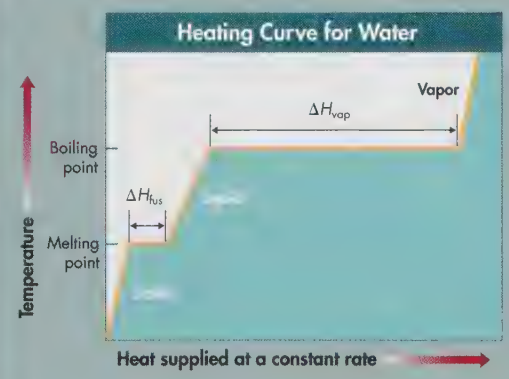

Figure 17.12 A heating curve graphically describes the enthalpy changes that take place during phase changes.
a. Identify In which region(s) of the graph is temperature constant?
b. Compare How does the amount of energy required to melt a given mass of ice compare to the energy required to vaporize the same mass of liquid water? Explain.
c. Apply Concepts Which region of the graph represents the coexistence of solid and liquid? Liquid and vapor?

Remember: The temperature of a substance remains constant during a change in state.

UbD **Check for Understanding**

BIG IDEA How can you determine the amount of energy absorbed or released in a chemical or physical process?

Give students 60 seconds to explain, orally, pictorially, or in writing, how to use molar heats to determine the quantity of heat absorbed by a melting solid and the quantity of heat released when a liquid solidifies. *(The molar heat of fusion should be used to determine the energy absorbed by a melting solid and the molar heat of solidification should be used to determine the energy released by a solidifying liquid.)*

ADJUST INSTRUCTION If students struggle to answer, have them reread the Heats of Fusion and Solidification section, then review the two equations at the end of the section and Sample Problem 17.5. Clarify that, except for mathematical sign, a substance's molar heat of fusion is exactly the same as its molar heat of solidification.

Sample Problem 17.6

Using the Heat of Vaporization in Phase-Change Calculations

How much heat (in kJ) is absorbed when 24.8 g $H_2O(l)$ at 100°C and 101.3 kPa is converted to $H_2O(g)$ at 100°C?

1 Analyze **List the knowns and the unknown.** First, convert grams of water to moles of water. Then, find the amount of heat that is absorbed when the liquid water is converted to steam.

KNOWNS

Initial and final conditions are 100°C and 101.3 kPa
mass of liquid water converted to steam = 24.8 g
ΔH_{vap} = 40.7 kJ/mol

UNKNOWN

ΔH = ? kJ

2 Calculate **Solve for the unknown.**

Start by expressing the molar mass of water as a conversion factor.

$$\frac{1 \text{ mol } H_2O(l)}{18.0 \text{ g } H_2O(l)}$$

Express ΔH_{vap} as a conversion factor.

$$\frac{40.7 \text{ kJ}}{1 \text{ mol } H_2O(l)}$$

Use the thermochemical equation $H_2O(l) + 40.7 \text{ kJ} \longrightarrow H_2O(g)$

Multiply the mass of water in grams by the conversion factors.

$$\Delta H = 24.8 \text{ g } \cancel{H_2O(l)} \times \frac{1 \cancel{\text{ mol } H_2O(l)}}{18.0 \cancel{\text{ g } H_2O(l)}} \times \frac{40.7 \text{ kJ}}{1 \cancel{\text{ mol } H_2O(l)}}$$

$$= 56.1 \text{ kJ}$$

3 Evaluate **Does the result make sense?** Knowing the molar mass of water is 18.0 g/mol, 24.8 g $H_2O(l)$ can be estimated to be somewhat less than 1.5 mol H_2O. The calculated enthalpy change should be a little less than 1.5 ~~mol~~ × 40 kJ/~~mol~~ = 60 kJ, and it is.

24. How much heat is absorbed when 63.7 g $H_2O(l)$ at 100°C and 101.3 kPa is converted to $H_2O(g)$ at 100°C? Express your answer in kJ.

25. How many kilojoules of heat are absorbed when 0.46 g of chloroethane (C_2H_5Cl, bp 12.3°C) vaporizes at its normal boiling point? The molar heat of vaporization of chloroethane is 24.7 kJ/mol.

For Problem 25, start by writing the thermochemical equation for the vaporization of chloroethane.

Differentiated Instruction

LPR LESS PROFICIENT READERS Provide at least two brands of cold or hot packs. Have students activate the packs at exactly the same time and then measure the maximum or minimum temperature achieved. Have students determine how long the packs remain effective. Ask students to decide, based on the data and the cost of each pack, which brand provided the best value.

ELL ENGLISH LANGUAGE LEARNERS Have students create a flow chart to summarize the enthalpy changes involved when a substance undergoes a phase change. Guide students to study fusion and solidification and vaporization and condensation in pairs. Allow students to create their charts using symbols, colors, and their own words so the diagrams are useful to them for studying.

L3 ADVANCED STUDENTS Have students devise an experiment to test whether initial water temperature affects the rate at which water freezes.

Explain

SUMMARIZE Have students look up the molar heat of fusion, the molar heat of vaporization, and the specific heat of ethanol (grain alcohol) in Tables 17.1 and 17.3. Tell students that ethanol freezes at 158.7 K and boils at 351.5 K. Have students summarize the enthalpy changes that occurs as solid ethanol is heated to a liquid and then to a gas by constructing a heating curve like the one shown in Figure 17.12 for water. Ask students to find the amount of heat necessary to convert 1 mole of solid ethanol to ethanol vapor.

Sample Practice Problem

The molar heat of vaporization of water is 40.7 kJ/mol. How many kilojoules of heat are required to vaporize 60.5 g of water at its boiling point of 100°C? *(136 kJ)*

Answers

INTERPRET GRAPHS

a. at the melting point and the boiling point

b. It takes much less energy to melt a given mass of ice than to vaporize the same mass of water. The ΔH_{fus} is much smaller than ΔH_{vap}.

Heat of Solution

USE VISUALS Direct students' attention to Figure 17.13. **Ask** Is the process that occurs in a cold pack endothermic or exothermic? How do you know? *(Endothermic; heat is absorbed and the temperature of the surroundings decreases.)* **Ask** In which direction is heat flowing? *(from the surroundings to the system)* **Ask** Is the process in a hot pack endothermic or exothermic? How do you know? *(Exothermic; heat is released and the temperature of the surroundings increases.)* **Ask** In which direction is heat flowing? *(from the system to the surroundings)*

Explore

Class Activity

Purchase a number of hot and cold packs used by athletes and show the class how they work. Most instant cold and hot packs operate by utilizing the heat released or abosorbed when certain substances dissolve in water. Hot packs usually contain calcium chloride, $CaCl_2(s)$, while cold packs usually contain ammonium nitrate, $NH_4NO_3(s)$. If the labels specify the amount of salt contained in each package, have students use the molar heats of solution provided in the text to calculate the amount of heat absorbed and released in each case.

Heat of Solution

What thermochemical changes can occur when a solution forms?

If you've ever used a hot pack or a cold pack, then you have felt the enthalpy changes that occur when a solute dissolves in a solvent. **During the formation of a solution, heat is either released or absorbed.** The enthalpy change caused by the dissolution of one mole of substance is the **molar heat of solution** (ΔH_{soln}). For example, when 1 mol of sodium hydroxide, NaOH(s), is dissolved in water, the solution can become so hot that it steams. The heat from this process is released as the sodium ions and the hydroxide ions interact with the water. The temperature of the solution increases, releasing 44.5 kJ of heat as the molar heat of solution.

$$NaOH(s) \longrightarrow Na^+(aq) + OH^-(aq)$$
$$\Delta H_{soln} = -44.5 \text{ kJ/mol}$$

A practical application of an exothermic dissolution process is a hot pack. In a hot pack, calcium chloride, $CaCl_2(s)$, mixes with water, producing heat.

$$CaCl_2(s) \longrightarrow Ca^{2+}(aq) + 2Cl^-(aq)$$
$$\Delta H_{soln} = -82.8 \text{ kJ/mol}$$

The dissolution of ammonium nitrate, $NH_4NO_3(s)$, is an example of an endothermic process. When ammonium nitrate dissolves in water, the solution becomes so cold that frost may form on the outside of the container. The cold pack in Figure 17.13 contains solid ammonium nitrate crystals and water. Once the solute dissolves in the solvent, the pack becomes cold. In this case, the solution process absorbs energy from the surroundings.

$$NH_4NO_3(s) \longrightarrow NH_4^+(aq) + NO_3^-(aq)$$
$$\Delta H_{soln} = 25.7 \text{ kJ/mol}$$

Figure 17.13 Cold Pack
The cold pack shown has two sealed plastic bags, one inside the other. The outer bag contains ammonium nitrate crystals. The inner bag contains liquid water. When the pack is squeezed, the inner bag breaks, allowing the ammonium nitrate and water to mix.
Infer ***How would you define the system and the surroundings in this process?***

Foundations for Math

MULTIPLYING SIGNIFICANT FIGURES Remind students that when multiplying measured quantities, the final result should have the same number of significant figures as the measurement with the least number of significant figures. For a thorough review of significant figures, have students revisit section 3.1 of the text.

In **Sample Problem 17.7,** multiplying 2.50 by –44.5 yields –111.25. Some students may think that they should report the answer as –111.2, because both multipliers have digits to the right of the decimal. Stress that the presence of a decimal point in a multiplier is relevant only in the respect that its presence makes a 0 significant, as it does in 2.50. The presence of a decimal in both multipliers is not a prerequisite for the presence of a decimal in the reported answer. However, if the answer were to be reported in scientific notation, then a decimal *would* be necessary in order to insure that the answer contained three significant figures.

574 Chapter 17 • Lesson 3

Sample Problem 17.7

Calculating the Enthalpy Change in Solution Formation

How much heat (in kJ) is released when 2.50 mol NaOH(*s*) is dissolved in water?

1 Analyze **List the knowns and the unknown.** Use the heat of solution for the dissolution of NaOH(*s*) in water to solve for the amount of heat released (ΔH).

KNOWNS

$\Delta H_{soln} = -44.5$ kJ/mol

amount of NaOH(*s*) dissolved = 2.50 mol

UNKNOWN

$\Delta H = ?$ kJ

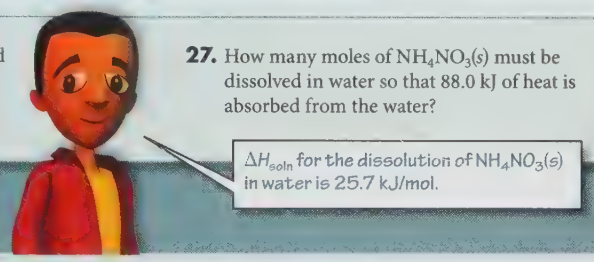
2 Calculate **Solve for the unknown.**

Start by expressing ΔH_{soln} as a conversion factor.

$$\frac{-44.5 \text{ kJ}}{1 \text{ mol NaOH}(s)}$$

Use the thermochemical equation

$$NaOH(s) \longrightarrow Na^+(aq) + OH^-(aq) + 44.5 \text{ kJ/mol}$$



Multiply the number of moles by the conversion factor.

$$\Delta H = 2.50 \text{ mol NaOH}(s) \times \frac{-44.5 \text{ kJ}}{1 \text{ mol NaOH}(s)} = -111 \text{ kJ}$$

3 Evaluate **Does the result make sense?** ΔH is 2.5 times greater than ΔH_{soln}, as it should be. Also, ΔH should be negative, as the dissolution of NaOH(*s*) in water is exothermic.

26. How much heat (in kJ) is released when 0.677 mol NaOH(*s*) is dissolved in water?

27. How many moles of $NH_4NO_3(s)$ must be dissolved in water so that 88.0 kJ of heat is absorbed from the water?

17.3 LessonCheck

28. **Describe** How does the molar heat of fusion of a substance compare to its molar heat of solidification?

29. **Describe** How does the molar heat of vaporization of a substance compare to its molar heat of condensation?

30. **Identify** What enthalpy changes occur when a solute dissolves in a solvent?

31. **Calculate** How much heat must be removed to freeze a tray of ice cubes at 0°C if the water has a mass of 225 g?

32. **Calculate** How many kilojoules of heat are required to vaporize 50.0 g of ethanol, C_2H_6O? The boiling point of ethanol is 78.3°C. Its molar heat of vaporization is 38.6 kJ/mol.

33. **Calculate** How many kilojoules of heat are released when 25.0 g of NaOH(*s*) is dissolved in water?

BIG IDEA MATTER AND ENERGY

34. Use what you know about hydrogen bonding to explain why water has such a large heat of vaporization.

Lesson Check Answers

28. Molar heat of fusion and molar heat of solidification have an identical numerical value but are of opposite sign.

29. Molar heat of vaporization and molar heat of condensation have an identical numerical value but are of opposite sign.

30. Heat is either released or absorbed in the formation of a solution.

31. 75.1 KJ

32. 42.0 KJ

33. –27.9 KJ

34. Water molecules are very polar, and many hydrogen bonds form among the molecules. It takes a great deal of energy to break the hydrogen bonds and pull the water molecules apart.

Sample Practice Problem

How many kilojoules of heat are released when 46.0 g of $CaCl_2$ are dissolved in water? *(–34.3 kJ)*

Evaluate

Informal Assessment

Ask students to sketch a heating curve for 1 mol of ice being heated from –10°C to 110°C. Have students write brief explanations of their graphs. Ask students to calculate how much energy would be required to change 54.0 g of ice at –10.0°C to water vapor at 110°C. *(165 kJ)* Then have students complete the 17.3 Lesson Check.

Reteach

Display Figure 17.12 on an overhead projector. Remind students that during endothermic phase changes, melting or evaporation, energy absorbed does not increase the temperature because the energy is being used to overcome attractions between particles. The energy can be released back to the surroundings during the opposing exothermic phase change, condensation or freezing.

Answers

FIGURE 17.13 The system is the cold pack; the athlete and the air around the cold pack constitute the surroundings.

27. 3.42 mol $NH_4NO_3(s)$

CHEMISTRY & YOU Engage students in a discussion of the photo of the geothermal energy plant and the swimming pool. Explain that the people are swimming in the Blue Lagoon, Iceland. The saltwater output from the nearby geothermal energy plant produces a pool with a water temperature of about 40°C.

Pose the following question to students:

If geothermal energy is a virtually unlimited supply of heat and power, what might be some reasons that it is not more widely used?

You may need to guide students by asking the following questions:

- What would be the heat source for the power plant?
- How would this heat source be accessed?
- Where are similar heat sources located in relation to population centers?

Explain

START A CONVERSATION One type of geothermal power plant, called a *dry steam design,* has two nearby wells. An *injection well* pumps water down onto hot underground rock where it changes to steam. A nearby *production well* pumps this dry steam up from hot underground rock and uses it to spin a turbine. The turbine then turns a generator for the production of electricity. Enlist students' help to draw a diagram on the board of this type of system. Discuss how energy is taken into the plant or released during the process.

Geothermal Energy

Deep within Earth lies a powerful source of clean, renewable energy—the heat of Earth's interior. This energy, known as geothermal energy, is contained in the molten rock (magma), hot water, and steam of Earth's subsurface. Underground pockets of hot steam or heated water can be harnessed to generate heat and electricity, which can then be used to heat, cool, and provide electrical power to buildings.

The three main ways to tap into Earth's geothermal energy supply is through direct heating systems, heat pumps, and power plants. Using direct geothermal energy involves piping hot water from hot springs on Earth's surface directly into a building's heat system. Geothermal heat pumps are systems that make use of the relatively constant temperatures near Earth's surface. In the winter, the temperature below Earth's surface is warmer than the temperature of the air. Heat pumps are used to move heat from the ground to the surface through a series of pipes containing fluid. In the summer, the temperature below Earth's surface is cooler than the temperature of the air. Therefore, heat pumps can also be used to cool buildings by drawing heat away from a building and transferring it to the ground outside. Geothermal power plants tap into hot water and steam buried deep beneath Earth's surface. Hot steam or water can then be piped or pumped under high pressures from geothermal reservoirs into generators in the power plants on the surface. These power plants provide electricity to homes and businesses.

Pros & Cons

Advantages of Using Geothermal Energy	Disadvantages of Using Geothermal Energy
✔ **Low operating costs** Once the initial cost of constructing a geothermal energy facility has been paid for, there are no additional fuel costs.	✘ **Large initial expense** The initial cost of drilling wells to reach geothermal reservoirs and installing geothermal power plants is millions of dollars.
✔ **Clean Energy** Direct geothermal heating systems, geothermal heat pumps, and geothermal power plants emit little or no greenhouse gases.	✘ **Large space requirements** Geothermal heat pumps and power plants require large expanses of land for pipes and wells.
✔ **Sustainable Energy Source** Unlike fossil fuels, heat from beneath Earth's surface is a renewable resource.	✘ **Disruptive to the environment** Deep drilling can cause small earthquakes and hot water and steam can bring contaminants to Earth's surface.

21st Century Learning To be successful in the 21st century, students need skills and learning experiences that extend beyond subject matter mastery. The following project helps students build the following 21st Century Skills: *Critical Thinking and Problem Solving; Creativity and Innovation; Communication and Collaboration; Information, Media, and Technology Literacy; Productivity and Accountability; Global Awareness.*

POWER PLANT Divide students into groups of 3-5. Pose the following challenge. *A power company wants to develop a new geothermal plant in the United States. The type of plant and its location are undecided. Your consulting group is responsible for determining the best type of plant and the most appropriate location.* Prepare a written, illustrated report that identifies three possible locations for the plant that can serve areas with high population densities; identifies and explains the most appropriate plant type for the location, and summarizes the environmental impact on the ecosystem at each location.

THE POWER OF STEAM This power plant in Iceland taps into a geothermal reservoir 2000 meters below the surface. The steam, which can reach 240°C, is used to generate electricity. The condensed steam (liquid water) is then directed to a lagoon, where people bathe in it for healing and wellness purposes.

NATURAL HEAT Geysers and hot springs on Earth's surface indicate the presence of subsurface heat sources. These monkeys are keeping warm in one of Japan's hot springs.

Take It Further

1. Classify Describe the direction of heat flow when a geothermal heat pump is used to heat a building. What is the system and what are the surroundings? Is this process endothermic or exothermic?

2. Calculate How much energy is absorbed or released when: 535 kg of steam at 154°C cools to 100°C, the steam condenses at 100°C, and the liquid water cools from 100°C to 37°C?

3. Compare and Contrast Compare geothermal energy to one or more other sources of energy. Assess the costs and benefits of each.

Explain

CRITICAL THINKING Explain to students that a common use of geothermal energy is heat pumps. Unlike geothermal power plants, which use extreme underground temperatures, geothermal heat pumps operate at very shallow depths, sometimes as little as several meters below Earth's surface. The ground temperature here may be a cool 10°C. In winter, the heat pump transfers heat from the ground. In summer, it transfers heat into the ground. Write the following steps for a geothermal heat pump, and have students apply what they have learned about heat transfer in this chapter:

- A compressor increases the pressure of a gas, which increases its temperature.
- The hot gas moves to a condenser where it changes back to a liquid. **Ask** Does this step take in or release energy? Why? *(It releases energy. This is the molar heat of condensation.)*
- The cool liquid moves back to the evaporator and takes in geothermal energy. **Ask** What effect does the increase in energy have on the liquid? Why? *(It changes the liquid back into a gas. This is the molar heat of vaporization.)*

Extend

Connect to EARTH SCIENCE

Geothermal power plants are often considered to be a more environmentally-friendly source of electricity. However, there is some concern about how much of an environmental impact geothermal plants have. Divide students into small groups and assign them the task of researching the potential environmental effects of a modern geothermal plant versus a comparable fossil fuel plant. Afterwards, lead students in discussing the issue. Provide students with the opportunity to express their opinions.

Differentiated Instruction

L1 STRUGGLING STUDENTS Point out to students that in a geothermal power plant, steam is pumped from underground to power a turbine. It is then pumped back underground as water. Discuss with students whether this involves a state change or a chemical reaction *(state change)*, and whether it is an endothermic or exothermic reaction. *(Vaporization is endothermic. Condensation is exothermic.)*

LPR LESS PROFICIENT READERS Provide students with copies of an illustration of a geothermal plant. Engage them in a discussion of how heat flows through the system and where it might be lost.

L3 ADVANCED STUDENTS One version of a geothermal plant, called a binary cycle plant, uses lower temperature water to heat a second fluid with a low boiling point such as butane which actually drives the turbines. Have students research how binary cycle plants operate and what thermodynamic principles they demonstrate during operation. Allow time for students to present their findings to the class.

Answers

TAKE IT FURTHER

1. The system is the building. The surroundings are the hot water and steam below Earth's surface. Heat flows from the surroundings into the system so the process is endothermic.
2. 2.03×10^8 kJ of energy are released.
3. Students should compare the costs and benefits of geothermal energy to another source of energy. Possible sources of energy include nuclear fusion, fossil fuels, oil, solar and wind.

LESSON 17.4

Key Objectives

17.4.1 IDENTIFY two ways that the heat of reaction can be determined when it cannot be directly measured.

17.4 Calculating Heats of Reaction

C.6.3 Heat flow and temperature change problems

CHEMISTRY & YOU

Q: *How much heat is released when a diamond changes into graphite?* Diamonds are gemstones composed of carbon. Over a time period of millions and millions of years, diamond will break down into graphite, which is another form of carbon. How then can you determine the enthalpy change for the reaction?

Key Question

How can you calculate the heat of reaction when it cannot be directly measured?

Vocabulary

- Hess's law of heat summation
- standard heat of formation

Hess's Law

How can you calculate the heat of reaction when it cannot be directly measured?

Sometimes it is hard to measure the enthalpy change for a reaction. The reaction might take place too slowly to measure the enthalpy change, or the reaction might be an intermediate step in a series of reactions. Fortunately, it is possible to determine a heat of reaction indirectly using Hess's law of heat summation. **Hess's law of heat summation** states that if you add two or more thermochemical equations to give a final equation, then you can also add the heats of reaction to give the final heat of reaction. **Hess's law allows you to determine the heat of reaction indirectly by using the known heats of reaction of two or more thermochemical equations.**

Consider the conversion of diamond to graphite, discussed above.

$$C(s, \text{diamond}) \longrightarrow C(s, \text{graphite})$$

Although the enthalpy change for this reaction cannot be measured directly, you can use Hess's law to find the enthalpy change for the conversion of diamond to graphite by using the following combustion reactions and Figure 17.14:

a. $C(s, \text{graphite}) + O_2(g) \longrightarrow CO_2(g)$ $\quad \Delta H = -393.5$ kJ

b. $C(s, \text{diamond}) + O_2(g) \longrightarrow CO_2(g)$ $\quad \Delta H = -395.4$ kJ

Write equation **a** in reverse to give:

c. $CO_2(g) \longrightarrow C(s, \text{graphite}) + O_2(g)$ $\quad \Delta H = 393.5$ kJ

When you write a reverse reaction, you must also change the sign of ΔH. If you add equations **b** and **c,** you get the equation for the conversion of diamond to graphite. The $CO_2(g)$ and $O_2(g)$ terms on both sides of the summed equations cancel. If you also add the values of ΔH for equations **b** and **c,** you get the heat of reaction for this conversion.

$$C(s, \text{diamond}) + \cancel{O_2(g)} \longrightarrow \cancel{CO_2(g)} \quad \Delta H = -395.4 \text{ kJ}$$

$$\cancel{CO_2(g)} \longrightarrow C(s, \text{graphite}) + \cancel{O_2(g)} \quad \Delta H = 393.5 \text{ kJ}$$

$$C(s, \text{diamond}) \longrightarrow C(s, \text{graphite}) \quad \Delta H = -1.9 \text{ kJ}$$

Focus on ELL

1 CONTENT AND LANGUAGE Provide students with a double bubble diagram. On the lines on the outside of each bubble have students write how the two methods of determining the heat of reaction are different and on the lines on the inside of each bubble write how they are similar.

2 FRONTLOAD THE LESSON Ask each student to draw a map from their house to the school using two different routes. Have each student present the two routes and explain the pros and cons of each route. Relate this to the two methods of determining the heats of reaction in the lesson.

3 COMPREHENSIBLE INPUT Explain Figures 17.14–17.15 and read aloud the captions. Provide students with their own copy of the diagrams. As you discuss the questions in the captions, encourage students to take notes directly on the diagram. Assign students to compare the diagrams and to create a summary paragraph explaining what they have learned.

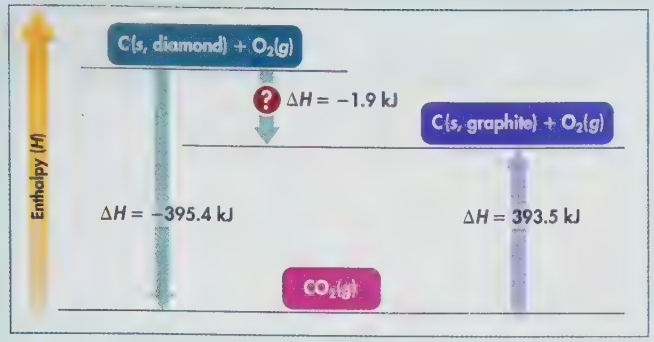

Figure 17.14 Conversion of Diamond to Graphite
Hess's law is used to determine the enthalpy change for the conversion of diamond to graphite.

Go online to see how Hess's law is used.

Another case where Hess's law is useful is when reactions yield products in addition to the product of interest. Suppose you want to determine the enthalpy change for the formation of carbon monoxide from its elements. You can write the following equation for this reaction.

$$C(s, \text{graphite}) + \tfrac{1}{2}O_2(g) \longrightarrow CO(g) \qquad \Delta H = ?$$

Although it is easy to write the equation, carrying out the reaction in the laboratory as written is virtually impossible. Carbon dioxide is produced along with carbon monoxide. Therefore, any measured heat of reaction is related to the formation of both $CO(g)$ and $CO_2(g)$, and not $CO(g)$ alone. However, you can calculate the desired enthalpy change by using Hess's law and the following two reactions that can be carried out in the laboratory:

a. $C(s, \text{graphite}) + O_2(g) \longrightarrow CO_2(g) \qquad \Delta H = -393.5 \text{ kJ}$

b. $CO(g) + \tfrac{1}{2}O_2(g) \longrightarrow CO_2(g) \qquad \Delta H = -283.0 \text{ kJ}$

Writing the reverse of equation **b** yields equation **c.**

c. $CO_2(g) \longrightarrow CO(g) + \tfrac{1}{2}O_2(g) \qquad \Delta H = 283.0 \text{ kJ}$

Adding equations **a** and **c** gives the expression for the formation of $CO(g)$ from its elements. The enthalpy diagram for this heat summation is shown in Figure 17.15. Notice that only $\tfrac{1}{2}O_2(g)$ cancels from each equation.

$$C(s, \text{graphite}) + O_2(g) \longrightarrow \cancel{CO_2(g)} \qquad \Delta H = -393.5 \text{ kJ}$$
$$\cancel{CO_2(g)} \longrightarrow CO(g) + \tfrac{1}{2}O_2(g) \qquad \Delta H = 283.0 \text{ kJ}$$
$$C(s, \text{graphite}) + \tfrac{1}{2}O_2(g) \longrightarrow CO(g) \qquad \Delta H = -110.5 \text{ kJ}$$

CHEMISTRY & YOU

Q: *How can you determine ΔH for the conversion of diamond to graphite without performing the reaction?*

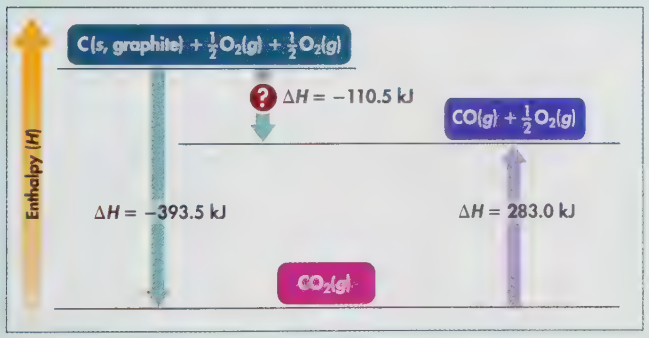

Figure 17.15 Formation of CO(g) From Its Elements
Hess's law is used to determine the enthalpy change for the formation of CO(g) from its elements.
Interpret Diagrams ***How does the diagram represent endothermic and exothermic reactions differently?***

UbD Check for Understanding

How can you determine the amount of energy absorbed or released in a chemical or physical process?

Write the following reactions for the dissociation of sulfuric acid on the board.

$H_2SO_4(l) \rightarrow SO_3(g) + H_2O(g)$

a. $H_2S(g) + 2O_2(g) \rightarrow H_2SO_4(l) \qquad \Delta H = -235.5 \text{ kJ}$

b. $H_2S(g) + 2O_2(g) \rightarrow SO_3(g) + H_2O(l) \qquad \Delta H = -207 \text{ kJ}$

c. $H_2O(l) \rightarrow H_2O(g) \qquad \Delta H = 44 \text{ kJ}$

Assess students' understanding of this Essential Question by asking them to use Hess's law to calculate the enthalpy change for this dissociation. *(Write equation (a) in reverse and change the sign on ΔH to positive. Then add ΔH for the three reactions: 235.5 kJ + (–207 kJ) + 44 kJ = 72kJ)*

Explain

Hess's Law

USE VISUALS Have students examine Figure 17.14. **Ask** What is the enthalpy change of the reverse reaction—from graphite to diamond? Why? *(ΔH = 1.9 kJ, because the enthalpy change for the reverse reaction is equal to the negative ΔH of the forward reaction. The negative of –1.9kJ is 1.9 kJ.)*

USE AN ANALOGY Provide the following analogy for enthalpy change:

A group of hikers is attempting to reach the summit of a mountain. Two routes are possible: one is a short, steep path that goes directly to the top; the other is a long path that is less steep but involves a number of changes in direction. Although the distances of the two routes are different, the final altitude is the same.

Explain that the change in altitude is analogous to the enthalpy change for a reaction. The distances traveled by the hikers on each path is analogous to the number of steps required to form a given set of products. No matter how one goes from a given set of reactants to a given set of products, in one step or in several, the overall enthalpy change is the same.

CHEMISTRY & YOU You can use Hess's Law.

Explain

USE VISUALS Have students study Figure 17.15. **Ask** How can you tell from the diagram that the formation of CO is exothermic? *(The arrow points downward and ΔH is negative.)*

Extend

Connect to GEOLOGY

Explain that diamonds are made almost entirely of carbon, and are the world's oldest substance. At 3.3 billion years of age, they are almost as old as Earth itself. Guide students to understand that diamonds only form under extremely intense temperature and pressure. Explain that the only place on Earth these conditions are found naturally is 100 miles underground. **Ask** Why are diamonds discovered after a volcanic eruption? *(The eruption lifts diamonds and other minerals to the surface.)*

Answers

FIGURE 17.15 The arrow points downward for an exothermic reaction and upward for an endothermic reaction.

Explain

Standard Heats of Formation

USE VISUALS Display Table 17.4 on an overhead projector. Define *standard heat of formation* as the change in enthalpy that accompanies the formation of 1 mole of a compound from its elements with all substances in their standard states at 25°C and 101.3 kPa. Point out that the standard heat of formation of a free element in its standard state is defined as 0. Demonstrate how to use standard heats of formation to calculate heats of reaction at standard conditions.

USE VISUALS Have students study Figure 17.16. **Ask** Does water have a lower or higher enthalpy than the elements from which it is formed? *(lower)* **Ask** On what other basis can you account for your answer? *(It takes energy to decompose water.)*

Table 17.4

Standard Heats of Formation ($\Delta H_f°$) at 25°C and 101.3 kPa

Substance	$\Delta H_f°$ (kJ/mol)	Substance	$\Delta H_f°$ (kJ/mol)	Substance	$\Delta H_f°$ (kJ/mol)

Standard Heats of Formation

How can you calculate the heat of reaction when it cannot be directly measured?

Enthalpy changes generally depend on conditions of the process. To compare enthalpy changes, scientists specify a common set of conditions as a reference point. These conditions, called the standard state, refer to the stable form of a substance at 25°C and 101.3 kPa. The **standard heat of formation** ($\Delta H_f°$) of a compound is the change in enthalpy that accompanies the formation of one mole of a compound from its elements with all substances in their standard states. The $\Delta H_f°$ of a free element in its standard state is arbitrarily set at zero. Thus, $\Delta H_f° = 0$ for the diatomic molecules $H_2(g)$, $N_2(g)$, $O_2(g)$, $F_2(g)$, $Cl_2(g)$, $Br_2(l)$, and $I_2(s)$. Similarly, $\Delta H_f° = 0$ kJ/mol for the graphite form of carbon, $C(s,$ graphite$)$. Table 17.4 lists $\Delta H_f°$ values for some common substances.

Standard heats of formation provide an alternative to Hess's law in determining heats of reaction indirectly. **For a reaction that occurs at standard conditions, you can calculate the heat of reaction by using standard heats of formation.** Such an enthalpy change is called the standard heat of reaction ($\Delta H°$). The standard heat of reaction is the difference between the standard heats of formation of all the reactants and products.

$$\Delta H° = \Delta H_f°\ (\text{products}) - \Delta H_f°\ (\text{reactants})$$

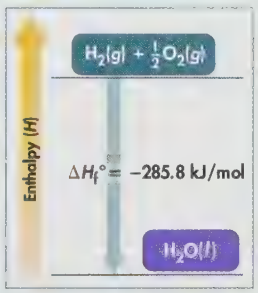

Figure 17.16 Standard Heat of Formation of Water
This enthalpy diagram shows the standard heat of formation of water.
Classify *Is the reaction endothermic or exothermic?*

Figure 17.16 is an enthalpy diagram for the formation of water from its elements at standard conditions. The enthalpy difference between the reactants and products, −285.8 kJ/mol, is the standard heat of formation of liquid water from the gases hydrogen and oxygen. Notice that water has a lower enthalpy than the elements from which it is formed.

Differentiated Instruction

L1 STRUGGLING STUDENTS If students are having trouble visualizing the application of Hess's law, give them the following simplified equations.

$1 + 2 \rightarrow 3$

$3 + 4 \rightarrow 5 + 2$

Show students how 2 and 3 can be cancelled from both sides of the equations. The two equations can then be added together to produce $1 + 4 \rightarrow 5$.

L1 SPECIAL NEEDS STUDENTS When assessing students, have them give a thumbs up or a nod when they want to keep an enthalpy value the same, and a thumbs down or a head shake to indicate that they want to change the sign on the enthalpy value.

L3 ADVANCED STUDENTS Tell students to prepare a 10 minute lesson on Hess's Law directed to struggling students. Tell students to use an analogy, such as moving a ball down a football field or soccer field, to visually explain the concept.

Sample Problem 17.8

Calculating the Standard Heat of Reaction

What is the standard heat of reaction ($\Delta H°$) for the reaction of $CO(g)$ with $O_2(g)$ to form $CO_2(g)$?

1 Analyze **List the knowns and the unknown.** Balance the equation of the reaction of $CO(g)$ with $O_2(g)$ to form $CO_2(g)$. Then determine $\Delta H°$ using the standard heats of formation of the reactants and products.

KNOWNS
(from Table 17.4)
$\Delta H_f°CO(g) = -110.5$ kJ/mol
$\Delta H_f°O_2(g) = 0$ kJ/mol (free element)
$\Delta H_f°CO_2(g) = -393.5$ kJ/mol

UNKNOWN
$\Delta H° = ?$ kJ

2 Calculate **Solve for the unknown.**

First, write the balanced equation.

$$2CO(g) + O_2(g) \longrightarrow 2CO_2(g)$$

Find and add $\Delta H_f°$ of all of the reactants.

$$\Delta H_f°(\text{reactants}) = 2 \text{ mol } CO(g) \times \Delta H_f°CO(g) + 1 \text{ mol } O_2(g) \times \Delta H_f°O_2(g)$$
$$= 2 \text{ mol } CO(g) \times \frac{-110.5 \text{ kJ}}{1 \text{ mol } CO(g)} + 1 \text{ mol } O_2(g) \times \frac{0 \text{ kJ}}{1 \text{ mol } O_2(g)}$$
$$= -221.0 \text{ kJ}$$

Remember to take into account the number of moles of each reactant and product.

Find $\Delta H_f°$ of the product in a similar way.

$$\Delta H_f°(\text{products}) = 2 \text{ mol } CO_2(g) \times \Delta H_f°CO_2(g)$$
$$= 2 \text{ mol } CO_2(g) \times \frac{-393.5 \text{ kJ}}{1 \text{ mol } CO_2(g)}$$
$$= -787.0 \text{ kJ}$$

Calculate $\Delta H°$ for the reaction.

$$\Delta H° = \Delta H_f°(\text{products}) - \Delta H_f°(\text{reactants})$$
$$= (-787.0 \text{ kJ}) - (-221.0 \text{ kJ})$$
$$= -566.0 \text{ kJ}$$

3 Evaluate **Does the result make sense?** The $\Delta H°$ is negative, so the reaction is exothermic. This outcome makes sense because combustion reactions always release heat.

35. Calculate $\Delta H°$ for the following reaction:

$$Br_2(g) \longrightarrow Br_2(l)$$

Remember, $Br_2(l)$ is a free element.

36. What is the standard heat of reaction ($\Delta H°$) for the formation of $NO_2(g)$ from $NO(g)$ and $O_2(g)$?

To do Problem 36, first write the balanced equation for the reaction.

Foundations for Math

COEFFICIENTS When calculating standard heats of reaction, the number of moles of each reactant and product must be taken into account. Remind students that standard heats of formation have units of kJ/mol, but that the heat of reaction has units of kJ. Thus, they must account for the number of moles of each reactant and each product in their calculations in order to obtain answers with units of kJ.

In **Sample Problem 17.8,** there are 2 mol CO, 1 mol O_2, and 2 mol CO_2. Point out that the standard heat of formation for each compound is multiplied by the number of moles of the compound to determine the total heat of formation for that compound in the reaction.

Extend

Connect to ENGINEERING

In this thermite reaction, iron(III) oxide is reduced to metallic iron by aluminum.

$$Fe_2O_3(s) + 2Al(s) \rightarrow 2Fe(s) + Al_2O_3(s)$$
$$\Delta H = -853.9 \text{ kJ}$$

The reaction reaches a temperature of about 3000°C. **Ask** students to research the resulting products of this reaction and describe the condition of each. ($mp_{Fe} = 1530°C$; $mp_{soln} = 2030°C$). *(The products are iron and aluminum oxide, and are molten.)*

Sample Practice Problem

Calculate the standard heat of reaction for the following reaction:

$$2SO_2(g) + O_2(g) \rightarrow 2SO_3(g)$$
(–197.8 kJ)

Answers

FIGURE 17.16 exothermic

Informal Assessment

Have students explain two ways that scientists can determine the heat of a reaction indirectly. Encourage students to use examples, symbols, and/or diagrams in their explanations. *(1. Add two or more thermochemical equations to give the desired equation. 2. Find the difference between the standard heats of formation for all reactants and the standard heats of formation for all products in the reaction.)* Then direct students to complete 17.4 Lesson Check.

Reteach

Write an overall reaction on the board, using compounds found in Table 17.4. Challenge students to identify the reaction steps, if any, needed to account for the enthalpy change. Then, have students use Hess's law of heat summation and the standard heats of formation to indirectly determine the enthalpy change for the reaction.

Answers

FIGURE 17.17 It shows the summation of thermochemical equations to give a final equation. It also shows the enthalpy change for each step.

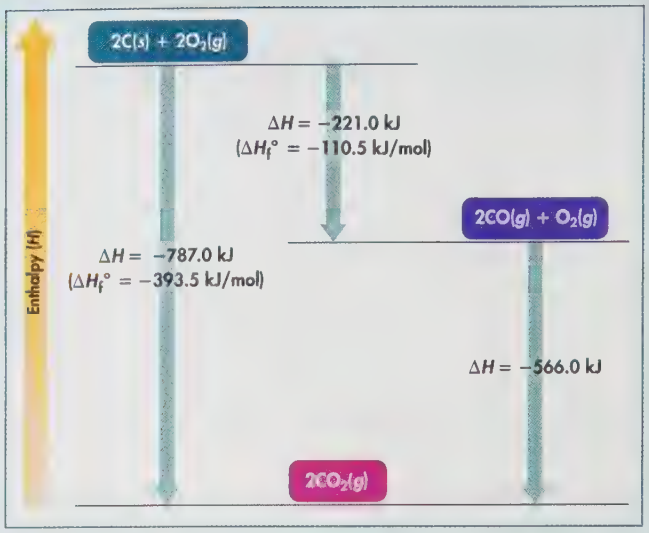

Figure 17.17 Reaction of Carbon Monoxide and Oxygen
Standard heats of formation are used to calculate the enthalpy change for the reaction of carbon monoxide and oxygen.
Explain ***How does this diagram also demonstrate Hess's law?***

Figure 17.17 is an enthalpy diagram that shows how the standard heat of reaction was calculated in Sample Problem 17.8.

$$2CO(g) + O_2(g) \longrightarrow 2CO_2(g)$$

The standard heat of formation of the product, $CO_2(g)$, is −393.5 kJ/mol. The standard heats of formation of the reactants, $CO(g)$ and $O_2(g)$, are −110.5 kJ/mol and 0 kJ/mol, respectively. The diagram shows the difference between ΔH_f°(product) and ΔH_f°(reactants) after taking into account the number of moles of each.

17.4 LessonCheck

37. Describe What are two ways the heat of reaction can be determined when it cannot be directly measured?

38. Calculate What is the enthalpy change (ΔH) in kJ for the following reaction?

$$2Al(s) + Fe_2O_3(s) \longrightarrow 2Fe(s) + Al_2O_3(s)$$

Use the enthalpy changes for the combustion of aluminum and iron:

$$2Al(s) + \tfrac{3}{2}O_2(g) \longrightarrow Al_2O_3(s) \quad \Delta H = -1676.0 \text{ kJ}$$
$$2Fe(s) + \tfrac{3}{2}O_2(g) \longrightarrow Fe_2O_3(s) \quad \Delta H = -822.1 \text{ kJ}$$

39. Explain How can you calculate the standard heat of reaction?

40. Calculate What is the standard heat of reaction (ΔH°) for the decomposition of hydrogen peroxide?

$$2H_2O_2(l) \longrightarrow 2H_2O(l) + O_2(g)$$

BIG IDEA MATTER AND ENERGY

41. Use Hess's law and two thermochemical equations on page R34 to calculate ΔH for the following reaction:

$$2H_2O(g) + CH_4(g) \longrightarrow CO_2(g) + 4H_2(g)$$

Small-Scale Lab

Heat of Combustion of a Candle

Purpose

To observe a burning candle and calculate the heat associated with the combustion reaction

Materials

- ruler
- candle
- aluminum foil
- balance
- safety matches

Procedure

1. Measure and record the length of a candle in centimeters.

2. Place the candle on a small piece of aluminum foil and measure the mass of the foil-candle system.

3. Note the time as you light the candle. Let the candle burn for about five minutes.
CAUTION *Keep clothing away from the flame.* While you wait, begin answering the Analyze and Conclude questions.

4. Extinguish the candle and record the time.

5. Measure the mass of the foil-candle system again. **DO NOT** try to measure the mass while the candle is burning.

Analyze and Conclude

1. Observe While the candle is burning, draw a picture of what you see.

2. Observe Examine the flame closely. Is it the wax or the wick that burns?

3. Infer If you said the wax, how does the wax burn without touching the flame? If you said the wick, what is the function of the wax?

4. Analyze Data If you could measure the temperature near the flame, you would find that the air is much hotter above the flame than it is beside it. Why?

5. Draw Conclusions How much length and mass did the candle lose? Are these data more consistent with the wax or the wick burning?

6. Infer Keeping in mind that *wick* is also a verb, explain how a candle works.

7. Describe The formula for candle wax can be approximated as $C_{20}H_{42}$. Write a balanced equation for the complete combustion of candle wax.

8. Calculate Determine the number of moles of candle wax burned in the experiment.

9. Calculate What is the heat of combustion of candle wax in kJ/mol? The standard heat of formation of candle wax ($C_{20}H_{42}$) is −2230 kJ/mol. The standard heats of formation of carbon dioxide gas and liquid water are −394 kJ/mol and −286 kJ/mol, respectively.

10. Calculate Determine the amount of heat (in kJ) released in your reaction. (*Hint:* Multiply the number of moles of candle wax burned in the experiment by the heat of combustion of candle wax.)

You're the Chemist

1. Design an Experiment Design an experiment to show that the candle wax does not burn with complete combustion.

2. Design an Experiment Design an experiment to show that water is a product of the combustion of a candle.

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the Lab. Make sure each group has ELLs of varied language proficiencies, so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Break the procedure down into simpler bulleted steps.

INTERMEDIATE: LOW/HIGH Simplify the wording of the Analyze and Conclude questions. Convert multi-part questions into multiple questions.

ADVANCED: LOW/HIGH Pair students with writing partners to write their lab reports. Have partners evaluate each other's reports and provide feedback for revisions.

Small-Scale Lab

OBJECTIVE After completing this activity, students will be able to explore the way a candle burns. They will also be able to apply basic principles of thermochemistry to the combustion reaction and calculate the heat of combustion.

MISCONCEPTION ALERT Students have many misconceptions about the way candles burn. Questions 1 and 2 prompt students to wrongly conclude that the wick burns and the wax just slows the rate of burning. Questions 5 and 6 focus students on the key experiment, the determination of the mass loss of the candle, and allow them to revise their opinions.

PREP TIME 10 minutes

CLASS TIME 20 minutes

MATERIALS candle, metric ruler, aluminum foil, balance, safety matches, clock or watch, temperature probe (optional)

ADVANCE PREPARATION Purchase or collect candles and a roll of aluminum foil.

SAFETY Remind students to wear safety glasses and to keep the flame away from any combustible material.

TEACHING TIPS For best results and greater safety, use short, stout votive candles. The day before the lab, remind students to tie long hair back and to avoid wearing loose-sleeved clothes.

EXPECTED OUTCOME The candle loses mass and length as it burns.

ANALYZE AND CONCLUDE

1. Drawings should show the wax melting.
2. Many students incorrectly choose the wick.
3. The wick draws melted wax to the flame. Those who think the wick burns may suggest that the wax slows the rate of burning.
4. The hot gases expand and rise.
5. A few millimeters and a few tenths of a gram are reasonable answers. The mass loss is consistent with burning wax.
6. Heat from the combustion melts wax, which is drawn up by the wick, evaporated, and burned.
7. $C_{20}H_{42} + \frac{61}{2} O_2 \longrightarrow 20CO_2 + 21H_2O$
8. Sample answer: 0.0018 mol
9. Sample Answer: –11,700 kJ/mol
10. Sample Answer: 21 kJ

YOU'RE THE CHEMIST

1. Soot will appear on a glass Petri dish held over the flame.
2. Water will condense on the bottom of an ice-filled, glass Petri dish held over the flame.

FOR ENRICHMENT Have students design an experiment to determine the heat of combustion of table sugar. This is a reaction that you might wish to demonstrate for the class.

STUDY GUIDE

Evaluate

Review and Assessment Materials

WALK-THRU TUTORIALS Each of the Math Tune-Up problems on the following page has an animated step-by-step tutorial that explains the problem-solving strategy in detail.

PROBLEM SETS Have students practice more chemical quantity problems by using the Chapter 17 Online Problem Set.

MATH SKILLS REVIEW Have struggling students practice solving algebraic equations by using the MathXL learning module.

VIRTUAL LABS Have students complete a virtual lab as an in-class or take-home assignment to help reinforce the mathematical relationships involved in calculating calculating enthalpy changes.

Study Tip

STUDY WITH FRIENDS Divide the class into small groups, and **ask** each group to write a review question for each Key Concept and each vocabulary term in one of the sections of the chapter. When students have finished writing their questions, have the groups place their lists in a central location. Then, **ask** each group to pick up a list of questions for one of the other three sections. After groups have had a chance to collaborate on answering the questions, repeat the process, with groups answering the questions for a third and fourth section.

17 Study Guide

BIG IDEA MATTER AND ENERGY

During a chemical or physical process, the energy of the universe is conserved. If energy is absorbed by the system in a chemical or physical process, the same amount of energy is released by the surroundings. Conversely, if energy is released by the system, the same amount of energy is absorbed by the surroundings. The heat of reaction or process can be determined experimentally through calorimetry. The heat of reaction can also be calculated by using the known heats of reaction of two or more thermochemical equations or by using standard heats of formation.

17.1 The Flow of Energy

- Energy changes occur as either heat transfer or work, or a combination of both.
- During any chemical or physical process, the energy of the universe remains unchanged.
- The heat capacity of an object depends on both its mass and its chemical composition.

- thermochemistry (556)
- chemical potential energy (556) • heat (556)
- system (557) • surroundings (557)
- law of conservation of energy (557)
- endothermic process (557)
- exothermic process (557)
- heat capacity (559) • specific heat (559)

Key Equation

$$C = \frac{q}{m \times \Delta T}$$

17.2 Measuring and Expressing Enthalpy Changes

- The value of ΔH of a reaction can be determined by measuring the heat flow of the reaction at constant pressure.
- In a chemical equation, the enthalpy change for the reaction can be written as either a reactant or a product.

- calorimetry (562)
- calorimeter (562)
- enthalpy (562)
- thermochemical equation (565)
- heat of reaction (565)
- heat of combustion (568)

Key Equation

$$q_{sys} = \Delta H = -q_{surr} = -m \times C \times \Delta T$$

17.3 Heat in Changes of State

- The quantity of heat absorbed by a melting solid is exactly the same as the quantity of heat released when the liquid solidifies; that is, $\Delta H_{fus} = -\Delta H_{solid}$.
- The quantity of heat absorbed by a vaporizing liquid is exactly the same as the quantity of heat released when the vapor condenses; that is, $\Delta H_{vap} = -\Delta H_{cond}$.
- During the formation of a solution, heat is either released or absorbed.

- molar heat of fusion (569)
- molar heat of solidification (569)
- molar heat of vaporization (571)
- molar heat of condensation (572)
- molar heat of solution (574)

17.4 Calculating Heats of Reaction

- Hess's law allows you to determine the heat of reaction indirectly by using the known heats of reaction of two or more thermochemical equations.
- For a reaction that occurs at standard conditions, you can calculate the heat of reaction by using standard heats of formation.

- Hess's law of heat summation (578)
- standard heat of formation (580)

Key Equation

$$\Delta H^\circ = \Delta H_f^\circ(\text{products}) - \Delta H_f^\circ(\text{reactants})$$

UbD Understanding by Design

Performance Tasks

CHILLING OUT Research the mechanism used in refrigerators and freezers to keep food cold. Create a flowchart that illustrates and explains the heat transfer processes and direction of heat flow that occurs between the refrigerator and its contents. Include an explanation of how frost-free units prevent a build-up of frost in the freezer compartment. The flowchart should document all relevant enthalpy changes.

HOT AND COLD PACKS Have students design and perform an experiment that measures the temperature change in a hot or cold pack. Consider changing the solute to a compound not mentioned in the Lesson 17.3 (e.g., sodium acetate) and have students conclude whether the solution process is endothermic or exothermic.

Math Tune-Up: Calculating Enthalpy Changes

Problem	❶ Analyze	❷ Calculate	❸ Evaluate
When 75.0 mL of water containing 0.100 mol HCl at 21.0°C is added to 75.0 mL of water containing 0.100 mol NaOH at 21.0°C in a foam cup calorimeter, the temperature of the solution increases to 29.6°C. Calculate the enthalpy change (in kJ) during this reaction.	Knowns: $C_{water} = 4.18\ J/(g{\cdot}°C)$ $V_{final} = V_{HCl} + V_{NaOH}$ $= 75.0\ mL + 75.0\ mL$ $= 150.0\ mL$ $\Delta T = T_f - T_i$ $= 29.6°C - 21.0°C$ $= 8.6°C$ $density_{solution} = 1.00\ g/mL$ Unknown: $\Delta H = ?\ kJ$ Use $\Delta H = -q_{surr}$ $= -m \times C \times \Delta T$	Calculate the mass of water. $m_{water} = 150.0\ \cancel{mL} \times \frac{1.00\ g}{1\ \cancel{mL}}$ $= 150.0\ g$ Use the values for m_{water}, C_{water}, and ΔT to calculate ΔH. $\Delta H = -(150.0\ \cancel{g})(4.18\ J/(\cancel{g}{\cdot}°\cancel{C})) \times (8.6\cancel{°C})$ $= -5400\ J$ $\Delta H = -5.4\ kJ$	About 4 J of heat raises the temperature of 1 g of water 1°C, so 600 J of heat is required to raise the temperature of 150 g of water 1°C. To heat 150 g of water 9°C requires about 5400 J, or 5.4 kJ. *Note: For reactions in aqueous solutions, you can assume that the densities of the solutions are 1.00 g/mL.*
How much heat is absorbed when 54.9 g $H_2O(l)$ at 100°C and 101.3 kPa is converted to $H_2O(g)$ at 100°C?	Knowns: Initial and final conditions are 100°C and 101.3 kPa mass of liquid water converted to steam = 54.9 g $\Delta H_{vap} = 40.7\ kJ/mol$ Unknown: $\Delta H = ?\ kJ$ Refer to the thermochemical equation $H_2O(l) + 40.7\ kJ \longrightarrow H_2O(g)$	The required conversion factors come from the molar mass of water and ΔH_{vap}. $\frac{1\ mol\ H_2O(l)}{18.0\ g\ H_2O(l)}$ and $\frac{40.7\ kJ}{1\ mol\ H_2O(l)}$ Multiply the mass of water by the conversion factors. $\Delta H = 54.9\ \cancel{g\ H_2O(l)} \times \frac{1\ \cancel{mol\ H_2O(l)}}{18.0\ \cancel{g\ H_2O(l)}} \times \frac{40.7\ kJ}{1\ \cancel{mol\ H_2O(l)}}$ $\Delta H = 124\ kJ$	Knowing the molar mass of water is 18.0 g/mol, 54.9 g $H_2O(l)$ is about 3 mol H_2O. The calculated enthalpy change should be about $3\ \cancel{mol} \times 40\ kJ/\cancel{mol} = 120\ kJ$, and it is.
What is the standard heat of reaction ($\Delta H°$) for the reaction of $SO_2(g)$ with $O_2(g)$ to form $SO_3(g)$?	Knowns: (from Table 17.4) $\Delta H_f°SO_2(g) = -296.8\ kJ/mol$ $\Delta H_f°O_2(g) = 0\ kJ/mol$ $\Delta H_f°SO_3(g) = -395.7\ kJ/mol$ Unknown: $\Delta H° = ?\ kJ$ Use the standard heats of formation for the reactants and products to calculate $\Delta H°$. $\Delta H° = \Delta H_f°(products) - \Delta H_f°(reactants)$	Write the balanced equation. $2SO_2(g) + O_2(g) \longrightarrow 2SO_3(g)$ Find $\Delta H_f°$ of the reactants. $\Delta H_f°(reactants) = 2\ \cancel{mol\ SO_2(g)} \times \frac{-296.8\ kJ}{1\ \cancel{mol\ SO_2(g)}} + 0\ kJ = -593.6\ kJ$ Find $\Delta H_f°$ of the product. $\Delta H_f°(product) = 2\ \cancel{mol\ SO_3(g)} \times \frac{-395.7\ kJ}{1\ \cancel{mol\ SO_3(g)}} = -791.4\ kJ$ Calculate $\Delta H°$ for the reaction. $\Delta H° = (-791.4\ kJ) - (-593.6\ kJ)$ $\Delta H° = -197.8\ kJ$	The $\Delta H°$ is negative, so the reaction is exothermic. This makes sense because combustion reactions always release heat. *Remember: The $\Delta H_f°$ of a free element in its standard state is 0.*

Focus on ELL

5 ASSESS UNDERSTANDING Assess students using a portfolio for this chapter. Include various types of learning assignments based on the student's language proficiency.

BEGINNING: LOW Include models or pictures of models, lists, or diagrams created by the student.

HIGH Include copies of the graphic organizers used to take notes or show how concepts are related.

INTERMEDIATE: LOW Include any predictions made on the topic of lessons or pre-reading and the result of those predictions.

HIGH Include any lab write-ups that were assigned during the chapter.

ADVANCED: LOW/HIGH Include an essay that explains why freezing can protect a citrus tree.

Math Review

Example and sample practice problems related to calculating enthalpy changes can be found on the following pages:

LESSON 17.1 Calculating the Specific Heat of a Metal—page 561

LESSON 17.2 Enthalpy Change in a Calorimetry Experiment—page 564; Using the Heat of Reaction to Calculate Enthalpy Change—page 567

Answers

LESSON 17.1

42. Chemical potential energy is energy stored in a substance because of its chemical composition.

43. Heat flows from the object at the higher temperature to the object at the lower temperature. For example, holding a cold soft-drink can makes your hand cold.

44. Answers will vary, but should mention that thermochemistry measures heat flow across the boundary between the system and the surroundings.

45. Answers will vary, but should include the idea that energy is conserved in every physical and chemical process.

46. In an endothermic process, the system absorbs heat from the surroundings. In an exothermic process, the system releases heat to the surroundings.

47. **a.** exothermic
b. The immediate surroundings are the glass beaker and the air. If one or more of the substances is in water, the water is also considered part of the surroundings.

48. **a.** exothermic **b.** endothermic
c. exothermic **d.** endothermic

49. A negative sign is given to heat flow from the system to the surroundings. A positive sign is given to heat flow to the system from the surroundings.

50. 1 Cal = 1000 cal = 1 kcal

51. **a.** 0.85 Cal
b. 1.86×10^3 J
c. 1.8×10^3 J
d. 1.1×10^2 cal

52. the chemical composition of the substance and its mass

53. 4.3×10^3 J

LESSON 17.2

54. The heat released by a system is equal to the heat absorbed by its surroundings. The heat absorbed by a system is equal to the heat released by its surroundings.

55. A calorimeter is an instrument used to measure enthalpy changes in physical or chemical processes.

56. enthalpy

57. bomb calorimeter

58. amount of heat released or absorbed in a chemical change at constant pressure

59. -4.5×10^2 KJ

60. one atmosphere pressure (101.3 kPa); all reactants and products in their normal physical state at 25°C.

17 Assessment

* Solutions appear in Appendix E

Lesson by Lesson

17.1 The Flow of Energy

42. Define *chemical potential energy.*

43. What always happens when two objects of different temperatures come in contact? Give an example from your own experience.

44. Why do you think it is important to define the system and the surroundings?

45. Explain in your own words the law of conservation of energy.

46. How do endothermic processes differ from exothermic processes?

***47.** Two substances in a glass beaker chemically react, and the beaker becomes too hot to touch.
a. Is the reaction endothermic or exothermic?
b. If the two substances are defined as the system, what constitutes the surroundings?

***48.** Classify these processes as endothermic or exothermic.
a. condensing steam
b. evaporating alcohol
c. burning alcohol
d. baking a potato

49. Describe the sign convention that is used when describing heat flow in a system.

50. What is the relationship between a calorie and a Calorie?

***51.** Make the following conversions.
a. 8.50×10^2 cal to Calories
b. 444 cal to joules
c. 1.8 kJ to joules
d. 4.5×10^{-1} kJ to calories

52. What factors determine the heat capacity of an object?

***53.** How much heat is required to raise the temperature of 400.0 g of silver 45°C?

17.2 Measuring and Expressing Enthalpy Changes

54. Calorimetry is based on what basic concepts?

55. What is the function of a calorimeter?

56. What is the property that describes heat change at constant pressure?

57. What device would you use to measure the heat released at constant volume?

58. What information is given in a thermochemical equation?

***59.** The burning of magnesium is a highly exothermic reaction.

$$2Mg(s) + O_2(g) \longrightarrow 2MgO(s) + 1204\ kJ$$

How many kilojoules of heat are released when 0.75 mol of Mg burn in an excess of O_2?

60. Give the standard conditions for heat of combustion.

17.3 Heat in Changes of State

61. Explain why ice melts at 0°C without an increase of temperature, even though heat flows from the surroundings to the system (the ice).

***62.** Calculate the quantity of heat gained or lost in the following changes:
a. 3.50 mol of water freezes at 0°C
b. 0.44 mol of steam condenses at 100°C
c. 1.25 mol NaOH(*s*) dissolves in water
d. 0.15 mol $C_2H_6O(l)$ vaporizes at 78.3°C

63. Sodium ethanoate dissolves readily in water according to the following equation:

$$NaC_2H_3O_2(s) \longrightarrow NaC_2H_3O_2(aq)$$
$$\Delta H = -17.3\ kJ/mol$$

Would this process increase or decrease the temperature of the water?

17.4 Calculating Heats of Reaction

64. Explain Hess's law of heat summation.

***65.** A considerable amount of heat is required for the decomposition of aluminum oxide.

$$2Al_2O_3(s) \longrightarrow 4Al(s) + 3O_2(g)$$
$$\Delta H = 3352\ kJ$$

a. What is the enthalpy change for the formation of 1 mol of aluminum oxide from its elements?
b. Is the reaction endothermic or exothermic?

LESSON 17.3

61. Heat is being used to melt the ice.

62. **a.** –21.0 kJ
b. –18 kJ
c. –55.6 kJ
d. 6.5 kJ

63. increase

LESSON 17.4

64. Hess's law allows the calculation of the enthalpy change of a reaction from the known enthalpy changes of two or more other reactions.

65. **a.** 1676 kJ **b.** ΔH is positive so the reaction is endothermic.

*66. Calculate the enthalpy change for the formation of lead(IV) chloride by the reaction of lead(II) chloride with chlorine.

$$PbCl_2(s) + Cl_2(g) \longrightarrow PbCl_4(l)$$
$$\Delta H = ?$$

Use the following thermochemical equations:

$$Pb(s) + 2Cl_2(g) \longrightarrow PbCl_4(l)$$
$$\Delta H = -329.2 \text{ kJ}$$
$$Pb(s) + Cl_2(g) \longrightarrow PbCl_2(s)$$
$$\Delta H = -359.4 \text{ kJ}$$

67. What is the standard heat of formation of a compound?

68. What is the standard heat of formation of a free element in its standard state?

Understand Concepts

69. How many kilojoules of heat are absorbed when 1.00 L of water is heated from 18°C to 85°C?

*70. Equal masses of two substances absorb the same amount of heat. The temperature of substance A increases twice as much as the temperature of substance B. Which substance has the higher specific heat? Explain.

71. Identify each enthalpy change by name and classify each change as endothermic or exothermic.

a. 1 mol $C_3H_8(l) \longrightarrow$ 1 mol $C_3H_8(g)$
b. 1 mol $Hg(l) \longrightarrow$ 1 mol $Hg(s)$
c. 1 mol $NH_3(g) \longrightarrow$ 1 mol $NH_3(l)$
d. 1 mol $NaCl(s)$ + 3.88 kJ $\longrightarrow$ 1 mol $NaCl(aq)$
e. 1 mol $NaCl(s) \longrightarrow$ 1 mol $NaCl(l)$

72. Name at least three sources of error in experiments that use foam cups as calorimeters.

73. Calculate the enthalpy change in calories when 45.2 g of steam at 100°C condenses to water at the same temperature. What is the enthalpy change in joules?

*74. A 1.55-g piece of stainless steel absorbs 141 J of heat when its temperature increases by 178°C. What is the specific heat of the stainless steel?

75. With one exception, the standard heats of formation of $Na(s)$, $O_2(g)$, $Br_2(l)$, $CO(g)$, $Fe(s)$, and $He(g)$ are identical. What is the exception?

*76. Calculate the change in enthalpy (in kJ) for the following reactions using standard heats of formation ($\Delta H_f°$):

a. $CH_4(g) + \frac{3}{2}O_2(g) \longrightarrow CO(g) + 2H_2O(l)$
b. $2CO(g) + O_2(g) \longrightarrow 2CO_2(g)$

77. The amounts of heat required to change different quantities of carbon tetrachloride, $CCl_4(l)$, into vapor are given in the table.

Mass of CCl_4 (g)	Heat (J)	Heat (cal)
2.90	652	156
7.50	1689	404
17.0	3825	915
26.2	5894	1410
39.8	8945	2140
51.0	11453	2740

a. Graph the data, using heat as the dependent variable.
b. What is the slope of the line?
c. The heat of vaporization of $CCl_4(l)$ is 53.8 cal/g. How does this value compare with the slope of the line?

*78. Find the enthalpy change for the formation of phosphorus pentachloride from its elements.

$$2P(s) + 5Cl_2(g) \longrightarrow 2PCl_5(s)$$

Use the following thermochemical equations:

$$PCl_5(s) \longrightarrow PCl_3(g) + Cl_2(g)$$
$$\Delta H = 156.5 \text{ kJ}$$
$$2P(s) + 3Cl_2(g) \longrightarrow 2PCl_3(g)$$
$$\Delta H = -574.0 \text{ kJ}$$

79. Use standard heats of formation ($\Delta H_f°$) to calculate the change in enthalpy for these reactions.

a. $2C(s, \text{graphite}) + O_2(g) \longrightarrow 2CO(g)$
b. $2H_2O_2(l) \longrightarrow 2H_2O(l) + O_2(g)$
c. $4NH_3(g) + 5O_2(g) \longrightarrow 4NO(g) + 6H_2O(g)$
d. $CaCO_3(s) \longrightarrow CaO(s) + CO_2(g)$

80. The molar heat of vaporization of ethanol, $C_2H_6O(l)$, is 38.6 kJ/mol. Calculate the heat required to vaporize 25.0 g of ethanol at its boiling point.

66. $\Delta H = 30.2$ kJ
67. the change in enthalpy that accompanies the formation of 1 mole of a compound from its elements with all substances in their standard states at 25°C and 101.3 kPa.
68. zero

UNDERSTAND CONCEPTS

69. 281 kJ
70. Substance B; For equal masses, the substance with the greater heat capacity undergoes the smaller temperature change.
71. a. molar heat of vaporization; endothermic
    b. molar heat of solidification; exothermic
    c. molar heat of condensation; exothermic
    d. molar heat of solution; endothermic
    e. molar heat of fusion; endothermic
72. The foam cup will absorb heat. Some heat will be lost to the air. If the reactants are not completely mixed, temperature measurements will not be accurate.
73. 2.44×10^4 cal; 1.02×10^5 J
74. 0.511 J/(g · °C)
75. $CO(g)$
76. a. –607.2 kJ
    b. –566.0 kJ
77. a. Graphs should show the mass on the *x*-axis and heat (in calories) on the *y*-axis.
    b. about 54 cal/g
    c. The two values are essentially the same.
78. $\Delta H = -750$ kJ
79. a. -2.21×10^2 kJ
    b. -1.96×10^2 kJ
    c. -9.046×10^2 kJ
    d. 178.4 kJ
80. 21.0 kJ

ASSESSMENT

Evaluate

Answers

81. 1.41×10^3 g
82. 2.4×10^3 kJ
83. 1.8×10^2 kJ
84. 67.1 kJ
85. 9.6×10^2 g

THINK CRITICALLY

86. Your fingers feel cold because heat always passes from a warmer object (fingers) to a cooler object (ice).
87. **a.** 1.5×10^2 kJ
b. The refrigerator absorbs 1.5×10^2 kJ of heat.
c. assumes the mineral water has the same specific heat as chemically pure water, that no heat is lost by the refrigerator, and the volume of the water is exactly 2 L
88. The statement is true, since stability implies lower energy. The greater the release of heat, the more stable is the compound relative to its elements (all of which have $\Delta H_f^0 = 0$)
89. **a.** −184.76 kJ
b. −138.6 kJ
c. −46.19 kJ
90. When a solid reaches its melting point, additional heat must be absorbed to convert it to a liquid. Therefore, fusion of a solid is endothermic. This heat of fusion is released when a liquid freezes, so freezing is exothermic.
91. **a.** 1.34×10^4 J, 3.21×10^3 cal, 3.21 kcal
b. 128 g H_2O
92. When the vapor condenses to a liquid, the heat of vaporization is released. Therefore, the energy content of the vapor must have been higher than that of the liquid. The statement should state, "The energy content of a substance is higher in the vapor phase than in the liquid phase at the same temperature."
93. −1207 kJ
94. −2820 kJ

*81. An orange contains 106 Calories. What mass of water could this same amount of energy raise from 25.0°C to the boiling point?

82. The combustion of ethene (C_2H_4) is an exothermic reaction.

$$C_2H_4(g) + 3O_2(g) \longrightarrow 2CO_2(g) + 2H_2O(l)$$
$$\Delta H = -1.40 \times 10^3 \text{ kJ}$$

Calculate the amount of heat liberated when 4.79 g C_2H_4 reacts with excess oxygen.

83. Calculate the enthalpy change (ΔH) for the formation of nitrogen monoxide from its elements.

$$N_2(g) + O_2(g) \longrightarrow 2NO(g)$$

Use the following thermochemical equations:

$$4NH_3(g) + 3O_2(g) \longrightarrow 2N_2(g) + 6H_2O(l)$$
$$\Delta H = -1.53 \times 10^3 \text{ kJ}$$
$$4NH_3(g) + 5O_2(g) \longrightarrow 4NO(g) + 6H_2O(l)$$
$$\Delta H = -1.17 \times 10^3 \text{ kJ}$$

84. How much heat must be removed from a 45.0-g sample of liquid naphthalene ($C_{10}H_8$) at its freezing point to bring about solidification? The heat of fusion of naphthalene is 19.1 kJ/mol.

*85. If 3.20 kcal of heat is added to 1.00 kg of ice at 0°C, how much liquid water at 0°C is produced, and how much ice remains?

Think Critically

86. **Relate Cause and Effect** Your fingers quickly begin to feel cold when you touch an ice cube. What important thermochemical principle does this change illustrate?

87. **Calculate** You place a bottle containing 2.0 L of mineral water at 25°C into a refrigerator to cool to 7°C.
a. How many kJ of heat are lost by the water?
b. How many kJ of heat are absorbed by the refrigerator?
c. What assumptions did you make in your calculations?

88. **Evaluate** Consider the statement, "the more negative the value of $\Delta H_f°$, the more stable the compound." Is this statement true or false? Explain.

*89. **Calculate** When 1.000 mol of $N_2(g)$ reacts completely with 3.000 mol of $H_2(g)$, 2.000 mol of $NH_3(g)$ and 92.38 kJ of heat are produced.

$$N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g) + 92.38 \text{ kJ}$$

Use this thermochemical equation to calculate ΔH for the following reactions:
a. $2N_2(g) + 6H_2(g) \longrightarrow 4NH_3(g)$
b. $\frac{3}{2}N_2(g) + \frac{9}{2}H_2(g) \longrightarrow 3NH_3(g)$
c. $\frac{1}{2}N_2(g) + \frac{3}{2}H_2(g) \longrightarrow NH_3(g)$

90. **Explain** Why is fusion an endothermic process, but freezing is an exothermic process?

*91. **Calculate** An ice cube with a mass of 40.0 g melts in water originally at 25.0°C.
a. How much heat does the ice cube absorb from the water when it melts? Report your answer in calories, kilocalories, and joules.
b. Calculate the number of grams of water that can be cooled to 0°C by the melting ice cube.

92. **Evaluate and Revise** Evaluate this statement: "The energy content of a substance is higher in the liquid phase than in the vapor phase at the same temperature." If the statement is incorrect, restate it so it is correct.

93. **Apply Concepts** Using the following equations,

$$Ca(s) + 2C(s) \longrightarrow CaC_2(s)$$
$$\Delta H = -62.8 \text{ kJ}$$
$$CO_2(g) \longrightarrow C(s) + O_2(g)$$
$$\Delta H = 393.5 \text{ kJ}$$
$$CaCO_3(s) + CO_2(g) \longrightarrow CaC_2(s) + \frac{5}{2}O_2(g)$$
$$\Delta H = 1538 \text{ kJ}$$

determine the heat of reaction (in kJ) for

$$Ca(s) + C(s) + \frac{3}{2}O_2(g) \longrightarrow CaCO_3(s)$$

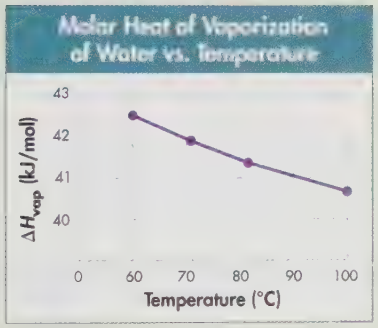
*94. **Calculate** The sugar glucose ($C_6H_{12}O_6$) is an important nutrient for living organisms to meet their energy needs. The standard heat of formation ($\Delta H_f°$) of glucose is −1260 kJ/mol. Calculate how much heat (in kJ/mol) is released at standard conditions if 1 mol of glucose undergoes the following reaction:

$$C_6H_{12}O_6(s) + 6O_2(g) \longrightarrow 6CO_2(g) + 6H_2O(l)$$

Enrichment

95. **Calculate** Ethane, $C_2H_6(g)$, can be formed by the reaction of ethene, $C_2H_4(g)$, with hydrogen gas.

$$C_2H_4(g) + H_2(g) \longrightarrow C_2H_6(g)$$



Use the heats of combustion for the following reactions to calculate the heat change for the formation of ethane from ethene and hydrogen.

$$2H_2(g) + O_2(g) \longrightarrow 2H_2O(l)$$
$$\Delta H = -5.72 \times 10^2 \text{ kJ}$$
$$C_2H_4(g) + 3O_2(g) \longrightarrow 2CO_2(g) + 2H_2O(l)$$
$$\Delta H = -1.401 \times 10^3 \text{ kJ}$$
$$2C_2H_6(g) + 7O_2(g) \longrightarrow 4CO_2(g) + 6H_2O(l)$$
$$\Delta H = -3.100 \times 10^3 \text{ kJ}$$

96. **Infer** An ice cube at 0°C was dropped into 30.0 g of water in a cup at 45.0°C. At the instant that all of the ice was melted, the temperature of the water in the cup was 19.5°C. What was the mass of the ice cube?

***97.** **Calculate** A 41.0-g piece of glass at 95°C is placed in 175 g of water at 21°C in an insulated container. They are allowed to come to the same temperature. What is the final temperature of the glass-water mixture? The specific heat of glass is 2.1 cal/(g·°C).

98. **Interpret Graphs** The molar heat of vaporization of water at various temperatures is given in the graph. Estimate the amount of heat required to convert 1 L of water to steam on the summit of Mount Everest (8850 m), where the boiling temperature of water is 70°C.

Write About Science

99. **Explain** Use the concept of heat capacity to explain why on a sunny day, the concrete deck around an outdoor swimming pool becomes hot, while the water stays cool.

100. **Compare** Why is a burn from steam potentially far more serious than a burn from very hot water?

CHEMYSTERY

Fighting Frost

If the temperature of the branches, leaves, and fruit of a citrus tree falls below 0°C, severe damage can occur. When ice crystals form in the plant cells, water becomes unavailable to the plant tissues. This lack of fluids can kill a young tree. The fruit itself can also be damaged by frost. The juice vesicles inside the fruit rupture as ice crystals form within them. These ruptured vesicles cause the fruit to lose water and dry out. Upon an impending frost, if the fruit is not ready for harvest, citrus growers must find a way to protect their precious crops.

Spraying the trees with water throughout the duration of a frost is an effective way to prevent the trees and fruit from freezing. The water freezes directly on the branches, leaves, and fruit. Freezing is an exothermic process. As the water freezes, it releases heat and prevents the plant cells from reaching freezing temperatures.

101. **Apply Concepts** Identify the system and the surroundings when water freezes on a citrus fruit.

***102.** **Predict** Evaporation of the water on a plant surface can occur under dry and windy conditions. How would this affect the citrus tree and fruit?

103. **Connect to the BIG IDEA** Explain, in terms of the law of conservation of energy, why the freezing of water on a citrus tree can cause the temperature of the tree to increase.

Answers

ENRICHMENT

95. -1.37×10^2 kJ

96. 9.6 g

97. 45.6°C

98. ΔH_{vap} for water at 70°C is approximately 42 kJ/mol. 1 L of water (1000 mL) has a mass of 1000 g and contains 55.6 mol water. Therefore, the amount of heat required is 42 kJ/mol × 55.6 mol = 2.34 10^3 kJ

WRITE ABOUT SCIENCE

99. Concrete has a lower specific heat capacity than water. As a result, it takes more heat to increase a certain amount of water of by 1°C than it does to increase the same amount of concrete by 1°C. Assuming that the water and concrete absorb the same amount of radiant energy from the sun, the temperature of the concrete will rise faster.

100. Steam at 100°C contains more energy than liquid water at 100°C. If steam touches your skin, it will condense releasing the heat of condensation.

CHEMYSTERY **APPLY CONCEPTS** After students have read through the CHEMystery, call on volunteers to summarize why spraying trees and fruit with water and letting it freeze is an effective way to protect the plants during freezing temperatures. **Ask** In terms of heat flow, what would most likely happen if the growers did *not* spray the plants with water during freezing temperatures? *(Heat would flow from the plant directly to the surrounding air, and water in the plant cells would freeze. Because freezing water expands, this process causes cell membranes and walls to rupture, leading to cell death.)* **Ask** Why must water be continually sprayed on the plants while the air temperatures are freezing? *(Although the ice provides a buffer that slows the loss of heat from the plant to the colder air, it is the freezing process that protects the plant by losing heat to the environment.)*

Point out that while most fruit trees tend to survive frost and freeze events, the freezing weather results in economic losses due to the destruction of existing fruit and flower buds. Annual and perennial vegetable and fruit plants are more severely affected by freezing because they do not have woody stems and have more delicate leaves. As a result, producers lose the plants along with the produce.

CHEMYSTERY ANSWERS

101. The system is the branches, leaves, and fruit. The surroundings are the water.

102. Evaporation is an endothermic process. As the water evaporates, it absorbs heat from the trees and fruit, causing their temperature to decrease. This can lead to the branches, leaves and fruit freezing.

103. **BIG IDEA** As the water freezes, it releases a certain amount of energy. In accordance with the law of conservation of energy, the tree gains the same amount of energy. The temperature of the tree increases as a result. No energy is created or destroyed during this process.

Cumulative Review

104. The manipulated variable is the variable you change during an experiment. The responding variable is the variable you observe during an experiment.

105. **a.** Cr **b.** Cu **c.** C **d.** Ca **e.** Cs

106. **a.** 6.99 m **b.** 10.68 g **c.** 3.6 × 102 m/s **d.** 4.44 °C

107.

Particle	Charge	Relative Mass	Location
proton	1+	1	nucleus
neutron	0	1	nucleus
electron	1–	1/1840	outside nucleus

108. 3.22 m

109. phosphorus, arsenic, germanium

110. **a.** 2
b. 2
c. 3
d. 1

111. A covalent bond is nonpolar when the electrons of the bonding atoms are shared equally. A covalent bond is polar when the electrons of the bonding atoms are shared unequally. The bond between oxygen atoms in the oxygen molecule (O_2) is nonpolar. The bond between a carbon atom and an oxygen atom in the carbon monoxide molecule is polar.

112. **a.** K_3N **b.** Al_2S_3 **c.** $Ca(NO_3)_2$ **d.** $CaSO_4$

113. 1.20×10^{24} H_2 molecules

114. $Ag(aq)^+ + Cl^-(aq) \rightarrow AgCl(s)$

115. $N_2(g) + O_2(g) \rightarrow 2NO_2(g)$
$2NO(g) + O_2(g) \rightarrow 2NO_2(g)$

116. 11.8 g O_2

117. 0.40

118. 11.1 L

119. Water is a very good solvent and dissolves at least a small part of most of what it comes in contact with in nature.

120. solutions; suspensions

Cumulative Review

104. Explain the difference between an independent variable and a dependent variable.

105. Write the correct chemical symbol for each element.
a. chromium
b. copper
c. carbon
d. calcium
e. cesium

***106.** Express the results of the following calculations with the correct number of significant figures.
a. 6.723 m × 1.04 m
b. 8.934 g + 0.2005 g + 1.55 g
c. 864 m ÷ 2.4 s
d. 9.258°C − 4.82°C

107. List three kinds of subatomic particles in an atom. Describe each kind in terms of charge, relative mass, and location with respect to the nucleus.

***108.** Calculate the wavelength of a radio wave with a frequency of $93.1 \times 10^6\ s^{-1}$.

109. List the following atoms in order of increasing atomic radius: phosphorus, germanium, arsenic.

110. How many chloride ions would be required to react with these cations to make an electrically neutral particle?
a. strontium cation
b. calcium cation
c. aluminum cation
d. lithium cation

111. How does a polar covalent bond differ from a nonpolar covalent bond? Which type of bond is found in molecular oxygen (O_2)? In carbon monoxide (CO)?

***112.** Write formulas for the following compounds:
a. potassium nitride
b. aluminum sulfide
c. calcium nitrate
d. calcium sulfate

***113.** How many hydrogen molecules are in 44.8 L $H_2(g)$ at STP?

114. Write the net ionic equation for the reaction of aqueous solutions of sodium chloride and silver acetate.

***115.** When lightning flashes, nitrogen and oxygen combine to form nitrogen monoxide. The nitrogen monoxide reacts with oxygen to form nitrogen dioxide. Write equations for these two reactions.

116. How many grams of oxygen are formed by the decomposition of 25.0 g of hydrogen peroxide?

$$2H_2O_2(l) \longrightarrow 2H_2O(l) + O_2(g)$$

117. What fraction of the average kinetic energy of hydrogen gas at 100 K does hydrogen gas have at 40 K?

***118.** A gas has a volume of 8.57 L at 273 K. What will be the volume at 355 K if its pressure does not change?

119. What property of water makes it impossible to find pure water in nature?

120. Do colloids, suspensions, or solutions contain the smallest particles? Which contain the largest particles?

Tips for Success

Eliminate Wrong Answers If you don't know which response is correct, start by eliminating those you know are wrong. If you can rule out some choices, you'll have fewer left to consider and you'll increase your chances of choosing the correct answer.

1. The ΔH_{fus} of ethanol (C_2H_6O) is 4.93 kJ/mol. How many kilojoules are required to melt 24.5 g of ethanol at its freezing point?
   (A) 2.63 kJ **(C)** 9.27 kJ
   (B) 4.97 kJ **(D)** 263 kJ
2. How much heat, in kilojoules, must be added to 178 g of liquid water to increase the temperature of the water by 5.0°C ?
   (A) 890 kJ **(C)** 3.7 kJ
   (B) 36 kJ **(D)** 0.093 kJ
3. The standard heat of formation of a free element in its standard state is always
   (A) zero.
   (B) positive.
   (C) negative.
   (D) higher for solids than for gases.
4. If ΔH for the reaction $2HgO(s) \longrightarrow 2Hg(l) + O_2(g)$ is 181.66 kJ, then ΔH for the reaction $Hg(l) + \frac{1}{2}O_2(g) \longrightarrow HgO(s)$ is
   (A) 90.83 kJ. **(C)** −90.83 kJ.
   (B) 181.66 kJ. **(D)** −181.66 kJ.
5. The specific heat capacity of ethanol is ten times larger than the specific heat capacity of silver. A hot bar of silver with a mass of 55 g is dropped into an equal mass of cool alcohol. If the temperature of the silver bar drops 45°C, the temperature of the alcohol
   (A) increases 45°C.
   (B) decreases 4.5°C.
   (C) increases 4.5°C.
   (D) decreases 45°C.
6. Hydrogen gas and fluorine gas react to form hydrogen fluoride, HF. Calculate the enthalpy change (in kJ) for the conversion of 15.0 g of $H_2(g)$ to HF(g) at constant pressure.

$$H_2(g) + F_2(g) \longrightarrow 2HF(g)$$
$$\Delta H = -536 \text{ kJ}$$

Use the graph and table to answer Questions 7–10. Assume 1.00 mol of each substance.

Substance	Freezing point (K)	ΔH_{fus} (kJ/mol)	Boiling point (K)	ΔH_{vap} (kJ/mol)
Ammonia	195.3	5.66	239.7	23.3
Benzene	278.7	9.87	353.3	30.8
Methanol	175.5	3.22	337.2	35.2
Neon	24.5	0.33	27.1	1.76

7. Calculate heat absorbed in region A for neon.
8. Calculate heat absorbed in region C for ammonia.
9. Calculate heat absorbed in regions B and C for methanol. [specific heat = 2.53 J/(g·°C)]
10. Calculate heat absorbed in regions A, B, and C for benzene. [specific heat = 1.74)/(g·°C)]

Materials List

For the Student

Quick Lab, p 600
- #0000 steel-wool pad
- tissue paper
- tongs
- Bunsen burner
- heat-resistant pad

Small-Scale Lab, p 635
- NaCl, NH_4Cl, $CaCl_2$
- thermometer
- 4 1-oz plastic cups
- plastic spoon
- crushed ice
- water
- stirring rod
- Optional solids: KCl, $NaHCO_3$, Na_3PO_4

For the Teacher

Teacher Demo, p 599
- 10 mL ethanoic acid
- 10 mL isoamyl alcohol
- 2 test tubes
- anhydrous calcium sulfate
- sulfuric acid, water

Teacher Demo, p 612
- 10 mL ethanoic acid
- 10 mL isoamyl alcohol
- 2 test tubes
- anhydrous calcium sulfate
- sulfuric acid • water

Teacher Demo, p 615
- 3 g copper turnings
- 3 heat-resistant test tubes
- 10 mL of 6M nitric acid
- one-hole stopper
- 2 solid stoppers
- glass delivery tube
- rubber tubing
- warm water bath
- ice water bath

Class Activity, p 623
- calculator
- paper
- pencil
- colored markers

Class Activity, p 625
- saturated solutions of AgCl and $AgNO_3$
- 2 test tubes
- dropper

Teacher Demo, p 631
- block of ice
- 2 beakers
- water • hot plate

Teacher Demo, p 633
- 0.1M solution of $KMnO_4$ in 0.1M HCl
- graduated cylinder
- 1000-mL beaker
- thermometer
- 20 mL of 30% H_2O_2
- watch glass
- splint • matches

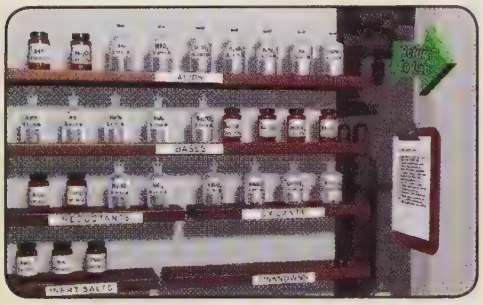
18.4 Virtual Chem Lab 20: Enthalpy and Entropy
Enthalpy and Entropy



What's Online

CHEM TUTOR Students access guided, step-by-step tutorials for solving various reaction rate and equilibrium problems.

PROBLEM SETS Students can practice key problem-solving skills in an online problem set.

MATH HELP Identify the students who struggle with math by assigning an online math skills diagnostic test. These students can then improve and practice math skills using the MathXL tutorial system.

VIRTUAL LAB Students go into a virtual lab tour in which enthalpy and entropy are studied in a simulated laboratory environment.

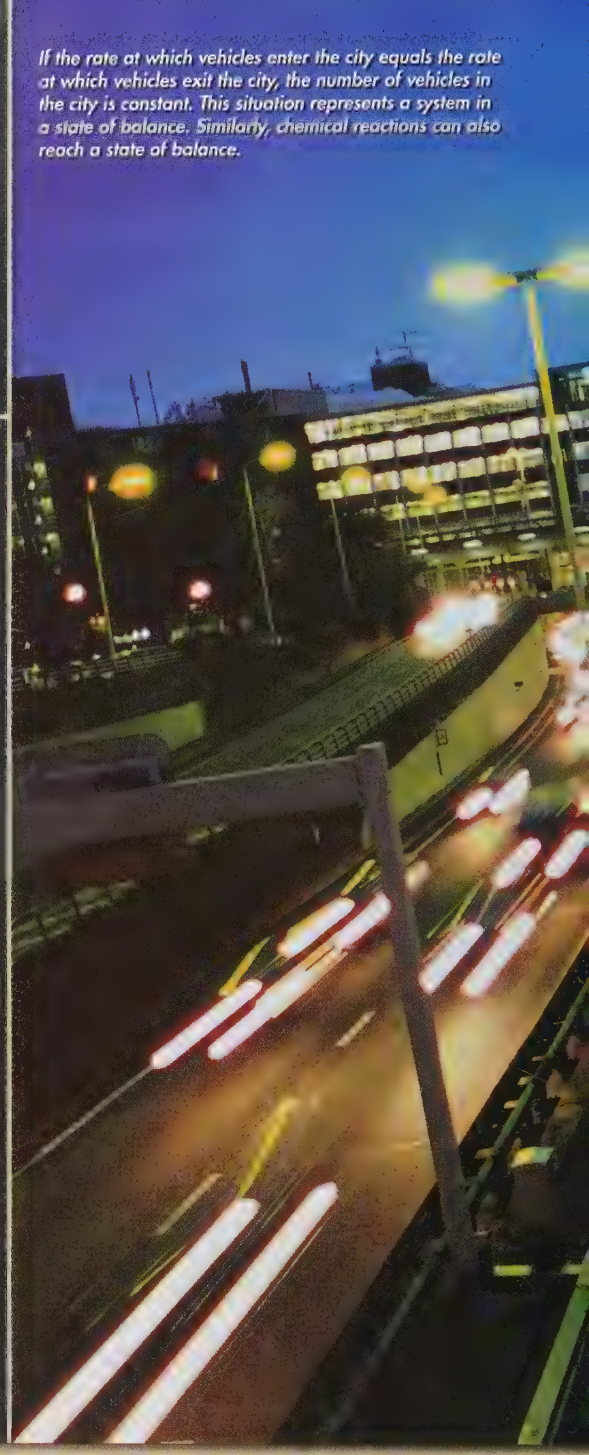
KINETIC ART Students watch animations of selected figures form the chapter and then answer questions that check for understanding.

CONCEPTS IN ACTION Students watch an overview of a key chapter concept using real-world contexts and concrete examples and analogies. Each activity includes an interactive animation followed by analysis questions.

IN ACADEMIC STANDARDS for SCIENCE

Nature of Science

- Develop explanations based on reproducible data and observations gathered during laboratory investigations.
- Clearly communicate their ideas and results of investigations verbally and in written form using tables, graphs, diagrams, and photographs.



Standard 7: Solutions

C.7.2 Explain how changes in temperature, surface area, and pressure affect solubility.

C.7.5 Explain how the rate of a reaction is qualitatively affected by changes in concentration, temperature, surface area, and the use of a catalyst.

C.7.6 Write equilibrium expressions for reversible reactions.

18 Reaction Rates and Equilibrium

If the rate at which vehicles enter the city equals the rate at which vehicles exit the city, the number of vehicles in the city is constant. This situation represents a system in a state of balance. Similarly, chemical reactions can also reach a state of balance.

INSIDE:

Focus on ELL

1 CONTENT AND LANGUAGE Write the title of the chapter and lesson titles on the board. Underline the word *equilibrium* in the appropriate titles. Explain that *equilibrium* is from the Latin *aequi-*, meaning "equal," and *libra,* meaning "balance." Have students use this information to predict what a chemical reaction at *equilibrium* means.

BEGINNING

LOW Use pictures or symbols to represent unfamiliar words from the titles. Rewrite the titles using these symbols in place of the words.

HIGH Use a bilingual dictionary or glossary to find any cognates to any unfamiliar words from the titles.

INTERMEDIATE: LOW/HIGH Write simplified English definitions of the titles and present them to the class.

ADVANCED: LOW/HIGH Write the definition of each word in each title and surmise to the class the purpose of the chapter and the main ideas of each lesson.

BIG IDEAS

- REACTIONS
- MATTER AND ENERGY

Essential Questions:

1. *How can the rate of a chemical reaction be controlled?*
2. *What is the role of energy in chemical reactions?*
3. *Why do some reactions occur naturally, and others do not?*

CHEMYSTERY

Explosive Sugar

At a sugar refinery, sugar is processed until it is pure enough to sell to consumers. Conveyor belts connect large storage silos to the packaging warehouse. In February 2008, workers at a refinery in Georgia heard a small explosion. The sound came from the location where the conveyor belts entered the warehouse.

Five minutes later, a much larger explosion occurred, which destroyed the warehouse. The fire spread to the storage silos. Thirteen workers died, and dozens more were injured. It took four days for 232 firefighters to put out the fire in the warehouse. The fire in the silos took a few days longer to extinguish.

How did the first small explosion lead to the second, more destructive explosion?

▶ Connect to the BIG IDEA As you read about reaction rates, think about what could cause an explosion at a sugar refinery.

INDIANA'S ACADEMIC STANDARDS FOR SCIENCE

Solutions C.7.2, C.7.5, C.7.6. See lessons for details.

Introduce the Chapter

IDENTIFY MISCONCEPTIONS Some students may not realize that some chemical reactions are reversible. Use the activity to introduce the concepts of reversible reactions and equilibrium.

ACTIVITY *You will need one or more light-sensitive or temperature-sensitive products, such as eyeglasses or toys.* Allow time for students to handle the products in different lighting or water baths of different temperatures to observe how the color changes in response to lighting conditions or temperature. Point out how the color gradually changes and adjusts to the level of light or temperature. **Ask** Why do you think the color changes? *(The ultraviolet light or heat causes a chemical change in the material.)* What causes the product to change back to its original color? *(A different chemical reaction occurs in the absence of heat or light.)* Point out that in these reactions, the degree of color change depends on a balance between the reaction that changes the color and the reverse reaction that changes the color back.

UbD

Understanding by Design

Students are building toward understanding how matter and energy behave in chemical reactions by applying the concepts of reaction rates and equilibrium.

PERFORMANCE GOALS At the end of Chapter 18, students will be able to answer the essential questions by applying their knowledge of reaction rates and equilibrium. Students will also be able to solve problems related to reactions using the equilibrium constant.

ESSENTIAL QUESTIONS Read the essential questions aloud. **Ask** How does raising the temperature of a substance affect particle movement? *(The particles move faster.)* Do you think this will increase or decrease the rate of a chemical reaction? *(It would most likely increase the rate.)* What is an everyday example of a chemical reaction that only occurs if you increase the energy of a substance? *(Sample answer: cooking eggs)* Tell students that in this chapter they will read about several factors, including energy, that affect the rates of chemical reactions.

BIG IDEA Use the photo of vehicles moving in and out of a city to help students connect to the concepts they will learn in this chapter. Activate prior knowledge by discussing traffic within a city. **Ask** Identify similar scenarios in which people or materials move into and out of an area. *(Sample answers: students moving into and out of a lunchroom and rain falling into a lake and evaporating.)* **Ask** In each situation, what would have to happen for the number of people or amount of materials in an area to remain unchanged? *(The number or amount moving in must equal the number or amount moving out.)* Tell students to keep this idea in mind as they work through the chapter.

CHEMYSTERY Have students read over the CHEMystery. Connect the CHEMystery to the Big Ideas by having students think about how the concentration of substances might relate to the explosions discussed in the CHEMystery. Point out that an explosion is the result of a combustion reaction, and explain that sugar dust is highly combustible. Remind students that combustion reactions are exothermic, and that the energy released from an exothermic reaction can take more than one form. For example, explosions generate a shock wave that causes objects far away from the reaction to vibrate. If these objects are covered in a layer of dust, the dust is released into the air. Have students predict how the release of a large cloud of sugar dust might make a second explosion more likely.

LESSON 18.1

Key Objectives

DESCRIBE how to express the rate of a chemical reaction.

IDENTIFY four factors that influence the rate of a chemical reaction.

Engage

CHEMISTRY & YOU Explain that all chemical reactions occur at rates specific to the nature of the reactants. **Ask** How can the rate of the corrosion of iron-magnesium alloy be increased? *(by adding salt water)* **Ask** What do you think can be added to the iron-magnesium alloy to increase the speed at which rusting occurs? *(add salt water)*

Build Background

Brainstorm reasons for the length of time it takes for a person to undergo a chemical hair treatment. **Ask** Do you know why there is a waiting period? *(It takes time for the chemical color or other treatment to affect the hair.)* **Ask** Why do you sometimes sit under a hair dryer? *(To speed up the process.)* Explain to the class that a hair coloring process involves a chemical reaction. The rate of the reaction depends on the initial characteristics of the client's hair as well as a variety of factors.

IN ACADEMIC STANDARDS for SCIENCE

- Develop explanations based on reproducible data and observations gathered during laboratory investigations.

C.7.5 Explain how the rate of a reaction is qualitatively affected by changes in concentration, temperature, surface area, and the use of a catalyst.

18.1 Rates of Reaction

C.7.5 Factors affecting rate of reaction

CHEMISTRY & YOU

Q: *How can rusting be used to cook a meal?* Sometimes a soldier or hiker wants a hot meal but has no place to cook it. Normally, rusting takes place at such a slow rate that the heat released could not be used to cook a meal. However, there are products that use the rusting of an iron-magnesium alloy to heat packaged food. These products are known as Meals Ready to Eat, or MREs for short.

Key Questions

How is the rate of a chemical reaction expressed?

What four factors influence the rate of a chemical reaction?

Vocabulary

- rate
- collision theory
- activation energy
- activated complex
- inhibitor

Describing Reaction Rates

How is the rate of a chemical reaction expressed?

When you strike a match, it erupts into flame almost instantly and burns quickly. Other reactions occur more slowly. For example, millions of years were required for plants buried beneath Earth's surface to be converted to coal. These examples show that the speed of chemical reactions can vary from very fast to extremely slow.

The concept of speed is a familiar one. In a race, speed determines the winner. The swimmers in Figure 18.1 are competing in a 100-meter race. (The pool is 25 meters long, so they must swim four lengths of the pool to finish the race.) A world-class swimmer might finish the race in 54.5 seconds. His average speed can be calculated by using the following equation:

$$\text{Average speed (m/s)} = \frac{\text{Distance (m)}}{\text{Time (s)}}$$

The swimmer's average speed, which is expressed in meters per second, is 100 m/54.5 s = 1.83 m/s. A slower swimmer might take 60.0 seconds to cover the same distance. He swims at an average speed of 1.67 m/s. Both 1.83 m/s and 1.67 m/s express rates of travel.

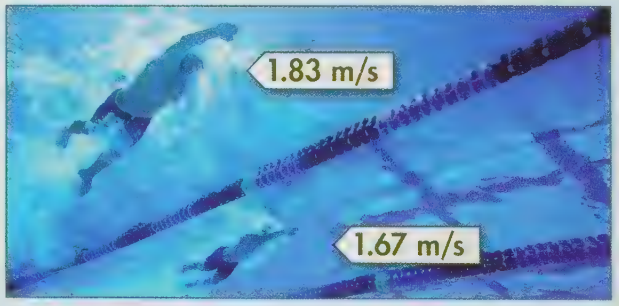

Figure 18.1 Speed
Speed is a change in distance over a given interval of time. A swimmer's average speed can be expressed in units of m/s.

Focus on ELL

1 CONTENT AND LANGUAGE Write the words *rate* and *speed* on the board. Explain that these words are sometimes used interchangeably in everyday conversation but do not have the same meaning in science. Direct students' attention to the paragraph that explains the term *rate*. Emphasize that in science, referring to the *speed* of a reaction would be inappropriate, because speed is a change in distance over time.

2 FRONTLOAD THE LESSON Preview the figures in the lesson. Point out the use of the words *rate, progress,* and *change* in the titles, labels, and captions to reinforce the concept that this lesson is about change over time. As a class, brainstorm a list of other familiar rates and write them on the board.

3 COMPREHENSIBLE INPUT When discussing collision theory, demonstrate the clay ball analogy described in the text.

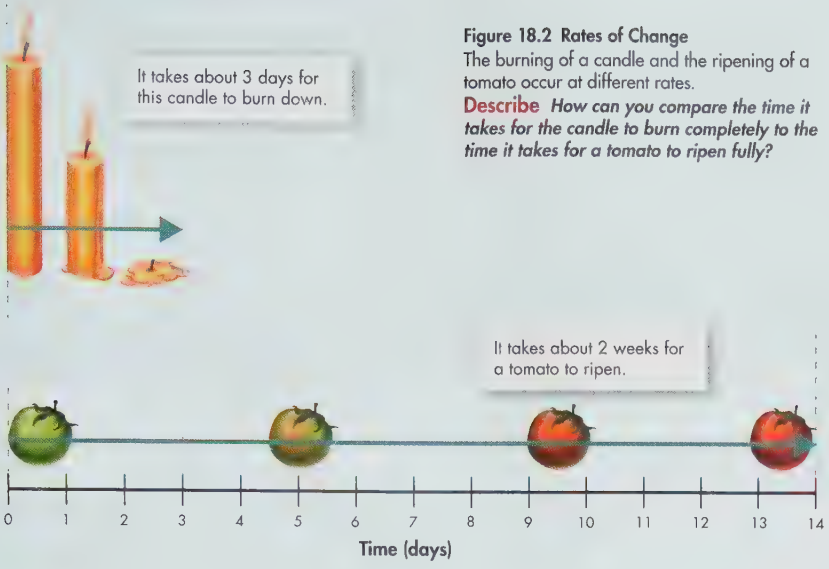

Figure 18.2 Rates of Change
The burning of a candle and the ripening of a tomato occur at different rates.
Describe ***How can you compare the time it takes for the candle to burn completely to the time it takes for a tomato to ripen fully?***

Rates of Change Speed is an example of a rate. A **rate** is a measure of how much something changes within a specified amount of time. The interval of time can range from less than a second to centuries. Figure 18.2 compares the rate of two changes—the burning of a candle and the ripening of a tomato.

In chemistry, the rate of a chemical reaction, or the reaction rate, is usually expressed as the change in the amount of reactant or product per unit time. The amount of a reactant is usually expressed in moles. For example, if one half of a 1-mole piece of iron turns to rust in one year, the rate at which iron rusts might be expressed as 0.5 mol/yr. This number is an average rate. Figure 18.3 illustrates the progress of a typical reaction. Over time, the amount of reactant decreases and the amount of product increases.

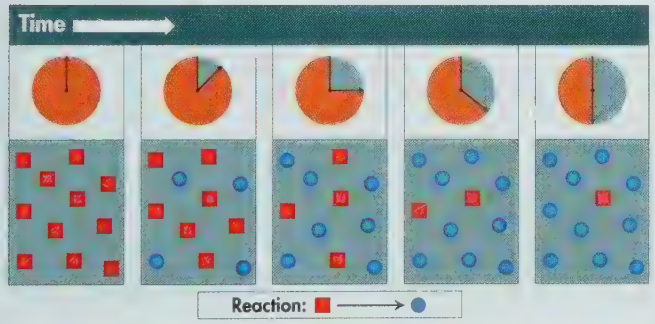

Figure 18.3 Reaction Progress
During a reaction, reactants are converted into products. The red squares represent the reactants. The blue circles represent the products. Assume that each box represents the same time interval.
Interpret Diagrams ***Is the rate of conversion of reactant to product constant throughout the reaction? How can you tell?***

UbD Check for Understanding

How is the rate of a chemical reaction expressed?

Assess students' understanding of the expression of reaction rate as a change in the amount of reactant per unit time by having students giving a thumbs-up sign if they understand the concept and a thumbs-down if they do not.

ADJUST INSTRUCTION If students indicate that they do not understand the concept, direct their attention to Figure 18.3. Demonstrate mathematically that if the time elapsed for the reaction is 0.5 minutes and each red square represents 1 mole reactant, then the reactant is decreasing at an average rate of 10 mol/0.5 minutes, or 0.33 mol/s.

Foundations for Reading

BUILD VOCABULARY Have students create a concept map around the term *collision theory*. They should complete the map with remaining vocabulary terms as they read the lesson.

READING STRATEGY Have students create a flow chart for each factor that affects reaction rates. The chart should show the factor, its direct effect, and its effect on the rate of reaction.

Explain

Describing Reaction Rates

START A CONVERSATION Point out that the time required for a chemical change to take place may be less than 10^{-6} seconds or more than 10^{6} years. Draw three vertical columns on the board and label the headers of each column "very fast," "average," and "very slow." Have the class brainstorm scenarios of chemical changes that fit into each category. If students are having trouble, guide students to think of common changes that occur within their own homes, for instance, how quickly bleach removes mold from a shower stall or how quickly it removes coloring from an article of clothing, or how quickly milk spoils if kept in the refrigerator versus being left outside on a warm day, or how long it takes for grass clippings to decompose in a compost pile.

USE VISUALS Direct students to study Figure 18.3. **Ask** As you move from the diagram on the far left to the diagram on the far right, how does the concentration of the reactant change? *(It decreases.)* Explain that the rates of chemical reactions are often measured by the decrease in the concentration of one of the reactants or the increase in the concentration of one of the products. **Ask:** What happens to the reaction rate as the concentration of reactants decreases? *(It slows down.)*

Answers

FIGURE 18.2 You can compare the two rates by dividing one rate by the other rate expressed in the same units: 14/3 = 4.7 (The tomato ripen about 4.7 times faster than the candle burns.) or 3/14 = 0.21 (The candle burns about 21 percent slower than the tomato ripens.)

FIGURE 18.3 No; The number of additional blue circles—the products—decreases in each successive time interval.

Explain

USE VISUALS Direct students to Figure 18.4. Point out that in both (a) and (b) the particles collide. But only in (a) do the particles actually stick together. Stress that for particles to react and form bonds, three events must occur:

1. The particles must collide.
2. The particles must collide at the proper orientation.
3. The particles must have enough kinetic energy to cross the activation energy barrier.

Misconception Alert

Students may have difficulty accepting collision theory because they tend to visualize atoms and molecules wedged together with no spaces in between them, as shown in space-filling models. Remind students that in Chapter 13 they learned that, according to kinetic theory, all matter is made of tiny particles that are in constant motion, and that between the particles there is empty space.

USE AN ANALOGY Relate the activation energy barrier to a hill covered in snow. Tell the students to imagine they are rolling a large snowball up the hill. Once they get to the top of the hill, they will push the snowball over the hill. Explain that when they first begin to move the snowball, very few students are needed to move it because they are moving over flat ground, but as they begin moving up the hill, more students must join in to continue moving the snowball forward. **Ask** What would happen if enough people are not available to push the snowball all the way to the top of the hill? *(The snowball would not go over the hill.)* **Ask** How is the least number of students needed to push the snowball over the top of the hill analogous to the activation energy of a reaction? *(The activation energy is the minimum amount of energy needed for the reactants to form an activation complex.)*

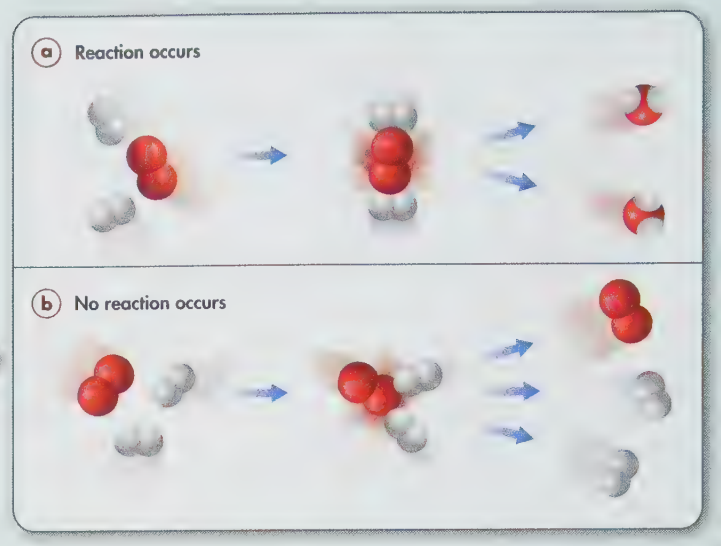

Figure 18.4 Collision Theory If colliding particles have enough kinetic energy and collide at the right orientation, they can react to form a new product. **a.** An effective collision of oxygen and hydrogen molecules produces water molecules. **b.** An ineffective collision of oxygen and hydrogen molecules produces no reaction; the reactants bounce apart unchanged.

Go online to see collision theory animated.

Collision Theory A model called collision theory is used to relate the properties of particles to the rates of reactions. According to **collision theory,** atoms, ions, and molecules can react to form products when they collide if the particles have enough kinetic energy. Particles that do not have enough energy to react bounce apart unchanged when they collide. Figure 18.4 shows what can happen when hydrogen and oxygen molecules collide.

You can use two balls of soft modeling clay to illustrate collision theory. If you throw the balls of clay together gently, they don't stick to one another. This situation is analogous to colliding particles of low energy that fail to react. If the same balls of clay are thrown together with great force, they will stick tightly to each other. This situation is analogous to the collision of two high-energy particles that results in the formation of a product.

You can also use modeling clay to illustrate another point about chemical reactions. Roll the clay into a rope and begin to shake one end more and more vigorously. At some point, the clay rope will break. Similarly, if enough energy is applied to a molecule, the bonds holding the molecule together can break, forming different products.

The minimum energy that colliding particles must have in order to react is called the **activation energy.** You can think of the activation energy for a reaction as a barrier that reactants must cross before products can form. Look at the diagrams in Figure 18.5. When two reactant particles collide, they may form an activated complex. An **activated complex** is an unstable arrangement of atoms that forms for a moment at the peak of the activation-energy barrier. The activated complex forms only if the colliding particles have enough energy and if the atoms are oriented properly. The lifetime of an activated complex is typically about 10^{-13} seconds. Its brief existence ends with the reformation of the reactants or with the formation of products. The two outcomes are equally likely. Thus, the activated complex is sometimes called the *transition state.*

Differentiated Instruction

ELL ENGLISH LANGUAGE LEARNERS Verify students' understanding of the terminology in the questions in Figure 18.5 by having students restate the questions in their own words.

L1 SPECIAL NEEDS Create a model of colliding molecules with fuzzy, lightweight balls and a hook and loop backboard. Tell students that if they throw the balls hard enough, the "molecules" will stick to the backboard or *react*. If they miss or throw with too little kinetic energy, the molecules will not *react*.

L3 ADVANCED STUDENTS Tell students that collision theory uses two-particle collisions to explain reaction mechanisms because the probability of three or more particles colliding simultaneously is unlikely. Have students research typical reactions that require the collision of three or more particles and summarize their findings in a report that they present to the class.

Collision theory explains why some reactions are extremely slow at room temperature. For example, carbon and oxygen react when charcoal burns, but the reaction has a high activation energy. The O—O bonds and C—C bonds must be broken to form the activated complex. At room temperature, the collisions of oxygen and carbon molecules are not energetic enough to break the bonds. Thus, the reaction rate of carbon with oxygen at room temperature is essentially zero.

InterpretGraphs

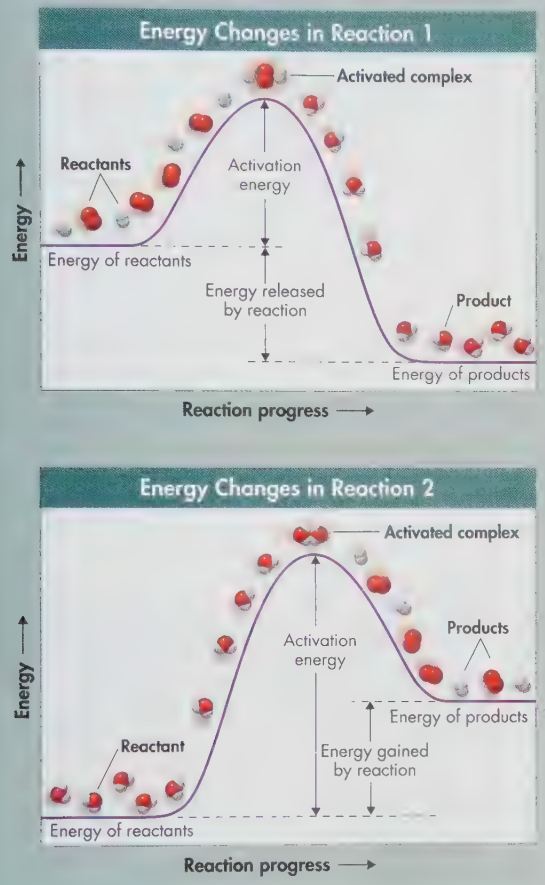

Figure 18.5 The activation-energy barrier must be crossed before reactants are converted to products.

a. Read Graphs Is energy absorbed or released as a reaction progresses from the reactants to the activated complex?

b. Compare How are the graphs for reactions 1 and 2 different?

c. Classify Which reaction is endothermic and which is exothermic? How do you know?

d. Explain Why might a reaction that releases energy require some energy before the reaction will begin?

e. Draw Conclusions Once an activated complex forms, does it always proceed to form products?

Remember: An endothermic reaction absorbs heat, and an exothermic reaction releases heat.

UbD Check for Understanding

BIGIDEA MATTER AND ENERGY Have each student write a one-minute summary explaining the role of activation energy in a chemical reaction. Tell students they can include a graph or an analogy to help them convey the information.

ADJUST INSTRUCTION If students are having difficulty with this concept, guide them in a step-by-step review of Figure 18.5.

USE VISUALS Direct students' attention to Figure 18.5. Point out that the diagram graphically depicts the energy changes that occur during a chemical reaction. Explain that the activation-energy hill must be crossed before reactants can be converted to products. **Ask** How does a large activation energy affect reaction time? *(It causes reaction time to increase, slowing the reaction.)* Explain that when the activation energy is great, fewer molecules are colliding with enough energy to form an activated complex at any one time, so it takes longer for the reaction to proceed to completion.

CRITICAL THINKING Have students consider whether changing the temperature of the reactants will affect the size of the activation energy barrier. *(No; an increase in temperature will only increase the number of reactants having the activation energy needed to react.)* Tell students that they will explore this concept in more detail shortly.

Answers

INTERPRET GRAPHS

a. absorbed

b. The graph for reaction 2 is the opposite of the graph for reaction 1.

c. Reaction 1 is exothermic because energy (in the form of heat) is released. Reaction 2 is endothermic because energy (in the form of heat) is gained.

d. An activated complex, which has a higher energy, needs to be formed before the reaction will proceed.

e. No; it could also revert to the reactants.

Explain

Factors Affecting Reaction Rates

CRITICAL THINKING Point out that an increase in temperature causes an increase in average kinetic energy. Explain that the number of collisions increases because the molecules are moving faster. More important, a greater number of the collisions are effective. **Ask** How do refrigerators prevent food from spoiling? *(The kinetic energy of reactants is reduced, so fewer particles possess sufficient energy to react. As a result, reactions that lead to spoilage take longer to occur.)*

Extend

Connect to FOOD CHEMISTRY

One of the key reasons that food spoils, other than microbial activity, is that many foods contain compounds that are highly reactive with oxygen. When these compounds react with oxygen, they oxidize. This oxidation causes the food to become rancid and turn brown. Even though refrigeration slows these reactions, food chemists also rely on a class of compounds called *antioxidants* to further slow food spoilage. Some fresh foods are natural sources of antioxidants, which gives them a slightly longer shelf life than those which are low in these compounds. Many processed foods have these substances added during the manufacturing process.

Have students research antioxidants and create posters that explain what antioxidants are, how they work, and that identify natural and processed foods that contain antioxidants.

Factors Affecting Reaction Rates

What four factors influence the rate of a chemical reaction?

Every chemical reaction proceeds at its own rate. Some reactions are naturally fast, and some are naturally slow under the same conditions. However, by varying the conditions, you can modify the rate of almost any reaction.

Factors that can affect the rate of a chemical reaction are temperature, concentration, particle size, and the use of a catalyst. Collision theory helps explain why changing one or more of these factors may affect the rate of a chemical reaction.

Temperature Usually, raising the temperature speeds up a reaction. Lowering the temperature usually slows down a reaction. At higher temperatures, particles move faster. The frequency of collisions increases along with the percentage of particles that have enough kinetic energy to slip over the activation-energy barrier. Thus, an increase in temperature causes products to form faster.

A familiar example of the effect of temperature on reaction rate is the burning of charcoal. The reactants are carbon and oxygen. The product is carbon dioxide. At room temperature, a bag of charcoal in contact with air does not burn. However, when a starter flame touches the charcoal, carbon atoms and oxygen molecules collide with higher energy and greater frequency. Some collisions are at a high enough energy to form the product. The heat released by the reaction then supplies enough energy to get more carbon and oxygen over the activation-energy barrier. When the starter flame is removed, the reaction continues.

Concentration In a crowded room where people are moving about, you may find yourself bumping into people more frequently than if there were only a few people in the room. Similarly, the number of particles in a given volume affects the rate at which reactions occur. Cramming more particles into a fixed volume increases the concentration of reactants and, thus, the frequency of collision. Increased collision frequency leads to a higher reaction rate.

The lighted splint in Figure 18.6 glows in air and soon dies out because air is only 20 percent oxygen. But when the glowing splint is plunged into pure oxygen, it immediately bursts into flame. The increased concentration of oxygen greatly speeds up the combustion reaction.

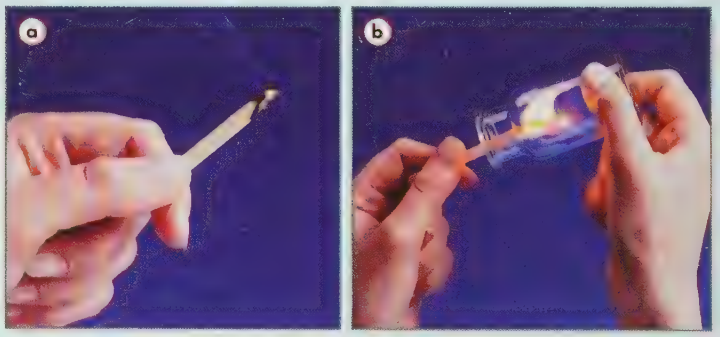

Figure 18.6
Effect of Concentration on Reaction Rate
The rate of a reaction depends upon the concentrations of the reactants. **a.** In air, a lighted splint glows and soon goes out. **b.** When placed in a vial containing pure oxygen, the splint bursts into flame.
Infer ***In areas where oxygen tanks are used, why do warning signs say "No smoking. No open flames"?***

Professional Development Note

Northern Lights

The term *northern lights* is commonly used to refer to the aurora borealis, an astronomical spectacle that happens as a result of electrically charged particles reacting with gases in the upper atmosphere. The particles that help to produce this colorful display of light originate from the massive nuclear reactions that occur in the sun. Highly energized fragments of atoms released from these reactions travel at extreme rates of speed and bombard the upper atmosphere, causing some of the nitrogen molecules to dissociate. When two excited nitrogen atoms recombine and produce the fluorescence of molecular nitrogen, the green, blue, or purple lights of the aurora borealis are the result. Scientists have tried with no success to recreate theses colored lights in the laboratory. So far, there is no amount of thermal energy available under laboratory conditions equal to the energy of the bombarding charged particles released by the sun.

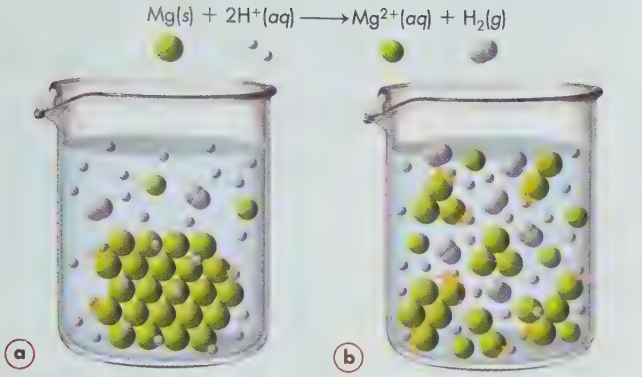

Figure 18.7 Effect of Particle Size on Reaction Rate
When a piece of magnesium is placed in a dilute acid, hydrogen ions can collide with magnesium atoms.
a. Only atoms at the surface of the metal are available for reaction.
b. Dividing the metal into smaller pieces increases the surface area and the number of particle collisions.
Explain *How does increasing the number of collisions increase the reaction rate?*

Particle Size If you put a bundle of sticks on a fire, they burn quickly. A log with the same mass burns more slowly. The small pieces of wood have more surface area than the log, and surface area plays an important role in determining the rate of the combustion reaction. The same is true for other chemical reactions because collisions occur at the surface of particles.

The total surface area of a solid or liquid reactant affects the rate of a reaction. The smaller the particle size, the greater the surface area is for a given mass of particles. Figure 18.7 shows how a decrease in particle size affects the amount of a reactant exposed for reaction. When a piece of metal is divided into several smaller pieces, the total surface area increases. The result of an increase in surface area is an increase in the frequency of collisions and the reaction rate.

Another way to increase the surface area of solids is to dissolve them. In a solution, particles are separated and more accessible to other reactants. You can also increase the surface area of a solid by grinding it into a fine powder. Small dustlike particles, however, can be dangerous when suspended in air. As coal miners know, coal dust mixed with air is an explosive hazard because of the large surface area of the coal dust particles. The same risk exists in flour mills, grain elevators, and sugar refineries. The photograph in Figure 18.8 shows a sugar refinery in Georgia after such an explosion.

Figure 18.8 Dust Explosion
An explosion destroyed this sugar refinery. The tiny size of the reactant particles (sugar dust) caused the reaction of sugar with oxygen in the air to be explosive.

Explore

Teacher Demo

PURPOSE Students observe the effect of heat and a catalyst on the rate of a chemical reaction.

MATERIALS 10 mL ethanoic acid, 10 mL isoamyl alcohol, 2 test tubes, anhydrous calcium sulfate, concentrated sulfuric acid, water

PROCEDURE Mix 5 mL ethanoic acid *(acetic acid)* and 5 mL isoamyl alcohol in each of two test tubes. Add a few granules of anhydrous calcium sulfate to each test tube. To one test tube, add three drops of concentrated sulfuric acid and heat this test tube in a boiling water bath for a few minutes. Write the general chemical equation for the formation of an ester on the board.

(organic acid + alcohol → ester + water)

Inform students that esters are responsible for the characteristic odors of many fruits and may be prepared by reacting an organic acid with an alcohol. Have students smell the odor emanating from both test tubes by carefully wafting the odor towards their noses. **Ask** What do you observe? *(The heated solution containing sulfuric acid smells like bananas while the other solution has a strong odor of vinegar (ethanoic acid).)* Tell students that a change in odor is a sign of a reaction. **Ask** What purpose does the boiling water bath serve in this reaction? *(It increases the temperature of one of the reactants, which speeds up the reaction rate.)* **Ask** What is the purpose of the sulfuric acid in this reaction? *(The sulfuric acid is a catalyst for the reaction; it speeds up the rate of reaction.)*

EXPECTED OUTCOME

The solution containing sulfuric acid smells like bananas after being heated, whereas the other solution smells like vinegar, or ethanoic acid.

Professional Development Note

Kinetics

In 1903, Svante Arrhenius, a Swedish chemist associated with two concepts present in most kinetic theories, *activation energy* and the *Arrhenius equation*, became the first Swede to be awarded the Nobel Prize in chemistry. The Arrhenius equation,

$$E_a = -RT \ln\left(\frac{k}{A}\right)$$

quantifies the relationship between the temperature dependence on the rate constant k and the activation energy E_a for any given chemical reaction. Arrhenius suggested that when a reaction occurs at an absolute temperature T, a proportional relationship exists between the fraction of molecules that have a kinetic energy greater than E_a and the probability distribution of molecular speed, otherwise known as the Maxwell-Boltzmann distribution of statistical mechanics.

Answers

FIGURE 18.6 The concentration of the reactant, oxygen, is increased.

FIGURE 18.7 More frequent collisions mean more frequent reactions between colliding particles. The percentage of particles that have enough energy to react remain constant, but the number of successful collisions in a given time interval is greater.

LESSON 18.1

Explore

QuickLab

OBJECTIVE After completing this activity, students will be able to relate particle size or surface area to the rate of a reaction and write a balanced equation for the reaction.

SKILLS FOCUS observing, writing equations, inferring

PREP TIME 20 minutes

CLASS TIME 20 minutes

SAFETY Steel wool burns readily. Use proper safety precautions.

EXPECTED OUTCOME

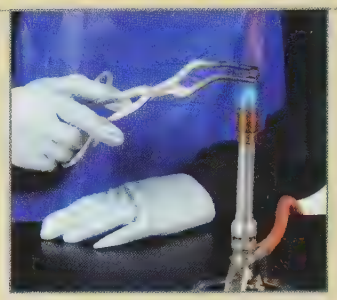
Tight ball: except for the glowing of a few loose steel fibers on the surface, there are no apparent changes; loose ball: glows; loose fibers: burn readily.

ANALYZE AND CONCLUDE

1. Except for the glowing of a few loose steel fibers on the surface, no apparent changes occurred when the tight ball was heated. The loose ball glowed. The loose fibers burst into flame almost immediately.
2. The ball acts like a single large particle of steel that is in contact with atmospheric oxygen only at its relatively small surface. The loose fibers act like many small particles, with larger total surface area, and each small particle is exposed to atmospheric oxygen.
3. $4Fe(s) + 3O_2(g) \rightarrow 2Fe_2O_3(s)$
4. The combustion of the steel wool is faster because the high temperature provides the energy for the iron and oxygen to overcome the activation-energy barrier. The small particle size exposes more of the iron surface to atmospheric oxygen.
5. The steel wool may ignite.

QuickLab

Does Steel Burn?



Purpose To determine whether steel will burn

Materials

- #0000 steel wool pad
- tongs
- gas burner
- heat-resistant pad
- tweezers

Procedure

1. Roll a small piece of steel wool into a very tight, pea-sized ball.
2. Holding the ball with tongs, heat the steel wool in the blue-tip flame of the burner for no longer than 10 seconds. **CAUTION** *Observe all precautions for working with flames.*
3. Place the heated steel wool on the heat-resistant pad to cool. Record your observations.
4. Gently roll a second small piece of steel wool into a loose ball. Repeat Steps 2 and 3.

5. Use tweezers to pull a few individual fibers of steel wool from the pad. Hold one end of the loose fibers with the tongs. Repeat Steps 2 and 3.

Analyze and Conclude

1. **Observe** What differences did you observe when the tight ball, the loose ball, and the loose fibers were heated in the flame?
2. **Relate Cause and Effect** Give a reason for any differences you observed.
3. **Describe** Write the balanced equation for any chemical reaction you may have observed. Assume that the steel wool is composed mainly of iron.
4. **Compare and Contrast** How do your results differ from those observed in the rusting of an automobile body?
5. **Apply Concepts** Explain why steel wool is a hazard in shops where there are hot plates, open flames, or sparking motors.

CHEMISTRY & YOU

***Q:** When salt water is added to the metal alloy in an MRE, the rate of the rusting reaction increases, and heat is produced rapidly. Which factor that can affect reaction rates is being applied in this situation?*

Catalysts Increasing the temperature is not always the best way to increase the rate of a reaction. A catalyst is often better. Recall that a catalyst is a substance that increases the rate of a reaction without being used up during the reaction. Catalysts permit reactions to proceed along a lower energy path. Figure 18.9 shows that the activation-energy barrier for the catalyzed reaction is lower than that of the uncatalyzed reaction. When the barrier is lower, a greater fraction of reactants have the energy to form products within a given time. For instance, the rate of the reaction of hydrogen and oxygen at room temperature is negligible. But with a small amount of platinum (Pt) as a catalyst, the reaction is rapid.

$$2H_2(g) + O_2(g) \xrightarrow{Pt} 2H_2O(l)$$

A catalyst is not consumed during a reaction. Therefore, it does not appear as a reactant in the chemical equation. Instead, the catalyst is often written above the yield arrow, as in the equation above.

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the lab. Make sure each group has ELLs of varied language proficiencies, so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Accept drawings, single words, or short phrases as answers to the questions. Have students copy the written work completed by more proficient students for future reference.

INTERMEDIATE: LOW/HIGH Create and distribute a chart with three columns, titled "tight," "loose," and "loose fibers" for students to record their observations.

ADVANCED: LOW/HIGH Have students assist and/or edit the work of classmates with lower language proficiency.

Interpret Graphs

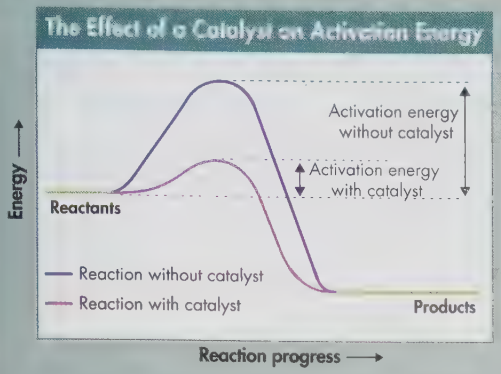


Figure 18.9 A catalyst lowers the activation-energy barrier for a reaction. With a lower barrier, more particles have enough energy for a successful collision.

a. Read Graphs How does using a catalyst change the amount of energy needed for products to form?

b. Make Generalizations Does the catalyst change the amount of energy released in the reaction?

c. Compare Along which of the two reaction paths are reactants converted more rapidly to products?

Hint: The reactant particles must have an energy equal to or greater than the activation energy to be converted to products.

Normal body temperature is only about 37°C. Your body needs to maintain this temperature to avoid damage to cells. At 37°C, reactions in the body would be too slow without catalysts. The catalysts that increase the rates of biological reactions are called enzymes. When you eat a meal containing protein, enzymes in your digestive tract help break down the protein molecules in a few hours. Without enzymes, the digestion of protein at 37°C would take many years!

An **inhibitor** is a substance that interferes with the action of a catalyst. Some inhibitors work by reacting with, or "poisoning," the catalyst itself. Thus, the inhibitor reduces the amount of catalyst available for a reaction. Reactions slow or even stop when a catalyst is poisoned.

18.1 LessonCheck

1. **Explain** How can you express the rate of a chemical reaction?
2. **Identify** List the four factors that can influence the rate of a chemical reaction.
3. **Describe** A thin, 0.2-mol sheet of zinc is completely converted to zinc oxide (ZnO) in one month. How would you express the rate of conversion of the zinc?
4. **Summarize** Does every collision between reacting particles lead to products? Explain.
5. **Relate Cause and Effect** Food stored in a refrigerator can stay fresh for long periods. Why does the same food stored at room temperature quickly spoil?

BIGIDEA MATTER AND ENERGY

6. Make a Venn diagram with two circles. Label one Matter and the other Energy. Choose a location in the diagram for each factor that can influence the rate of a reaction. Write a paragraph explaining your choices.

Lesson Check Answers

1. The rate of a chemical reaction is the amount of reactant changing per unit of time.
2. temperature, concentration, particle size, use of a catalyst
3. Rate = 0.2 mol Zn/month
4. No, the collision must have sufficient energy to break and form bonds.
5. Chemical reactions involved in food spoilage occur faster at higher temperatures because more energy is available.
6. **BIG**IDEA Concentration and particle size should be in the circle labeled *Matter* because each of these factors increase the reactant itself that is available for collisions. Temperature and catalysts should be in the circle labeled *Energy* because each of these factors manipulate the energy of the reactant or the energy of the activated complex, respectively.

Explain

USE VISUALS Direct students to Figure 18.9. **Ask** How would adding an inhibitor affect both graphs? *(The activation energy would be higher than the one shown in the graph for the reaction with a catalyst, but the inhibitor would have no effect on the reaction without a catalyst.)*

APPLY CONCEPTS Explain that home cooks often use inhibitors to poison catalysts on purpose. Have students consider what happens to the color of an apple after it is sliced and left exposed to air. *(The cut surfaces turn brown.)* Explain that the color change is the result of oxidation. The cut cells of the apple release an enzyme that increases the rate of oxidation. In order to prevent an apple from oxidizing, you would want to apply an inhibitor, such as ascorbic or citric acid, to the exposed surface.

Evaluate

Informal Assessment

Direct students' attention to Figure 18.5. Challenge students to use the activated complex theory to explain why hydrogen and oxygen do not react at room temperature but do combine explosively in the presence of a spark or flame. *(The explosive reaction indicates that the product—water—has less energy than the reactants. The reaction does not occur at room temperature because the reaction has a very high activation energy.)* Then have students complete the 18.1 Lesson Check.

Reteach

Have students revisit the section on Factors Affecting Reaction Rates. Remind students that chemical changes occur as a result of individual reactions between particles. Therefore, factors that affect collisions between particles are the factors that influence the rate of reaction. Help students to create and complete a table showing the relationship between increasing and decreasing each factor and the effect on the number of collisions. For visual learners, sketch example graphs of the activation complex for each of the four factors.

Answers

INTERPRET GRAPHS

a. It lowers the activation energy.
b. no
c. the line for reaction with a catalyst

CHEMISTRY & YOU

Draw students' attention to the diagrams and their labels. Pose the following question to students: *Why do you think catalytic converters work better in gasoline engines than diesel engines for reducing nitrogen oxides?* You may need to guide students in the following ways:

- Gasoline exhaust has a higher temperature than diesel exhaust.
- Diesel fuel contains sulfur, which can poison the catalyst in the converter.
- Catalytic converters need high temperatures to properly reduce nitrogen oxides.

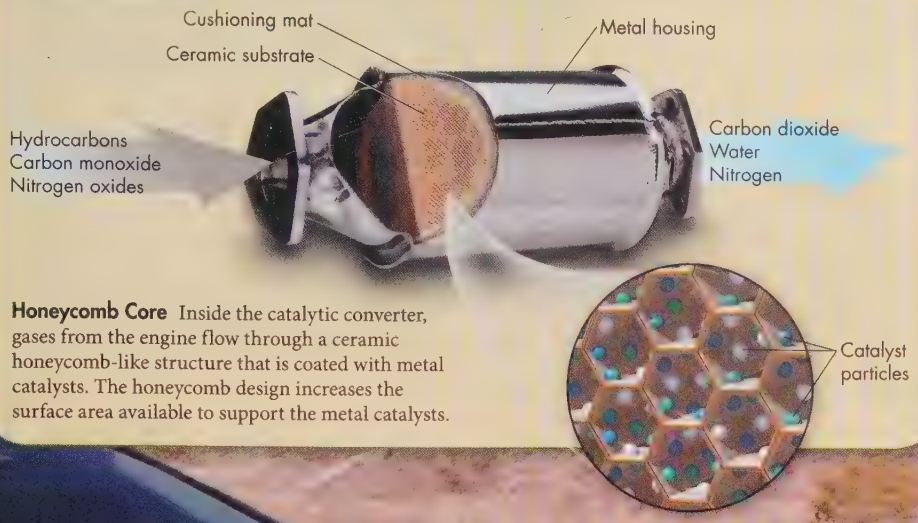
CHEMISTRY & YOU: TECHNOLOGY

Catalytic Converters

Vehicles that run on fossil fuels are a major source of air pollution. One technology that significantly reduces air pollution caused by vehicles is called a catalytic converter. The device keeps pollutants from being released into the air by converting them into less-harmful emissions. A typical catalytic converter is capable of eliminating about 98 percent of a vehicle's pollution—unreacted hydrocarbons, carbon monoxide, and nitrogen oxides. Precious metals such as platinum, palladium, and rhodium are catalysts for the reactions that occur inside the converter.

1 Engine When a car engine burns fuel, it produces gases that are bad for the environment, such as unreacted hydrocarbons, carbon monoxide, and nitrogen oxides.

3 Exhaust Pipe The less-harmful emissions—mainly carbon dioxide, water, and nitrogen—are then released through the exhaust pipe.



2 Catalytic Converter The catalytic converter is installed in the exhaust line. A pipe goes in one end of the converter from the engine, while another pipe leads out of the converter to the exhaust.

21st Century Learning To be successful in the 21st century, students need skills and learning experiences that extend beyond subject matter mastery. The following project helps students build the following 21st Century Skills: *Global Awareness*; *Civic Literacy*; *Critical Thinking and Problem Solving*; *Communication and Collaboration*; *Information, Media, and Technology Literacy*; *Initiative and Self-Direction*; and *Productivity and Accountability*.

ENVIRONMENTAL DEFENSE States have laws that require catalytic converters in all vehicles, but the details and penalties of the laws vary. Pose the following challenge to your students. *You have been asked to serve as an expert on a taskforce convened by the EPA to revise and toughen rules regarding installation of aftermarket catalytic converters. Create a slide presentation for the taskforce that does the following:*

- explains the history of the development of the first automotive catalytic converter
- provides a clear description of how catalytic converters work
- explains the difference between the three general types of converters and the dangers of installing the wrong converter on a vehicle
- summarizes the environmental impact of catalytic converter use and disposal.

A Closer Look

Honeycomb Core Inside the catalytic converter, gases from the engine flow through a ceramic honeycomb-like structure that is coated with metal catalysts. The honeycomb design increases the surface area available to support the metal catalysts.

Take It Further

1. Infer Why does maximizing the surface area of the core increase the effectiveness of a catalytic converter?

2. Describe In a catalytic converter, platinum catalyzes a combination reaction between oxygen and carbon monoxide to form carbon dioxide. Write a balanced chemical equation for this catalyzed reaction.

3. Research a Problem Cars that are equipped with catalytic converters are designed to run on unleaded gasoline. A single tank of leaded gasoline can seriously impair the performance of the converter. Conduct an Internet search to determine the reason. Write a short paragraph to summarize what you learn.

Differentiated Instruction

L1 STRUGGLING STUDENTS Work together to draw a flow chart on the board to depict the steps involved in the production and conversion of exhaust from a vehicle. Have each student name a step in the process and explain why it is important.

LPR LESS PROFICIENT READERS Have students draw a T-chart in their vocabulary notebooks. In the left column, have them list five unfamiliar words in the feature. Have students use a dictionary to define the words and write each definition in the right column of the table, along with a symbol or drawing for additional clarity.

ELL ENGLISH LANGUAGE LEARNERS Write the words *catalytic* and *catalyst* on the board. Underline the similar parts of the words. Explain that the word *catalyst* is a noun, and the word *catalytic* is an adjective, which is a word that describes a noun. Lead students in discussing how the meanings of the words are related.

Explain

USE VISUALS Have students study the picture of the catalytic converter and its honeycomb core. **Ask** What do you think are some reasons for using a honeycomb design? *(It provides a strong surface through which the exhaust easily can flow. The design provides a way to expose a large amount of the catalysts to the exhaust.)* **Ask** Do you think the precious metals get used up so that the catalytic converter has to be replaced? Why or why not? *(No; Because they are catalysts, the precious metals participate in the chemical reactions that convert the exhaust, but they are neither reactants nor products of the reactions. They do not get used up.)*

Extend

Connect to ENVIRONMENTAL SCIENCE

Catalytic converters greatly reduce the hydrocarbon, carbon monoxide, and nitrogen oxide emissions from a vehicle. However, they increase the emission of carbon dioxide, which may contribute to global warming. Global warming is the gradual increase in Earth's average temperature. Excess carbon dioxide, along with water vapor, methane, ozone, and other greenhouse gases in the atmosphere, contribute to global warming by trapping some of the sun's radiation that would otherwise escape into space. Consequences include melting glaciers, severe droughts, rising sea levels, an increase in the intensity of hurricanes, and destruction of coral reefs. The addition of catalytic converters significantly reduces the air pollution from vehicles, but other technologies are needed to avoid the effect on global warming. Ask students to research current statistics on global numbers of gasoline- and diesel-powered vehicles on the world's roads, and the percentage of vehicular carbon dioxide emissions attributed to the five most populous countries.

Answers

TAKE IT FURTHER

1. It increases the frequency of particle collisions.
2. $\frac{1}{2}O_2(g) + CO(g) \rightarrow CO_2(g)$
3. The lead binds to the catalytic particles and inhibits their activity.

LESSON 18.2

Key Objectives

DESCRIBE the relationship between the value of the specific rate constant and the speed of a reaction.

DESCRIBE how most reactions progress from start to finish.

Additional Resources

- Reading and Study Workbook, Lesson 18.2
- Probeware Laboratory Manual
- Virtual Chemistry Labs

CHEMISTRY & YOU Have students read the opening text. Display a picture of the Pyrenees mountain range. Explain that the Tour's route is broken into a series of stages, many of which travel through the Pyrenees mountains. **Ask** How is the Tour de France bicycle race like the activation energy diagram for a complex chemical reaction? *(A series of chemical reactions may require more activation energy at some points and may release energy at other points.)*

Activate Prior Knowledge

Have students recall the four factors that can influence the rate of a chemical reaction. *(temperature, concentration, particle size, and the presence of a catalyst)* **Ask** How does the concentration of reactants affect the rate of a chemical reaction? *(The higher the concentration, the faster the reaction rate, and vice versa.)* Have students keep this in mind as they read this lesson.

Foundations for Reading

BUILD VOCABULARY Write the word *intermediate* on the board. Have students look up the prefix *inter- (between)* and the stem *mediate (middle)* and write a definition for the word in their own terms. Have students compare their definitions to the dictionary definition.

IN ACADEMIC STANDARDS for SCIENCE

C.7.5 Explain how the rate of a reaction is qualitatively affected by changes in concentration, temperature, surface area, and the use of a catalyst.

18.2 The Progress of Chemical Reactions

C.7.5 Factors affecting rate of reaction

CHEMISTRY & YOU

Q: *How is a bicycle race like a chemical reaction?* The Tour de France is one of the most famous bicycle races in the world. It is held from mid-July to early August every year. During the race, cyclists travel almost 4000 kilometers. At one stage of the race, riders must cross steep mountains with heights of 1900 meters or more. The riders need extra energy to ride through these steep mountains.

Key Questions

What is the relationship between the value of the specific rate constant, k, and the speed of a chemical reaction?

How do most reactions progress from start to finish?

Vocabulary

- rate law
- specific rate constant
- first-order reaction
- elementary reaction
- reaction mechanism
- intermediate

Rate Laws

What is the relationship between the value of the specific rate constant, k, and the speed of a chemical reaction?

The rate of a reaction depends in part on the concentrations of the reactants. Suppose there were a reaction with only one reactant and one product. You could write a simple equation for this reaction.

$$A \longrightarrow B$$

The rate at which A forms B can be expressed as the change in A (ΔA) with time, where $[A_1]$ is the initial molar concentration of A at time t_1 and $[A_2]$ is the molar concentration of A at a later time, t_2.

$$\text{Rate} = \frac{\Delta A}{\Delta t} = \frac{[A_2] - [A_1]}{t_2 - t_1}$$

The rate of disappearance of A is proportional to the concentration of A.

$$\frac{\Delta A}{\Delta t} \propto [A]$$

The proportionality can be expressed as the concentration of A, [A], multiplied by a constant, k.

$$\text{Rate} = \frac{\Delta A}{\Delta t} = k \times [A]$$

This equation is a **rate law,** an expression for the rate of a reaction in terms of the concentration of reactants. The **specific rate constant** (k) for a reaction is a proportionality constant relating the concentrations of reactants to the rate of the reaction. The value of the specific rate constant depends on the conditions of the reaction and is determined through experiments. **The value of the specific rate constant, *k*, in a rate law is large if the products form quickly; the value is small if the products form slowly.**

Focus on ELL

1 CONTENT AND LANGUAGE Write the words *order*, *elementary*, and *intermediate* on the board. Pronounce each word and ask students to repeat. Explain that these words have both common and scientific meanings. Show students how the common meaning of each word is related to its scientific meaning in relation to this lesson.

2 FRONTLOAD THE LESSON Provide a quick review of mathematical terminology such as *proportional, interpret, constant, slope, tangent, known,* and *unknowns* prior to explaining the rate laws. Explain that this lesson will use mathematics to quantify concepts learned in Lesson 18.1.

3 COMPREHENSIBLE INPUT During the evaluation step of Sample Problem 18.1, demonstrate mathematically that the concentration of Trial 2 is double that of Trial 1, and that the initial concentration of Trial 2 is four times that of Trial 1. When discussing reaction mechanisms, write the equations for the decomposition of nitrous oxide on the board and demonstrate step-by-step how to add the two equations together to attain the overall equation.

Interpret Graphs

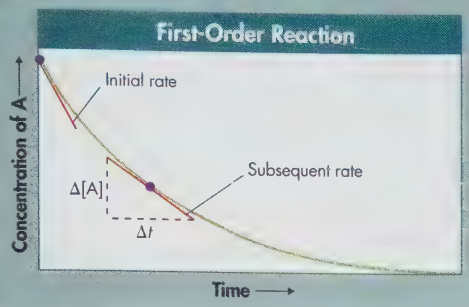


Figure 18.10 The graph shows how the concentration of a reactant changes during a first-order reaction.

a. Identify What are the independent and dependent variables?

b. Describe What happens to the concentration of reactant A over time?

c. Compare The short red lines (tangents) illustrate the reaction rates at two different points in the reaction. Which rate is faster—the *initial rate* or the *subsequent rate*?

Hint: The slope of the tangent to the curve at any point is equal to the rate at that point.

First-Order Reactions The order of a reaction is the power to which the concentration of a reactant must be raised to match the experimental data on concentration and rate. In a **first-order reaction,** the rate is directly proportional to the concentration of only one reactant. Assume the reaction A ⟶ B is an example of a first-order reaction. The reaction rate is proportional to the concentration of A raised to the first power: $[A]^1 = [A]$.

The graph in Figure 18.10 shows the progress of a first-order reaction. Over time, the rate of reaction decreases because the concentration of the reactant is decreasing. For a first-order reaction, if [A] is reduced by one half, the reaction rate is reduced by one half. The rate ($\Delta A/\Delta t$) at any point on the graph equals the slope of the tangent to the curve at that point.

Higher-Order Reactions In some reactions, two substances react to give products. One example is a double-replacement reaction. The general equation for a double-replacement reaction can be written as follows. The coefficients are represented by lowercase letters.

$$aA + bB \longrightarrow cC + dD$$

For the reaction of A with B, the rate of reaction is dependent on the concentrations of both A and B.

$$\text{Rate} = k[A]^x[B]^y$$

When each exponent in the rate law equals 1 (that is, $x = y = 1$), the reaction is said to be first order in A and first order in B. The overall order of a reaction is the sum of the exponents for the individual reactants. A reaction that is first order in A and first order in B is thus second order overall.

You might assume that the coefficients in a chemical equation and the exponents in the rate law for that reaction would always be the same. If your assumption were true, you could use the coefficients of the reactants to find the order of a reaction. For most reactions, however, the exponents in the rate law and the coefficients in the equation do not correspond. Most reactions are more complex than the reactions used in the examples. Thus, the actual order of a reaction must be determined by experiment.

UbD Check for Understanding

What is the relationship between the value of the specific rate constant *k* and the speed of a chemical reaction?

Assess students' understanding by asking them to consider what can be implied if the magnitude of the rate constants from two different chemical reactions is known? *(Sample answer: Whether the products formed quickly or slowly.)*

ADJUST INSTRUCTION If students are having trouble answering, have them re-read the section on Rate Laws. Then, provide students with specific rate constants for two reactions, such as a reaction with and without a catalyst added, for comparison.

READING STRATEGY Have students create a main ideas and details chart with the orange and blue headings. Have them complete their charts as they read the lesson.

Explain

Rate Laws

APPLY CONCEPTS Point out that the rate law contains a rate constant, *k,* which is specific to a reaction. Demonstrate how to set up the rate equation for a chemical reaction such as the formation of water from hydrogen and oxygen. Emphasize that this constant only applies to the concentration of the reactants over time, not the products.

USE MODELS Review linear functions with the class. **Ask** What ratio do you use to the slope of a line? *(the slope of a line is the ratio of the rise* (y) *to the run* (x).*)* Demonstrate how to calculate the slope for several lines on a coordinate grid using the concept of rise over run between two points of a given line.

USE VISUALS Ask students to examine the title and the labels on Figure 18.10. **Ask** As time increases, what happens to the concentration of reactant A? *(it decreases)* Discuss the effect of concentration on reaction rate. Explain how this relationship can be expressed quantitatively. Show students how they can use the relationship between concentration and time to predict the actual reaction rate as well as to describe the step-by-step mechanism by which the reaction occurs. Make sure students understand that the the rate *must* be calculated; it cannot be "read" directly from the graph.

INTERPRET DIAGRAMS Direct students again to Figure 18.10. **Ask** Is the graph a linear function? Explain. *(No; the graph is not a straight line.)* If the relationship in the graph formed a straight line, how would you find the slope? *(rise over run, or the ratio of* ΔA *to* Δt*)* Show students that to find the rate of reaction at a specific instant during the reaction, they can draw a line tangent to the curve at the point on the line associated with that instant. Then they can find the slope of that line to determine the rate at that specific time during the reaction. Demonstrate this concept by showing students how to calculate the rates of reaction for the two points shown in Figure 18.10.

Answers

INTERPRET GRAPHS

a. independent: time; dependent: relative concentration of A

b. It decreases.

c. initial rate

Explain

START A CONVERSATION Point out that most reactions are more complex than the one-step reactions used as examples in the text. In most cases, reaction order cannot be predicted solely on the basis of a balanced equation; it must be determined experimentally. This is because the rate depends primarily on the slowest step in the reaction mechanism.

Misconception Alert

Students may confuse the as exponent that represents the reactant's reaction order with the reactant's stoichiometric coefficient because the same lowercase letter is used to represent both in the generic chemical and rate equations in the text. It may be helpful to provide students with an example first-order reaction in which the rate and the coefficient for the reactant are *not* equal.

Sample Practice Problem

A first-order reaction has an initial rate of 0.6 mol/L·s. What is the rate when one-third of the starting material remains? *(0.2 mol/L·s)* When one-eighth of the starting material remains? *(0.075 mol/L·s)*

SampleProblem 18.1

Finding the Order of a Reaction From Experimental Data

Consider the reaction $aA \longrightarrow B$. The rate law for this reaction is Rate $= k[A]^x$. From the data in the table, find the order of the reaction with respect to A and the overall order of the reaction.

Trial	Initial concentration of A (mol/L)	Initial rate (mol/(L·s))
1	0.050	3.0×10^{-4}
2	0.10	12×10^{-4}
3	0.20	48×10^{-4}

KNOWNS
$[A]_1 = 0.050$ mol/L
$[A]_2 = 0.10$ mol/L
$Rate_1 = 3.0 \times 10^{-4}$ mol/(L·s)
$Rate_2 = 12 \times 10^{-4}$ mol/(L·s)

UNKNOWNS
Order of reaction with respect to A = ?
Overall order of the reaction = ?

1 Analyze **List the knowns and the unknowns.** Use the first two trials to calculate the order and the third to evaluate your answer.

2 Calculate **Solve for the unknowns.**

Start with the rate law for each initial concentration of A.

$$Rate_1 = k[A_1]^x$$
$$Rate_2 = k[A_2]^x$$

The rate law of the reaction and the specific rate constant, k, is the same for any initial concentration of A.

Divide the second expression by the first expression.

$$\frac{Rate_2}{Rate_1} = \frac{\cancel{k}[A_2]^x}{\cancel{k}[A_1]^x} = \left(\frac{[A_2]}{[A_1]}\right)^x$$

Substitute the known quantities into the equation.

$$\frac{12 \times 10^{-4}\ \cancel{mol/(L \cdot s)}}{3.0 \times 10^{-4}\ \cancel{mol/(L \cdot s)}} = \left(\frac{0.10\ \cancel{mol/L}}{0.050\ \cancel{mol/L}}\right)^x$$

$$4.0 = 2.0^x$$

Determine the value of x.

$$x = 2$$

The reaction is second order in A.
Since A is the only reactant, the reaction must be second order overall.

3 Evaluate **Does this result make sense?** If the reaction was first order in A, doubling the concentration would double the rate. However, $Rate_2$ is *four* times $Rate_1$. So the reaction is second order for A and second order overall because A is the only reactant. As a further check, look at what happens to the rate when the concentration doubles again from 0.10 mol/L to 0.20 mol/L.

7. Suppose the initial rate for a first-order reaction is 0.5 mol/(L·s). What is the rate when half the reactant remains? When one fourth of the reactant remains?

8. Show that the unit of k for a first-order reaction is a reciprocal unit of time, such as a reciprocal second (s^{-1}). Begin with the expression Rate $= k[A]$.

To do Problem 8, isolate k, and then substitute the units for rate and concentration.

Foundations for Math

ISOLATING A VARIABLE Tell students that solving rate problems often involves solving for a variable in an exponent. Explain that to isolate a variable that is an exponent, they must use natural logarithms (natural log, or ln).

To solve for a in **Sample Problem 18.1,** begin by taking the natural log of both sides of the equation $4.0 = 2^a$:

$$\ln(4.0) = \ln(2^a)$$

Use the properties of logs to pull a out of the exponent by rewriting the equation as:

$$a \ln 2 = \ln 4.0$$

Divide both sides of the equation by ln 2 to isolate a:

$$\frac{a \ln 2}{\ln 2} = \frac{\ln 4.0}{\ln 2}$$

Solving for a gives $a = \ln 4.0/\ln 2 = 1.38629/0.69314 = 2.00001$, which rounds to 2. So $a = 2$. Remind students that natural log is not the same as antilog (inverse log). Help them locate the natural log key on their calculators.

Reaction Mechanisms

How do most reactions progress from start to finish?

Balanced equations are extremely useful. They tell you what reactants are present at the start of a reaction and what products are present at the end. What a balanced equation does not tell you is *how* the reaction occurred. For example, plants use photosynthesis to capture and store light energy. The process can be summarized by stating that carbon dioxide and water yield simple sugars and oxygen. However, the process of photosynthesis is not as simple as this summary implies.

One-Step and Multistep Reactions If you had enough data, you could graph all the energy changes that occur as reactants are converted to products in a chemical reaction. Such a graph is called a reaction progress curve, or reaction profile. For an elementary reaction, you would get a graph like the ones in Figure 18.5. An **elementary reaction** is a reaction in which reactants are converted to products in a single step. This type of reaction has only one activation-energy peak and one activated complex.

Most chemical reactions consist of two or more elementary reactions. The series of elementary reactions or steps that take place during the course of a complex reaction is called a **reaction mechanism.** Figure 18.11 shows a reaction progress curve for a complex chemical reaction. The graph has a peak for each activated complex and a valley for each intermediate.

An **intermediate** is a product of one step in a reaction mechanism and a reactant in the next step. An intermediate has a more stable structure and a longer lifetime than an activated complex. Yet, an intermediate is reactive enough to take part in the next step. Intermediates do not appear in the overall chemical equation for a reaction.

CHEMISTRY & YOU

Q: *In the mountain stage of the Tour de France, a rider encounters a series of peaks and valleys. In terms of energy, how does the trip through the mountains compare to what happens during a multistep reaction?*

InterpretGraphs

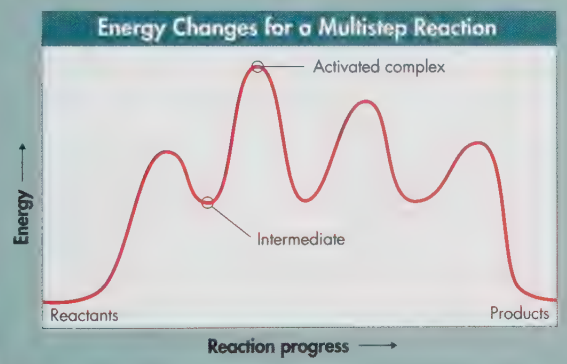

Figure 18.11 A reaction progress curve shows an activation-energy peak for each elementary reaction. Valleys indicate the formation of intermediates.

a. Read Graphs How many steps are in the reaction mechanism represented by this graph?

b. Read Graphs How many intermediates are formed as the reaction progresses?

c. Predict What effect might a catalyst have on the height of the peaks and depth of the valleys in this curve?

Hint: To answer part c, refer back to Figure 18.9.

Differentiated Instruction

ELL ENGLISH LANGUAGE LEARNERS Speak clearly and slowly when reading the symbols used in the equations aloud. Be sure to phrase the relationships using precise mathematical verbiage so not to confuse students going forward. Define the math words and symbols as they appear. Add these terms to the word wall.

L1 STRUGGLING STUDENTS Point out that the units of concentration of a reactant or product are often given in moles per unit volume. However, clarify that concentration is not dependent on the entire volume of the reaction.

L3 ADVANCED STUDENTS Challenge students to compare and contrast the concepts of average rate and instantaneous rate. Ask students to describe which rate is best suited to depict the progress of a chemical reaction and why.

Reaction Mechanisms

APPLY CONCEPTS Explain that even complex reactions occur as a series of simple steps. Each step usually involves the collision of no more than two different particles. Use the reaction between hydrogen and bromine as an example. Show students that the overall reaction, $H_2 + Br_2 \rightarrow 2HBr$, occurs as a sequence of three elementary steps:

$Br_2 \rightarrow 2Br$

$Br + H_2 \rightarrow HBr + H$

$H + Br \rightarrow HBr$

INTERPRET DIAGRAMS Direct students' attention to Figure 18.11 and explain that the activation energy of a reaction, determined experimentally, is plotted versus time or reaction progress. Remind students that the independent variable is shown on the *x*-axis and the dependent variable is shown on the *y*-axis. **Ask** Why does this graph have more hills and valleys than the graphs in Lesson 18.1? *(This graph is a multi-step reaction, but the graphs in Lesson 18.1 were only one-step graphs.)* Explain that for each step in a reaction there must be enough activation energy for the reaction to proceed. **Ask** Is the activation energy for each step in the multi-step reaction shown in the graph equal to all the other activation energies in the reaction? Explain. *(No; the peaks of the hills all correspond to different* y*-values.)* **Ask** Does each step in the reaction take the same amount of time? How do you know? *(No; the change in the* x*-values is not constant.)*

MAKING CONNECTIONS Explain that displaying the activation energy data in a graph provides a more complete picture of the reaction process than a table of data. Relate this concept to piece-wise or step functions learned in algebra.

Answers

7. 0.25 mol/ (L · s); 0.125 mol/ (L · s)

8. Rate = k[A]; rate is expressed in units of mol/(L · s). [A] is expressed in units of mol/L.
k = Rate/[A]
$k = 1/s = s^{-1}$

FIGURE 18.11

a. four

b. three

c. It would lower the activation energy for the slowest step in the reaction mechanism.

Extend

Explain to students that intermediate products often react with reactants during a multi-step reaction to produce other intermediates or final products. Tell students that one reaction in which this occurs is the thermal decomposition of nitryl chloride (NO_2Cl) to NO_2 and Cl_2. This process is believed to occur in two steps. Challenge students to suggest a possible reaction mechanism for this reaction.

($NO_2Cl \rightarrow NO_2 + Cl$

$NO_2Cl + Cl \rightarrow NO_2 + Cl_2$)

Evaluate

Informal Assessment

Write on the board the two-step reaction mechanism for the production of NO_2F from NO_2 and F_2.

$NO_2 + F_2 \rightarrow NO_2F + F$ (slow)

$NO_2 + F \rightarrow NO_2F$ (fast)

$2\ NO_2 + F_2 \rightarrow 2NO_2F$

Ask students to construct the reaction rate equation for the reaction mechanism shown. *(The first step of the reaction is the slowest step so it is the rate-determining step. The rate law is rate = $k[NO_2][F_2]$.)* Then have students complete the 18.2 Lesson Check.

Reteach

Have students review their notes and Figures 18.10 and 18.11 in the lesson to identify the difference between rate determination and the calculation of an equilibrium constant, which can be determined from the overall reaction. Scaffold learning by showing students how to predict the reaction rate with a simple one-step reaction with one reactant, then two reactants, and then a multi-step reaction.

Rate-Determining Steps In a multistep chemical reaction, the steps do not all progress at the same rate. One step will be slower than the others. The slowest step will determine, or limit, the rate of the overall reaction. As an analogy, think about shopping in a supermarket. First, you collect the items you want to buy. Then, you go through the checkout line and pay for your purchases. If you are buying many items, the first step is likely to take longer than the second. If you are buying only one or two items, getting through the checkout line may be the slower step.

Consider the reaction mechanism for the decomposition of nitrous oxide (N_2O). Experiments have shown that the mechanism consists of the two steps shown below.

$$\text{Step 1: } N_2O(g) \longrightarrow N_2(g) + O(g) \text{ (slow)}$$

$$\text{Step 2: } N_2O(g) + O(g) \longrightarrow N_2(g) + O_2(g) \text{ (fast)}$$

$$\text{Overall: } 2N_2O(g) \longrightarrow 2N_2(g) + O_2(g)$$

In the first step, nitrous oxide decomposes into nitrogen gas and oxygen atoms. The oxygen atoms are an intermediate. They react with nitrous oxide in the second step to produce nitrogen molecules and oxygen molecules. The reaction in the second, faster step cannot occur until the first, slower step occurs. Therefore, the rate of the overall reaction depends on the rate of the first step. To increase the rate of the overall reaction, you would need to increase the rate of the first step. Thus, for the decomposition of nitrous oxide, the first step is called the *rate-determining step.*

When the equations for the two steps are summed, the oxygen atoms disappear. This example illustrates why you cannot use the overall chemical equation for a complex reaction to determine the reaction mechanism. Instead, the mechanism must be determined through experiments.

18.2 LessonCheck

9. Explain What does the size of the specific rate constant, k, indicate about the rate of a chemical reaction?

10. Summarize How do most chemical reactions progress from start to finish?

11. Describe How can you use a graph of reactant concentration versus time to determine the rate of a chemical reaction?

12. Draw Conclusions Consider the one-step reaction $aA \longrightarrow B$, with the following rate law: Rate = $k[A]^x$. When the initial concentration of A is increased from 0.35 mol/L to 0.70 mol/L, the initial rate increases from 1.6 mol/(L·s) to 3.2 mol/(L·s). What is the order of the reaction with respect to A? What is the overall order of the reaction?

13. Apply Concepts The rate law for the following reaction is first order in NO and O_3, and second order overall.

$$NO(g) + O_3(g) \longrightarrow NO_2(g) + O_2(g)$$

Write the rate law for this reaction.

14. Explain What is an elementary reaction, and how is it related to a reaction mechanism?

15. Classify Is an intermediate a reactant or a product? Explain.

16. Infer Look at the equation for the reaction of nitric oxide and oxygen. Do you think this is a single-step reaction or a multistep reaction? Use what you know about collision theory to explain your answer.

$$2NO(g) + O_2(g) \longrightarrow 2NO_2(g)$$

Lesson Check Answers

9. The larger the specific rate constant, k, the faster the reaction.

10. Most reactions consist of two or more elementary reactions, each resulting in the formation of an intermediate.

11. The rate at any given point on the graph is determined by calculating the slope of the tangent to the curve at that point.

12. first order in A; first order overall

13. Rate = $k[NO][O_3]$

14. An elementary reaction is a reaction in which reactants are converted to products in a single step. A reaction mechanism is a series of elementary reactions that comprise a complex chemical reaction.

15. Both, it is a product in one step in a reaction mechanism and a reactant in the next step.

16. multistep; To proceed in a single-step reaction, three molecules would have to collide in the correct orientation, which is unlikely.

18.3 Reversible Reactions and Equilibrium

C.7.6 Reversible reactions

CHEMISTRY & YOU

Q: *How did chemists help farmers produce more food?* Fertilizers can increase the amount of a crop per unit of land. Most fertilizers contain ammonia or nitrogen compounds made from ammonia. For years, scientists tried and failed to develop an efficient way to produce ammonia from nitrogen and hydrogen. In the early 1900s, two German chemists, Fritz Haber and Karl Bosch, found the solution.

- equilibrium constant

Reversible Reactions

What happens at the molecular level in a chemical system at equilibrium?

Based on the chemical equations you have seen, you may have inferred that chemical reactions always progress in one direction. This inference is not true. Some reactions are reversible. A **reversible reaction** is one in which the conversion of reactants to products and the conversion of products to reactants occur at the same time. Here's an example of a reversible reaction.

Forward reaction: $2SO_2(g) + O_2(g) \longrightarrow 2SO_3(g)$

Reverse reaction: $2SO_2(g) + O_2(g) \longleftarrow 2SO_3(g)$

In the first reaction, which is read from left to right, sulfur dioxide and oxygen produce sulfur trioxide. In the second reaction, which is read from right to left, sulfur trioxide decomposes into oxygen and sulfur dioxide. The first reaction is called the forward reaction. The second is called the reverse reaction. The two equations can be combined into one using a double arrow. The double arrow tells you that the reaction is reversible.

$$2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$$

Sulfur dioxide — Oxygen — Sulfur trioxide

Figure 18.12 models what is happening at the molecular level.

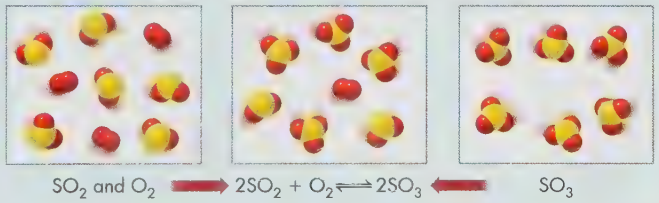

Figure 18.12 Opposite Reactions Molecules of SO_2 and O_2 react to give SO_3. Molecules of SO_3 decompose to give SO_2 and O_2.

KINETIC ART *See reversible reactions animated online.*

Focus on ELL

1 CONTENT AND LANGUAGE Write the word *equilibrium* on the board. Display a picture of a pan balance, and explain that the Latin root of *equilibrium*, *libra*, means "balance." Have students use word-analysis strategies to determine the meaning of the prefix *equi-*, and write their own definitions of *equilibrium*.

2 FRONTLOAD THE LESSON Display a reversible jacket, or ask a student with one to show how it can be worn with either side facing out. Then ask students to think about how a car can go forward, but also can go in reverse. Tell students that they will explore how reactions can also be reversible as they work through this lesson.

3 COMPREHENSIBLE INPUT Show students a recorded gymnastics competition or pictures of gymnasts in various poses displaying the concept of equilibrium. Point out the concept of forward/reversible with the forward/backward motion of a gymnast.

LESSON 18.3

Key Objectives

DESCRIBE what happens at the molecular level in a chemical system at equilibrium.

IDENTIFY the three stresses that can cause a change in the equilibrium position of a chemical system.

DESCRIBE what the size of an equilibrium constant indicates about a system at equilibrium.

Engage

CHEMISTRY & YOU Point out that the two reactants involved in production of ammonia are gases. **Ask:** Based on what you have previously learned about gases and reaction rates, what conditions involving the reaction of gaseous nitrogen and hydrogen, if altered, might affect the reaction? *(altering temperature and pressure)*

Access Prior Knowledge

Briefly review the ideal gas law and ask students to explain how real gases differ from ideal gases. Then, ask students how a reaction rate is determined and the factors that can affect the reaction rate.

IN ACADEMIC STANDARDS for SCIENCE

C.7.6 Write equilibrium expressions for reversible reactions.

Foundations for Reading

BUILD VOCABULARY Have students use the LINCS strategy to learn what Le Châtelier's principle means. In LINCS exercises, students list what they know about each term, imagine a picture that describes the term, note a reminding "sound-alike" word, connect the terms to the sound-alike word by making up a short story, and then perform a brief self-test.

READING STRATEGY Ask students to rewrite the headings of each section as *how, why,* and *what* questions. Tell students to consider these questions as they read the corresponding information.

Explain

Reversible Reactions

USE VISUALS Have students examine Figure 18.12. Point out that this visual shows the reaction of the reactants and the decomposition of the products. **Ask:** Does the reaction continue when the products and reactants are at equilibrium? *(Yes; reactants change into products, and products reform into reactants, but their net amounts stay the same.)*

CRITICAL THINKING Have students study Figure 18.12 again. **Ask** If you changed the volume, pressure, or temperature of the reaction, would the graphs change? Explain. *(The concentrations of both the reactants and products would change because changing the volume of a gas's container, its pressure, and its temperature can affect concentration.)*

Establishing Equilibrium What actually happens when sulfur dioxide and oxygen gases are mixed in a sealed container? The forward reaction begins at a given rate. Because no sulfur trioxide is present at the start, the initial rate of the reverse reaction is zero. As sulfur trioxide forms, however, the decomposition of sulfur trioxide begins. The rate of the reverse reaction is slow at first. Its rate increases as the concentration of sulfur trioxide increases. At the same time, the rate of the forward reaction decreases because sulfur dioxide and oxygen are being used up. Eventually, sulfur trioxide is decomposing as fast as sulfur dioxide and oxygen are combining. When the rates of the forward and reverse reactions are equal, the reaction has reached a state of balance called **chemical equilibrium.**

Look at the graphs in Figure 18.13. The graph on the left shows the progress of a reaction that starts with initial concentrations of SO_2 and O_2, but with zero SO_3. The graph on the right shows the progress of a reaction that begins with an initial concentration of SO_3 and zero concentrations for SO_2 and O_2. Notice that after a certain time, equilibrium is achieved and all the concentrations remain constant. The amount of SO_3 in the equilibrium mixture is the maximum amount that can be produced by this reaction under the conditions of the reaction.

Conditions at Equilibrium The unchanging amounts of SO_2, O_2, and SO_3 in the reaction mixture at equilibrium might cause you to think that both reactions have stopped. This is not the case. Chemical equilibrium is a dynamic state. **At chemical equilibrium, both the forward and reverse reactions continue, but because their rates are equal, no net change occurs in the concentrations of the reaction components.** Figure 18.14 provides an analogy for how an equilibrium is established and maintained.

Interpret Graphs

$$2SO_2 + O_2 \longrightarrow 2SO_3$$

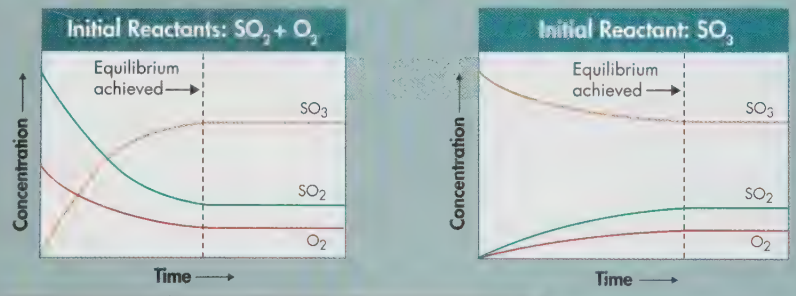

Figure 18.13 These graphs show how the concentrations of O_2, SO_2, and SO_3 vary as each system reaches equilibrium.
a. Identify Where can you find the initial concentrations for each component? Where can you find the equilibrium concentrations?
b. Read Graphs Which gas is most abundant at equilibrium?
c. Make Generalizations Does the starting point of a reversible reaction affect the equilibrium concentrations of components? Explain.

Hint: Compare the equilibrium concentrations between the two graphs.

UbD Check for Understanding

What happens at the molecular level in a chemical system at equilibrium?

Instruct students to write a brief statement explaining the information they know about a reaction if the reaction is reversible *and* at chemical equilibrium.

ADJUST INSTRUCTION If students are having difficulty writing their statements, ask them to read the text about conditions at equilibrium and organize their thoughts with a bulleted list. Then have students revise their statements.

Figure 18.14 Equilibrium Positions The up and down escalators in a store could represent a forward reaction and its reverse reaction. **a.** When the store opens, only the forward reaction occurs as shoppers head to the second floor. **b.** Equilibrium is reached when the rate at which shoppers move from the first floor to the second is equal to the rate at which shoppers move from the second floor to the first.
Use Analogies ***Do the number of people on each floor have to be equal at equilibrium? Explain.***

Concentrations at Equilibrium Although the rates of the forward and reverse reactions are equal at equilibrium, the concentrations of the components usually are not. Look again at Figure 18.13. At equilibrium, the concentration of SO_3 is much greater than the concentrations of SO_2 and O_2. The relative concentrations of the reactants and products at equilibrium mark the **equilibrium position** of a reaction. This position tells you whether the forward or reverse reaction is more likely to happen. Suppose a single reactant, A, forms a single product, B. If the equilibrium mixture contains 1 percent A and 99 percent B, then the formation of B is said to be favored.

$$\underset{1\%}{A} \rightleftharpoons \underset{99\%}{B}$$

If the mixture contains 99 percent A and 1 percent B at equilibrium, then the formation of A is favored.

$$\underset{99\%}{A} \rightleftharpoons \underset{1\%}{B}$$

Notice that the equilibrium arrows are not of equal length. The longer of the two arrows indicates which reaction is favored and whether reactants or products will be more common at equilibrium.

In principle, almost all reactions are reversible to some extent under the right conditions. In practice, one set of components is often so favored at equilibrium that the other set cannot be detected. When no reactants can be detected, you can say that the reaction has gone to completion, or is irreversible. When no products can be detected, you can say that no reaction has taken place. Reversible reactions occupy a middle ground between the extremes of irreversibility and no reaction.

Differentiated Instruction

L1 LESS PROFICIENT READERS Have students identify and list words in the lesson with which they are having difficulty. Assist students in using context clues to determine the meaning of the listed words.

ELL ENGLISH LANGUAGE LEARNERS Avoid using the terms *unbalanced* and *balanced* to convey disequilibrium and equilibrium, as students may confuse the meaning with balanced reactions. Act out the concept of equilibrium by asking students to stand with one foot extended in front of them, and arms extended to the side for as long as possible. Point out those students who are steady and not moving as students at equilibrium.

L3 ADVANCED STUDENTS Ask students to determine what is meant by a static reaction and a dynamic reaction. Have students explain to the class why a reaction at equilibrium is said to be a dynamic reaction.

APPLY CONCEPTS Point out that, in many cases, the concept of reactants turning into products, as described by a chemical equation, is an oversimplification. Explain that many reactions reach an equilibrium state in which the reaction mixture contains both reactant and product particles. The percent of reactants converted to products varies considerably. Show students that when hydrogen and oxygen combine to form water, for example, nearly all of the molecules react, as opposed to the reaction of hydrogen and nitrogen to form ammonia, in which the percent of reactants converted to product is much smaller. Stress that equilibrium refers to the rates of the forward or reverse reactions, not to the quantities of reactants and products.

CRITICAL THINKING As a class, discuss how the concepts of endothermic and exothermic reactions may relate to the concept of reversible reactions.

Extend

Connect to PHYSICS Ask students to research Newton's Third Law—the Law of Reciprocal Actions—and create a representation to show how this law helps to explain the concept of chemical equilibrium.

Answers

INTERPRET GRAPHS

a. Initial concentrations are at the far left, and equilibrium concentrations are at the far right.

b. SO_3

FIGURE 18.14 No, the numbers can be different but the number of shoppers moving between floors must be the same.

Explain

Factors Affecting Equilibrium: Le Châtelier's Principle

MAKE A CONNECTION Ask students to recall the formation of banana oil demonstration in Lesson 18.1. Write the general word equation for the formation of an ester on the board (organic acid + alcohol → ester + water). Add a reverse arrow to show the possibility of the opposite reaction. Remind students that the reaction was effective in the test tube to which anhydrous calcium sulfate had been added. Calcium sulfate reacted with water to form a hydrate, which limited the reverse reaction by removing a product.

Explore

Teacher Demo

PURPOSE Students observe the reaction with the greatest yield.

MATERIALS 10 mL ethanoic acid, 10 mL isoamyl alcohol, 2 test tubes, anhydrous calcium sulfate, concentrated sulfuric acid, water

PROCEDURE Mix 5 mL ethanoic acid (acetic acid) and 5 mL isoamyl alcohol in each of two test tubes. To one test tube, add a few granules of anhydrous calcium sulfate. Then add 3 drops of concentrated sulfuric acid to each test tube. Heat the test tubes in a boiling water bath for a few minutes. **Ask** Predict which reaction you think will yield the most product. *(Answers will vary.)* Then compare the results qualitatively by strength of odor or quantitatively if you have access to gas phase chromatography (GC) equipment.

EXPECTED OUTCOME

The tube containing anhydrous calcium sulfate yields the larger amount of product.

Factors Affecting Equilibrium: Le Châtelier's Principle

What three stresses can cause a change in the equilibrium position of a chemical system?

READING SUPPORT

Build Reading Skills: ***Cause and Effect*** As you read about Le Châtelier's principle, identify the effect that each type of stress (cause, in this case) has on the equilibrium position. ***How do changes in concentration affect the equilibrium position?***

The balance that exists in a chemical system at equilibrium is a delicate one. It can be disrupted when one or more of the conditions of the reaction are changed. When the equilibrium of a system is disturbed, the system makes adjustments to restore the equilibrium. However, the equilibrium position of the restored equilibrium will not be the same as the original equilibrium position. That is, the amount of reactants may have increased or the amount of products may have increased. Such a change is called a shift in the equilibrium position.

The French chemist Henri Le Châtelier (1850–1936) studied how the equilibrium position shifts as a result of changing conditions. He proposed what has come to be called **Le Châtelier's principle:** If a stress is applied to a system in dynamic equilibrium, the system changes in a way that relieves the stress. **Stresses that upset the equilibrium of a chemical system include changes in concentration of reactants or products, changes in temperature, and changes in pressure.**

In the examples of Le Châtelier's principle presented in this lesson, reactants will be to the left of the double arrow and products will be to the right. Blue arrows show the shifts when something is added to or removed from the system. The blue arrows always point in the direction of the shift in the equilibrium position—that is, toward the favored side.

Concentration Changing the amount, or concentration, of any reactant or product in a system at equilibrium disturbs the equilibrium. The system will adjust to minimize the effects of the change. Consider the decomposition of carbonic acid (H_2CO_3) in aqueous solution. The products are carbon dioxide and water. The system has reached equilibrium. The amount of carbonic acid is less than 1 percent.

$$H_2CO_3(aq) \underset{\text{Direction of shift} \rightarrow}{\overset{\text{Add } CO_2 \text{ or Direction of shift} \leftarrow}{\rightleftharpoons}} CO_2(aq) + H_2O(l)$$

$<1\%$ $>99\%$

Suppose carbon dioxide is added to the system. This increase in the concentration of CO_2 causes the rate of the reverse reaction to increase. As more reactant (H_2CO_3) is formed, the rate of the forward reaction also begins to increase. In time, the rates of the forward and reverse reactions again become equal. A new equilibrium is established with a higher concentration of reactant (H_2CO_3). Adding a product to a reaction at equilibrium pushes a reversible reaction in the direction of the reactants.

Suppose, on the other hand, carbon dioxide is removed. This decrease in the concentration of CO_2 causes the rate of the reverse reaction to decrease. As less reactant (H_2CO_3) is formed, the rate of the forward reaction also begins to decrease. In time, the rates of the forward and reverse reactions again become equal. The equilibrium is restored but at a different equilibrium position. Removing a product always pulls a reversible reaction in the direction of the products.

Professional Development Note

Environmental Issues

The ammonia produced by the Haber-Bosch process reacts with nitric acid to create ammonium nitrate, a product typical used as a fertilizer for crop growth. There are environmental disadvantages to using nitrogen fertilizer to generate a greater crop yield. Excess fertilizer can flow into streams and rivers after a large rainstorm and adversely affect various habitats due to the chain reaction caused by the contamination. The fertilizer causes a rapid increase in algae, which exceeds the ability of its consumers to control its population. The abundance of dead algae leads to an massive increase in the population of bacterial decomposers in the pond. The bacteria consume large quantities of dissolved oxygen, leading to the death of a large number of fish. Also, high levels of nitrates in drinking water have been associated with methemoglobinemia in humans. Methemoglobin is a form of hemoglobin that cannot bind oxygen.

Farmers use the removal of a product to increase the yield of eggs laid by hens. Hens lay eggs and then proceed to hatch them. If the eggs are removed after they are laid, the hen will lay more eggs. Similarly as products are removed from a reaction mixture, the system attempts to restore equilibrium by producing more products. However, the reaction can never reestablish equilibrium because the products are constantly being removed. The reaction continues to produce products until the reactants are used up.

Your body provides another example of the effect of removing a product. Carbon dioxide is a product of the reactions that provide your body with energy. Carbon dioxide produced in the cells is carried through blood vessels to the lungs. Some of the carbon dioxide diffuses from the blood into the lungs and is exhaled into the air. An equilibrium between carbonic acid, carbon dioxide, and water exists in your blood.

The athletes in Figure 18.15 use more energy than a person at rest. During exercise, the concentration of CO_2 in the blood increases. This increase in CO_2 shifts the equilibrium in the direction of carbonic acid. The level of H_2CO_3 in the blood needs to remain fairly constant. Fortunately, the increase in the level of CO_2 also triggers an increase in the rate of breathing. With more breaths per minute, more CO_2 is removed through the lungs. The removal of CO_2 causes the equilibrium to shift toward the products, which reduces the amount of H_2CO_3.

The same principle applies to adding or removing reactants. When a reactant is added to a system at equilibrium, the reaction shifts in the direction of the formation of products. When a reactant is removed, the reaction shifts in the direction of formation of reactants.

Figure 18.15 Effect of Concentration on Equilibrium Carbon dioxide is a product of reactions in cells. Rapid breathing during and after vigorous exercise helps reduce the level of CO_2 in the blood and, thus, helps control the level of H_2CO_3.
Predict ***Is the concentration of CO_2 greater in inhaled air or in exhaled air? Explain.***

Professional Development Note

Carbon Monoxide

Molecules such as carbon monoxide (CO) that are structurally similar to the oxygen molecule can bind to the hemoglobin molecule. Therefore, they compete with oxygen for the same binding locations. This competition is the cause of carbon monoxide poisoning. Because their affinity for the heme group is greater, carbon monoxide molecules can displace oxygen molecules from hemoglobin.

$$HbO_2 + CO \rightleftharpoons HbCO + O_2$$

The equilibrium in this reaction lies far to the right because the affinity of carbon monoxide for heme is approximately 150 times stronger than that of oxygen.

Explain

USE VISUALS Direct students' attention to the inset diagram in Figure 18.15. Discuss the effects of adding and removing carbon dioxide from the system. Point out that gaseous carbon dioxide in the lungs is in equilibrium with aqueous, or dissolved, carbon dioxide in the blood. Explain that the removal of carbon dioxide from the lungs by exhalation allows more carbon dioxide to diffuse from the blood into the lungs.

MAKE A CONNECTION Ask a volunteer to explain a time when he or she was exerting so much energy during an athletic contest that he or she could not catch his or her breath. **Ask** What changes do you feel happening in your body when you are exercising? *(Sample answers: faster breathing rate, faster heart rate, sweating)* Point out that during and after vigorous exercise, more CO_2 than usual needs to be removed to maintain the body's equilibrium. During exercise, the increased breathing rate also is needed to supply muscles with extra oxygen.

APPLY CONCEPTS Write the following equation on the board. $2H_2(g) + O_2(g) + \text{heat} \rightleftharpoons 2H_2O(g)$

Prior to showing students how stresses on a reaction affect the reaction, pair students and have them follow the Think-Pair-Share strategy to predict what happens with the reaction if:

- concentration of hydrogen increases *(The reaction will shift to the right to produce more product.)*
- concentration of hydrogen decreases *(The reaction will shift to the left.)*
- temperature is increased *(Reaction will shift to the right.)*
- pressure is increased *(The reaction will shift to the right.)*
- a catalyst is added *(The reaction will occur faster.)*

Continue teaching this section and have each pair of students revisit their predictions to clarify any misunderstandings.

Answers

READING SUPPORT An increase in concentration of a reactant or product will cause a shift in the equilibrium position in the reverse direction.

Explain

CHEMISTRY & YOU

USE VISUALS Direct students to Figure 18.16. **Ask** How does the equilibrium in cylinder a relate to the equilibrium in cylinder c? *(Increasing the pressure on the system in cylinder a caused the reaction to shift to the right, producing more molecules of product in cylinder c.)* **Ask** What state(s) of matter can a change in pressure affect? *(gas)*

MAKE A CONNECTION Point out that the industrial production of ammonia is an example of a practical application of Le Châtelier's principle. Write the equilibrium equation on the board. **Ask** Based on the equilibrium equation, select ideal temperature and pressure conditions for the highest possible yield of ammonia. *(high pressure and low temperature)* Tell students that the industrial process that was devised by Carl Bosch actually uses both high temperature and pressure plus an iron-based catalyst. **Ask** Why doesn't Bosch's process use the conditions predicted by Le Châtelier's principle? *(A higher-than-ideal temperature—plus the catalyst—is needed to increase the reaction rate.)* Explain that an efficient industrial process must often strike a balance between multiple goals, in this case, the need for high yield and fast reaction time.

Sample Practice Problem

The gases dinitrogen tetroxide and nitrogen dioxide exist in equilibrium according to the equation

$$N_2O_4(g) + 58\ kJ \rightleftharpoons 2NO_2(g)$$

What effect do the following changes have on the equilibrium position?

a. addition of heat *(favors products)*
b. decrease in pressure *(favors products)*
c. addition of NO_2 *(favors reactants)*
d. removal of N_2O_4 *(favors reactants)*

CHEMISTRY & YOU

Q: *Fritz Haber and Karl Bosch figured out how to increase the yield of ammonia when nitrogen and hydrogen react. Their success came from controlling the temperature and pressure. In which direction did they adjust each factor, and why?*

Temperature Increasing the temperature causes the equilibrium position of a reaction to shift in the direction that absorbs heat. In other words, it will shift in the direction that reduces the stress. For example, the reaction that occurs when ammonia (NH_3) is produced from N_2 and H_2 is exothermic.

$$N_2(g) + 3H_2(g) \underset{\text{Direction of shift}\rightarrow}{\overset{\text{Add heat.}\ \leftarrow\text{Direction of shift}}{\rightleftharpoons}} 2NH_3(g) + \text{heat}$$

Heat can be considered to be a product, just like NH_3. Heating the reaction mixture at equilibrium pushes the equilibrium position to the left, which favors the reactants. As a result, the product yield decreases. Cooling, or removing heat, pulls the equilibrium position to the right, and the product yield increases.

Pressure Equilibrium systems in which some reactants and products are gases can be affected by a change in pressure. A shift will occur only if there are an unequal number of moles of gas on each side of the equation. The reaction in which ammonia forms is a useful example. Figure 18.16 shows how a change in pressure affects the system. The three gases are in a cylinder with a piston attached to a plunger. When the plunger is pushed down, the volume decreases and the pressure increases. You can predict which way the equilibrium position will shift by comparing the number of molecules of reactants and products. When two molecules of ammonia form, four molecules of reactants are used up (three of hydrogen and one of nitrogen). A shift toward ammonia (the product) will reduce the number of molecules. This shift will decrease the pressure but not to the original pressure.

$$N_2(g) + 3H_2(g) \underset{\text{Reduce pressure.}\ \leftarrow\text{Direction of shift}}{\overset{\text{Increase pressure.}\ \text{Direction of shift}\rightarrow}{\rightleftharpoons}} 2NH_3(g)$$

A change in pressure can be used to favor the reactants in the ammonia reaction. Pulling up on the plunger in Figure 18.16 will increase the volume that the gases occupy. This increase in volume causes a decrease in pressure. Adding molecules to the container can help to restore the pressure. Thus, the decomposition of ammonia, which increases the number of molecules, is favored. A new equilibrium is established at a pressure that is higher than when the system was disturbed but not as high as the original pressure.

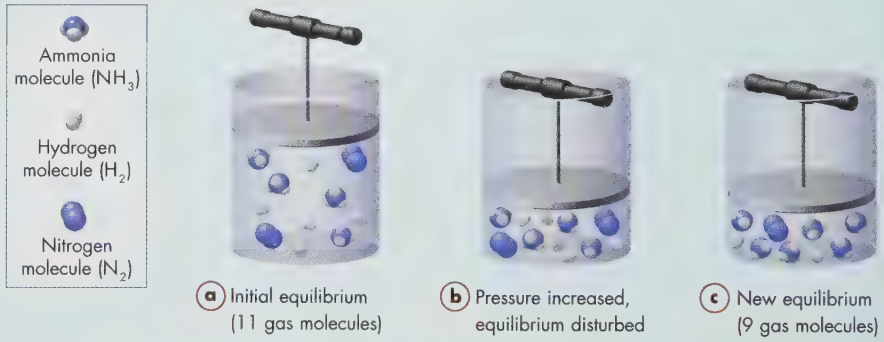

Figure 18.16
Effect of Pressure on Equilibrium
Pressure affects a mixture of nitrogen, hydrogen, and ammonia. **a.** The system is at equilibrium. **b.** Equilibrium is disturbed by an increase in pressure. **c.** A new equilibrium position is established with fewer molecules.
Explain ***How does the ideal gas law (PV = nRT) explain this shift in the equilibrium position?***

UbD

Check for Understanding

What three stresses can cause a change in the equilibrium position of a chemical system?

Ask students to indicate with a thumbs-up or thumbs-down whether they understand that changes in temperature, concentration, or pressure are stresses that can affect or disturb a chemical reaction at equilibrium.

ADJUST INSTRUCTION If students are having difficulty answering the question, have them review the Conditions at Equilibrium section as well as the discussion on Le Châtelier's principle to clarify their understanding.

Catalysts and Equilibrium Catalysts decrease the time it takes to establish equilibrium. However, they do not affect the amounts of reactants and products present at equilibrium. The energy path for a reverse reaction is the exact opposite of the energy path for the forward reaction. So adding a catalyst lowers the energy path by the same amount for both reactions.

Sample Problem 18.2

Applying Le Châtelier's Principle

What effect will each of the following changes have on the equilibrium position for this reversible reaction?

$$PCl_5(g) + \text{heat} \rightleftharpoons PCl_3(g) + Cl_2(g)$$

a. Cl_2 is added.
b. Pressure is increased.
c. Heat is removed.
d. PCl_3 is removed as it forms.

1 Analyze **Identify the relevant concepts.** According to Le Châtelier's principle, the equilibrium position will shift in a direction that minimizes the imposed stress.

2 Solve **Apply the concepts to this problem.**

Start with the addition of Cl_2.

a. Cl_2 is a product. Increasing the concentration of a product shifts the equilibrium to the left.

Analyze the effect of an increase in pressure.

b. Reducing the number of gas molecules decreases the pressure. The equilibrium shifts to the left.

Analyze the effect of removing heat.

c. The reverse reaction produces heat. The removal of heat causes the equilibrium to shift to the left.

Analyze the effect of removing PCl_3.

d. PCl_3 is a product. Removal of a product as it forms causes the equilibrium to shift to the right.

17. How is the equilibrium position of this reaction affected by the following changes?

$$2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g) + \text{heat}$$

a. lowering the temperature
b. decreasing the pressure
c. removing oxygen
d. adding sulfur trioxide (SO_3)

18. How is the equilibrium position of this reaction affected by the following changes?

$$C(s) + H_2O(g) + \text{heat} \rightleftharpoons CO(g) + H_2(g)$$

a. lowering the temperature
b. increasing the pressure
c. removing hydrogen
d. adding water vapor

For a change in pressure, compare the number of gas molecules on both sides of the equation.

Differentiated Instruction

L1 LESS PROFICIENT READERS Allow students to visually discover the effect of decreasing pressure on a substance by showing them how and why a carbonated beverage goes flat.

L1 SPECIAL NEEDS Engage students in **Sample Problem 18.2** by having them stand up and spread their arms wide. Tell students that their arms represent the dual arrows indicating the reversible reaction. Have students lean one way or the other to indicate how the reaction is affected by each stress.

L3 ADVANCED STUDENTS Have students find an online applet that simulates Le Châtelier's principle. Have students create a graphical representation of what they discovered.

Explore

Factors Affecting Equilibrium: Le Châtelier's Principle

Teacher Demo

PURPOSE Students observe the effect of temperature changes on the equilibrium position of an exothermic reaction.

MATERIALS 3 g copper turnings, 3 heat-resistant test tubes, 10 mL 6*M* nitric acid, one-hole stopper, 2 solid stoppers, glass delivery tube, rubber tubing, warm water bath, ice water bath

PROCEDURE Place a small amount (3 g or less) of copper turnings in a test tube, and add 10 mL of 6*M* nitric acid (HNO_3). Insert a one-hole stopper, fitted with a glass delivery tube and rubber tubing, into the test tube. Fill two test tubes with the brown gas that forms. When the color is the same as in the reacting test tube, stopper the tubes. Once sealed, the tubes can be saved indefinitely for repeated use, or discharged in a fume hood.

SAFETY Use a fume hood. Nitric acid is corrosive, and NO_2 is a toxic gas.

PROCEDURE Set up an ice bath and a warm water bath (70–80°C). Hold up the tubes for students to see and tell them that each tube contains NO_2 gas. Place one tube in warm water and the other in cold water. After a few minutes, remove the tubes and have students compare their colors. Now reverse the positions of the tubes in the water baths and after a few minutes, have students again observe the colors.

Write the reaction equation on the board:

$$2NO_2(g) \rightleftharpoons N_2O_4(g) + \text{heat}$$

Explain that nitrogen dioxide is brown and dinitrogen tetroxide is colorless. Ask students to explain the effect of changing temperature. *(Adding heat shifts the equilibrium in the direction that absorbs heat, to the left. Removing heat shifts the equilibrium in the direction that produces heat, to the right.)*

Answers

FIGURE 18.16 Increasing the pressure causes a decrease in volume, which shifts the equilibrium in the direction of fewer gas molecules.

d. favors products

Explain

Equilibrium Constants

START A CONVERSATION Remind students of the specific reaction rate constant they learned in Lesson 18.1 and the way in which they learned to determine the order of a reaction. Then explain that the fixed numerical relationship between the reactants and products of a chemical system at equilibrium is called the equilibrium constant, typically symbolized by K_{eq}. **Ask** Based on what you have learned about equilibrium so far, what predictions do you think you can make given the value of an equilibrium constant of a reaction? *(the equilibrium shift of the reaction)*

INTERPRET A DIAGRAM Direct students to Figure 18.17. Tell students to count the number of circles and the number of squares in each flask. **Ask** What did you notice about the numbers of circles and squares in each flask? *(The number of circles in the warm flask is equal to the number of squares in the cool flask; and vice versa.)* Explain that this diagram represents a system at equilibrium. Point out that whenever a chemical system reaches equilibrium, the reactants and products have a fixed numerical relationship. Once students show understanding, guide them to Sample Problem 18.3, in which they can calculate the constant for the reaction represented by this diagram.

Extend

Have students write equilibrium expression for the production of ammonia from nitrogen and hydrogen.

$$K_{eq} = \frac{[NH_3]^2}{[N_2][H_2]^3}$$

Equilibrium Constants

What does the size of an equilibrium constant indicate about a system at equilibrium?

Chemists express the equilibrium position as a numerical value. This value relates the amounts of reactants to products at equilibrium. Look at the following general reaction in which two reactants form two products. The coefficients *a*, *b*, *c*, and *d* represent the number of moles.

$$aA + bB \rightleftharpoons cC + dD$$

The **equilibrium constant** (K_{eq}) is the ratio of product concentrations to reactant concentrations at equilibrium. Each concentration is raised to a power equal to the number of moles of that substance in the balanced chemical equation. Here is the expression for the equilibrium constant for the general reaction stated above.

$$K_{eq} = \frac{[C]^c \times [D]^d}{[A]^a \times [B]^b}$$

The exponents in the equilibrium-constant expression are the coefficients in the balanced chemical equation. The concentrations of substances are in moles per liter (mol/L). The value of K_{eq} depends on the temperature of the reaction. If the temperature changes, the value of K_{eq} also changes.

The size of the equilibrium constant indicates whether reactants or products are more common at equilibrium. When K_{eq} has a large value, such as 3.1 to 10^{11}, the reaction mixture at equilibrium will consist mainly of product. When K_{eq} has a small value, such as 3.1 to 10^{-11}, the mixture at equilibrium will consist mainly of reactant. When K_{eq} has an intermediate value, such as 0.15 or 50, the mixture will have significant amounts of both reactant and product.

When the value of an equilibrium constant is calculated, the cancellation of units may or may not lead to a unit for the constant. As a result, chemists have agreed to report equilibrium constants without a stated unit. Sample Problem 18.3 shows how to calculate the equilibrium constant for the reaction illustrated in Figure 18.17.

Figure 18.17
Favoring Reactants or Products
Dinitrogen tetroxide is a colorless gas. Nitrogen dioxide is a brown gas. The flask on the left is in a dish of hot water. The flask on the right is in ice.
Interpret Diagrams ***How does an increase in temperature affect the equilibrium mixture of these gases?***

UbD Check for Understanding

What does the size of an equilibrium constant indicate about a system at equilibrium?

Assess students' understanding about an equilibrium system by asking them to explain mathematically how an equilibrium constant can be used to make a prediction about the general concentration of reactants and products at equilibrium.

(Sample answer: K_{eq} = [products]/[reactants]; If you divide a small number by a large number, the quotient is a very small number. So, if K_{eq} is a small value, then the concentration of reactants has to be much smaller than the concentration of products, and vice versa.)

ADJUST INSTRUCTION If students are having trouble answering, show them a simplified version of a ratio representing the equilibrium constant. Have students use large and small and similar values for the concentrations and calculate the constant. Tell students to look for a pattern they can use to make predictions.

Sample Problem 18.3

Expressing and Calculating K_{eq}

The colorless gas dinitrogen tetroxide (N_2O_4) and the brown gas nitrogen dioxide (NO_2) exist in equilibrium with each other.

$$N_2O_4(g) \rightleftharpoons 2NO_2(g)$$

A liter of the gas mixture at equilibrium contains 0.0045 mol of N_2O_4 and 0.030 mol of NO_2 at 10°C. Write the expression for the equilibrium constant (K_{eq}) and calculate the value of the constant for the reaction.

1 Analyze **List the knowns and the unknowns.**
Modify the general expression for the equilibrium constant and substitute the known concentrations to calculate K_{eq}.

KNOWNS	UNKNOWNS
$[N_2O_4] = 0.0045$ mol/L	K_{eq} (algebraic expression) = ?
$[NO_2] = 0.030$ mol/L	K_{eq} (numerical value) = ?

2 Calculate **Solve for the unknowns.**

Start with the general expression for the equilibrium constant.

$$K_{eq} = \frac{[C]^c \times [D]^d}{[A]^a \times [B]^b}$$

Place the concentration of the product in the numerator and the concentration of the reactant in the denominator. Raise each concentration to the power equal to its coefficient in the chemical equation

Write the equilibrium constant expression for this reaction.

$$K_{eq} = \frac{[NO_2]^2}{[N_2O_4]}$$

Substitute the concentrations that are known, and calculate K_{eq}.

$$K_{eq} = \frac{(0.030 \text{ mol/L})^2}{0.0045 \text{ mol/L}} = \frac{(0.030 \text{ mol/L} \times 0.030 \text{ mol/L})}{0.0045 \text{ mol/L}}$$

$$= 0.20 \text{ mol/L} = 0.20$$

You can ignore the unit mol/L; chemists report equilibrium constants without a stated unit.

3 Evaluate **Does the result make sense?** Each concentration is raised to the correct power. The numerical value of the constant is correctly expressed to two significant figures. The value for the K_{eq} is appropriate for an equilibrium mixture that contains significant amounts of both gases.

Here's a hint for Problem 20: Calculate $1/K_{eq}$ for the forward reaction.

19. The reaction in which ammonia is formed is $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$. At equilibrium, a 1-L flask contains 0.15 mol H_2, 0.25 mol N_2, and 0.10 mol NH_3. Calculate K_{eq} for this reaction.

20. Using the equilibrium conditions described in Problem 19, Calculate K_{eq} for $2NH_3(g) \rightleftharpoons N_2(g) + 3H_2(g)$. How is the K_{eq} for a forward reaction related to the K_{eq} for a reverse reaction?

Foundations for Math

WORKING WITH EXPONENTS Remind students to apply the properties of powers when simplifying quantities and units. In **Sample Problem 18.3,** the Power of Product rule, $(a^x)^y = a^{xy}$, and the Power of a Quotient rule, $\frac{a^x}{a^y} = a^{x-y}$, when $a \neq 0$ can be used to simplify Step 2.

Remind students that anything inside a set of parentheses that is raised to a given power is affected by the exponent, including units of measurements. This is demonstrated in the third equation of step 2 above, where $(0.030 \text{ mol/L})^2$ is rewritten as (0.030 mol/L) × (0.030 mol/L), rather than (0.030 × 0.030) mol/L.

Explain

APPLY CONCEPTS Show students how to set up and solve problems involving equilibrium constants. Stress the following:

- the only quantities that are used to determine the value of the equilibrium constant expression are concentrations, or quantities which are related to concentrations, like partial pressures
- the units for concentration are often given as moles per liter
- an equilibrium constant does not have units; it is a unitless constant
- be sure to subtract the number of moles that react from the number of moles originally present in order to determine the number remaining at equilibrium.

CRITICAL THINKING Have students examine the similarities and differences in the expressions used to determine an equilibrium constant with the way to determine the specific reaction rate constant in Lesson 18.

Sample Practice Problem

Analysis of an equilibrium mixture of hydrogen, iodine, and hydrogen iodide contained in a 10.0-L flask at a certain temperature gives the following results: hydrogen, 0.15 mol; iodine, 0.15 mol; hydrogen iodide, 0.87 mol. Calculate K_{eq} for the reaction:

$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$$

($K_{eq} = 34$)

Answers

FIGURE 18.17 An increase in temperature causes the equilibrium to shift toward the formation of more NO_2.

19. $K_{eq} = 12$

20. $K_{eq} = 8.4 \times 10^{-2}$; One is the inverse of the other.

Explain

CRITICAL THINKING Students often think they need to use all of the information provided in a problem statement. Help students to understand that some of the values that are given in an equilibrium problem involve the conditions of the reaction. When determining the equilibrium constant, these values are not needed in the calculation. Students may, however, be able to draw conclusions about the factors that are driving the equilibrium in one direction or another. Ask students to infer which of the three factors that affect an equilibrium is providing stress to the system in Sample Problem 18.4. *(high temperature)*

Sample Practice Problems

A. Write the equilibrium constant for the following reaction.

$$H_2(g) + Br_2(g) \rightleftharpoons 2HBr(g)$$

$$\left(K_{eq} = \frac{[HBr]^2}{[H_2][Br_2]} \right)$$

B. Determine the value of K_{eq} for the reaction in problem A for the following concentrations at equilibrium in a 2-L container: 0.7 mol of H_2, 0.5 mol of Br_2, and 0.8 mol of HBr.

(K_{eq} = 1.8)

Sample Problem 18.4

Finding the Equilibrium Constant

One mole of colorless hydrogen gas and one mole of violet iodine vapor are sealed in a 1-L flask and allowed to react at 450°C. At equilibrium, 1.56 mol of colorless hydrogen iodide is present, together with some of the reactant gases. Calculate K_{eq} for the reaction.

$$H_2(g) + I_2(g) \rightleftharpoons 2HI(g)$$

1 Analyze **List the knowns and the unknowns.** Find the concentrations of the reactants at equilibrium. Then substitute the equilibrium concentrations in the expression for the equilibrium constant for this reaction.

KNOWNS	UNKNOWN
$[H_2]$ (initial) = 1.00 mol/L	K_{eq} = ?
$[I_2]$ (initial) = 1.00 mol/L	
[HI] (equilibrium) = 1.56 mol/L	

2 Calculate **Solve for the unknown.**

First use the balanced equation to find out how much H_2 and I_2 are consumed in the reaction.

$$1.56 \text{ mol HI} \times \frac{1 \text{ mol } H_2}{2 \text{ mol HI}} = 0.780 \text{ mol } H_2$$

In this reaction, the number of mol I_2 used equals mol H_2 used.

Calculate how much H_2 and I_2 remain at equilibrium.

$$\text{mol } H_2 = \text{mol } I_2 = (1.00 \text{ mol} - 0.780 \text{ mol}) = 0.22 \text{ mol}$$

Write the expression for K_{eq}.

$$K_{eq} = \frac{[HI]^2}{[H_2] \times [I_2]}$$

Use the general expression for K_{eq} as a guide:

$$K_{eq} = \frac{[C]^c \times [D]^d}{[A]^a \times [B]^b}$$

Substitute the equilibrium concentrations of the reactants and products into the equation and solve for K_{eq}.

$$K_{eq} = \frac{(1.56 \text{mol/L})^2}{0.22 \text{ mol/L} \times 0.22 \text{ mol/L}} = \frac{1.56 \text{ mol/L} \times 1.56 \text{ mol/L}}{0.22 \text{ mol/L} \times 0.22 \text{ mol/L}} = 5.0 \times 10^1$$

3 Evaluate **Does the result make sense?** Each concentration is raised to the correct power. The value of the constant reflects the presence of significant amounts of reactants and product in the equilibrium mixture.

In Problem 22, you must first find the equilibrium concentrations of H_2 and CO_2.

21. Suppose the following system reaches equilibrium:
$N_2(g) + O_2(g) \rightleftharpoons 2NO(g)$
Analysis of the equilibrium mixture in a 1-L flask gives the following results: 0.50 mol of N_2, 0.50 mol of O_2, and 0.020 mol of NO. Calculate K_{eq} for the reaction.

22. At 750°C, the following reaction reaches equilibrium in a 1-L flask:
$H_2(g) + CO_2(g) \rightleftharpoons H_2O(g) + CO(g)$
The reaction begins with 0.10 mol H_2 and 0.10 mol CO_2. At equilibrium, there is 0.047 mol H_2O and 0.047 mol CO. Calculate K_{eq} for the reaction.

Foundations for Math

COMBINING LIKE TERMS Remind students that the first step in solving multi-step equations often involves combining like terms. Explain that to add and subtract terms in an expression, they must have the same variable raised to the same power.

In Sample Problem 18.4, since the moles of each reactant are equal, x can be used to represent the number of moles of H_2 used as well as the number of moles of I_2 used. Thus, the total moles of reactants used is $x + x$, or $1x + 1x$. Point out that the coefficient and the exponent are both understood to be 1. Since the base of each term in the expression is the same, x, and the exponent is the same, 1, then to combine the terms, you add coefficients and keep the exponent the same. So, $1x + 1x = 2x$.

Sample Problem 18.5

Finding Concentrations at Equilibrium

Bromine chloride (BrCl) decomposes to form bromine and chlorine.

$$2BrCl(g) \rightleftharpoons Br_2(g) + Cl_2(g)$$

At a certain temperature, the equilibrium constant for the reaction is 11.1. A sample of pure BrCl is placed in a 1-L container and allowed to decompose. At equilibrium, the reaction mixture contains 4.00 mol Cl_2. What are the equilibrium concentrations of Br_2 and BrCl?

1 Analyze **List the knowns and the unknowns.**
Use the balanced equation, equilibrium constant, and the equilibrium constant expression to find the unknown concentrations. According to the balanced equation, when BrCl decomposes, equal numbers of moles of Br_2 and Cl_2 are formed.

KNOWNS	UNKNOWNS
$[Cl_2]$ (equilibrium) = 4.00 mol/L	$[Br_2]$ (equilibrium) = ? mol/L
K_{eq} = 11.1	[BrCl] (equilibrium) = ? mol/L

2 Calculate **Solve for the unknowns.**

The volume of the container is 1 L, so calculate $[Br_2]$ at equilibrium.

$$[Br_2] = \frac{4.00\ mol}{1\ L} = 4.00\ mol/L$$

Write the equilibrium expression for the reaction.

$$K_{eq} = \frac{[Br_2] \times [Cl_2]}{[BrCl]^2}$$

Rearrange the equation to solve for [BrCl]. Then substitute the known values for K_{eq}, $[Br_2]$, and $[Cl_2]$.

$$[BrCl]^2 = \frac{[Br_2] \times [Cl_2]}{K_{eq}} = \frac{4.00\ mol/L \times 4.00\ mol/L}{11.1}$$

$$= 1.44\ mol^2/L^2$$

Find [BrCl] by taking the square root of each side of the equation.

$$[BrCl] = \sqrt{1.44\ mol^2/L^2} = 1.20\ mol/L$$

Use your calculator to find the square root.

3 Evaluate **Does the result make sense?** It makes sense that the equilibrium concentration of the reactant and the products are both present in significant amounts because K_{eq} has an intermediate value.

23. At a certain temperature, the equilibrium constant for the reaction in which nitrogen dioxide forms dinitrogen tetroxide is 5.6.

$$2NO_2(g) \rightleftharpoons N_2O_4(g)$$

In a 1-L container, the amount of N_2O_4 at equilibrium is 0.66 mol. What is the equilibrium concentration of NO_2?

24. Hydrogen iodide decomposes to form hydrogen and iodine.

$$2HI(g) \rightleftharpoons H_2(g) + I_2(g)$$

In a 1-L container at 450°C, the equilibrium mixture contains 0.50 mol of hydrogen. What are the equilibrium concentrations of hydrogen and hydrogen iodide? (K_{eq} = 0.020)

Foundations for Math

SOLVING EQUATIONS WITH SQUARE ROOTS Remind students that when solving an equation involving a variable with an exponent, such as x^2, students should isolate this variable term and then take the square root of both sides in order to find the value for x. Point out that $x^2 = a$, so $x = \sqrt{a}$

In **Sample Problem 18.5**, let x = [BrCl] and show students that $[BrCl]^2 = 1.44\ mol^2/L^2$ can be represented algebraically as $x^2 = 1.44\ mol^2/L^2$.

$$x^2 = 1.44\ mol^2/L^2$$

$$\sqrt{x^2} = \sqrt{1.44\ mol^2\ L^2}$$

$$\sqrt{x^2} = \sqrt{1.44} \cdot \sqrt{\frac{mol^2}{L^2}}$$

$$x^2 = 1.20\ mol/L$$

Explain

APPLY CONCEPTS Point out that a reversible reaction can be written in either order, reactants followed by product, or products followed by reactants. **Ask** Does a reversible reaction have the same equilibrium constant regardless of the way it is written? Why? *(No; the reverse reaction is the reciprocal of the equilibrium constant of the forward reactions.)*

MAKING CONNECTIONS Relate the procedure for finding the unknown in Sample Problem 18.5 to solving a multi-step equation in algebra. Have students identify the key words to use in order to correctly set up the problem.

Sample Practice Problem

At elevated temperatures, molecular hydrogen and molecular bromine react to form hydrogen bromide:

$$H_2(g) + Br_2(g) \rightleftharpoons 2HBr(g)$$

A mixture of 0.77 mol of H_2 and 0.57 mol of Br_2 is combined in a 1-L vessel. At equilibrium, at a high temperature, there are 0.49 mol of Br_2 present. How many moles of H_2 are there at equilibrium? *(0.69 mol)*

Answers

21. $K_{eq} = 1.6 \times 10^{-3}$
22 $K_{eq} = 0.79$
23. $[NO_2] = 0.34M$
24. [H2] = [I2] = 0.50M; [HI] = 3.5M

CHEMISTRY & YOU

CHEMISTRY & YOU Chemical reaction kinetics, coupled with courses in materials of science and thermodynamics, equip chemical engineers with the necessary tools to design, prove, create, and discover behaviors of substances found in sundry disciplines. Although the coursework to become a chemical engineer is heavy in chemistry courses, chemical engineers are also required to have a strong understand of physics and higher-level mathematics in order to understand how the three disciplines are related.

Extend

Ask students to research and find the properties of wax that allows for it to be a useful product for surfers. Have students generate a list of parameters that were likely involved in determining the type of substance needed for this surfing application.

Evaluate

Informal Assessment

Write several reversible chemical equations on the board. Have students use Le Châtelier's principle to predict how they could increase the yield of a reaction product.

Then write the general reversible chemical reaction shown below on the board.

$$aA + bB \rightleftharpoons cC + dD$$

Ask students write the equation for calculating the equilibrium constant for this reaction.

$$K_{eq} = \left[\frac{[C]^c[D]^d}{[A]^a[B]^b}\right]$$

Reteach

If students have trouble understanding Le Châtelier's principle and the equilibrium constant, list the steps for writing the correct equilibrium constant expression from a balanced equation. Then guide them through Sample Problems 18.2–18.5 again. Encourage students to summarize their understanding of each concept in a bulleted list.

CHEMISTRY & YOU: CAREERS

Chemical Engineer

You may think that surfing is about as far away from chemistry as you can get. But you'd be wrong! Surfboards, wet suits, and even the synthetic waxes used to help keep your feet on the board were created using products developed by chemical engineers.

Chemical engineers are primarily concerned with the large-scale manufacture of chemical products, such as plastics and other petroleum products, pharmaceuticals, and foods. Chemical engineers may also be involved in research, the design and development of processing plants, the evaluation of operating processes, and the extraction and processing of raw materials.

Take It Further

1. Infer What are some reasons why chemical engineers might need a wide range of science and engineering knowledge in their work?

2. Identify What are some products you use every day that could have been developed by a chemical engineer?

18.3 LessonCheck

25. Review What happens to the amounts of reactants and products after a reaction has reached chemical equilibrium?

26. List What are the three stresses that can upset the equilibrium of a chemical system?

27. Explain What does the value of the equilibrium constant tell you about the amounts of reactants and products present at equilibrium?

28. Relate Cause and Effect Can a change in pressure shift the equilibrium position in every reversible reaction? Explain.

29. Describe How can you use a balanced chemical equation to write an equilibrium-constant expression?

30. Apply Concepts Which of the equilibrium constants indicates a reaction in which the amount of product is much larger than the amount of reactant at equilibrium? Explain.

a. $K_{eq} = 1 \times 10^{8}$

b. $K_{eq} = 3 \times 10^{-6}$

31. Calculate The equilibrium mixture for the reaction $2HI(g) \rightleftharpoons H_2(g) + I_2(g)$ contains 0.050 mol H_2. How many moles of I_2 and HI are present at equilibrium ($K_{eq} = 0.018$)?

BIG IDEA REACTIONS

32. Review the concept of percent yield from Lesson 12.3. How can understanding Le Châtelier's principle help chemists increase the percent yield of a reversible chemical reaction?

Lesson Check Answers

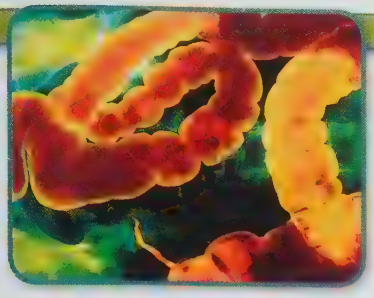
25. There is not a net change in the amounts of reactants or products.

26. changes in concentrations of reactants and products, changes in temperature, and changes in pressure

27. For a large K_{eq}, products dominate the reaction mixture; For a small K_{eq}, reactants dominate the reaction mixture.

28. no; only in reversible reactions in which the mole ratios of gaseous reactants and products are unequal

29. An equilibrium constant expression is a ratio. In the numerator, product concentrations are multiplied. In the denominator, reactant concentrations are multiplied. Each concentration is raised to a power equal to the coefficient for that species in the balanced equation.



30. a; At large K_{eq} values, products dominate the reaction mixture at equilibrium.

31. 0.050 mol I_2 and 0.37 mol HI

32. BIG IDEA They will know how to manipulate concentrations, temperature, and pressure to increase the percent yield of the reaction.

18.4 Solubility Equilibrium

C.7.2 Factors affecting solubility

CHEMISTRY & YOU

Q: *How is it possible to ingest a poison without being harmed?*
Chemical substances are needed to make organs other than bones visible on X-ray images. In one test, a patient drinks a thick liquid mixture that contains barium sulfate, which is a poison. Because barium sulfate can absorb X-rays, tissues coated with the liquid will appear as light areas in the X-ray images. This lesson will help you understand how a poison like barium sulfate can be safely used for this test.

Key Questions

What is the relationship between the solubility product constant and the solubility of a compound?

How can you predict whether precipitation will occur when two solutions are mixed?

Vocabulary

- solubility product constant
- common ion
- common ion effect

The Solubility Product Constant

What is the relationship between the solubility product constant and the solubility of a compound?

Most ionic compounds containing alkali metals are soluble in water. For example, more than 35 g of sodium chloride will dissolve in only 100 g of water. By contrast, some ionic compounds are insoluble in water. For example, compounds that contain phosphate, sulfite, or carbonate ions tend not to dissolve in water. Exceptions to this rule are compounds in which these ions are combined with ammonium ions or alkali metal ions. Table 18.1 provides some general rules for the solubility of ionic compounds in water.

Table 18.1

Solubility of Ionic Compounds in Water

Compounds	Solubility	Exceptions
Salts of Group 1A metals and ammonia	Soluble	Some lithium compounds
Ethanoates, nitrates, chlorates, and perchlorates	Soluble	Few exceptions
Sulfates	Soluble	Compounds of Pb, Ag, Hg, Ba, Sr, and Ca
Chlorides, bromides, and iodides	Soluble	Compounds of Ag and some compounds of Hg and Pb
Sulfides and hydroxides	Most are insoluble	Alkali metal sulfides and hydroxides are soluble. Compounds of Ba, Sr, and Ca are slightly soluble.
Carbonates, phosphates, and sulfites	Insoluble	Compounds of the alkali metals and of ammonium ions

Focus on ELL

1 CONTENT AND LANGUAGE Present the key questions slowly, then paraphrase the questions or use visual aids to help explain the intent of each question. Write word pairs such as *precipitation* and *precipitates*, *dissociated* and *associate*, and *common* and *uncommon* on the word wall. As a class, discuss the meaning of these words in a chemistry course.

2 FRONTLOAD THE LESSON Have students establish a purpose for reading. Students should create a list of three to four active questions they can answer as they read the text, the sample problems, and the tables.

3 COMPREHENSIBLE INPUT Introduce the concept of limited solubility by demonstrating the solubilities of equal amounts of sodium chloride and silver chloride in equal volumes of water. During the discussion of common ion effect, perform the teacher demonstration with silver chloride and silver nitrate.

LESSON 18.4

Key Objectives

DESCRIBE the relationship between the solubility product constant and the solubility of a compound.

PREDICT whether a precipitation will occur when two solutions are mixed.

Additional Resources

- Reading and Study Workbook, Lesson 18.4
- Probeware Laboratory Manual
- Virtual Chemistry Labs

Engage

CHEMISTRY & YOU Direct students to the photograph and the question at the lesson opener. **Ask** Why is $BaSO_4$ ingested by a patient before having an X-ray taken of the stomach? *(Soft tissues don't show up well in X-rays.)* **Ask** Why is the digestive system well suited to this type of image enhancement? *(Chemicals are easily brought into the system and easily removed.)*

Access Prior Knowledge

Ask students to identify the types of reactants and products studied in Lesson 18.3. *(Both reactants and products were gases.)* Explain that in this lesson, students will continue to learn about equilibrium; however, the reactants and particles will be liquids and solids. Ask students to draw on their prior knowledge to predict the form of the equilibrium constant expression for the dissolving of an ionic compound in water.

IN ACADEMIC STANDARDS for SCIENCE

C.7.2 Explain how temperature, pressure and polarity of the solvent affect the solubility of a solute.

Take It Further

1. Sample answers: to know how the manufacturing process affects the environment (environmental science); to know how to design a properly functioning reactor (physics, math, engineering)
2. Answers will vary.

Foundations for Reading

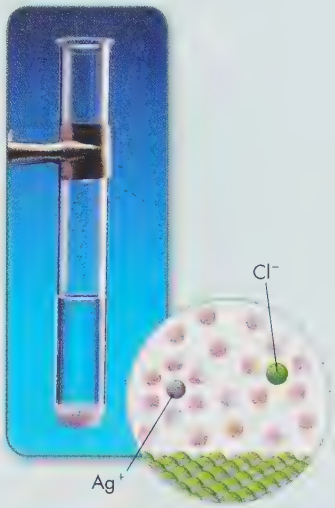
BUILD VOCABULARY Make sure students understand the difference between the terms *solubility* and *solubility product*. Have them write the definitions in their own words.

READING STRATEGY After reading this lesson, ask students to summarize what they learned about solubility constants and the common ion effect. Suggest that they use an equation to illustrate their summary.

Explain

The Solubility Product Constant

START A CONVERSATION Explain that any ionic solid placed in water establishes an equilibrium between its dissociated ions in solution and the solid that is undissolved. **Ask** Do you think all solids dissolve entirely in water, partially in water, or are insoluble in water? *(Answers will vary.)* As a class, brainstorm examples of solids that always dissolve in water, never dissolve in water, or partially dissolve in water. Explain that the solubility product constant is an equilibrium constant that describes the equilibrium between a solid and its ions in solution.



USE MODELS Explain that the solubility product constant is closely related to the equilibrium constant that students learned about in Lesson 18.2. Write the equilibrium equation on the board and compare it to the solubility product equation. Point out similarities in the equations for these two quantities. Write the sample problems on the board and carry out the solutions for the solubility product, K_{sp}. Focus on how to set up the algebraic expression.

USE VISUALS Have students examine Table 18.2. Call out a few of the compounds in Table 18.2 and have students identify the solubility product constant for each compound. Explain that chemists often utilize data tables such as this to look up critical information about a specific chemical. Be sure to explain that students will not have to memorize the information in a table such as Table 18.2 but that they will be expected to extract the necessary information from the table in order to answer a question.

Misconception Alert

Students often forget to balance a chemical equation prior to determining the solubility product constant. Make sure students understand that the chemical equation should be written with the solid as the reactant and the ion as the product.

Figure 18.18 Silver Chloride
Some ionic compounds, such as silver chloride, are slightly soluble in water.
Predict *Would adding solid silver chloride to this test tube increase the concentrations of silver ions and chloride ions?*

Most insoluble ionic compounds will actually dissolve to some extent in water. These compounds are said to be slightly soluble in water. Figure 18.18 models what happens when the "insoluble" compound silver chloride is mixed with water. A very small amount of silver chloride dissolves in the water. An equilibrium is established between the solid and the dissolved ions in the saturated solution.

$$AgCl(s) \rightleftharpoons Ag^+(aq) + Cl^-(aq)$$

You can write an equilibrium-constant expression for this process.

$$K_{eq} = \frac{[Ag^+] \times [Cl^-]}{[AgCl]}$$

The expression includes the dissolved ions, which are in solution, and the solid AgCl, which is not. To compare the solubility of salts, it is useful to have a constant that reflects only the concentrations of the dissolved ions. This constant is called the **solubility product constant** (K_{sp}), which is equal to the product of the concentrations of the ions each raised to a power equal to the coefficient of the ion in the dissociation equation.

$$K_{sp} = [A]^a \times [B]^b$$

The coefficients for the dissociation of silver chloride are each 1, so the K_{sp} expression for the dissociation is written as follows:

$$K_{sp} = [Ag^+] \times [Cl^-]$$

What does the size of the solubility product constant tell you about the solubility of a compound? **The smaller the value of the solubility product constant, the lower the solubility of the compound.** Table 18.2 lists the K_{sp} values for some ionic compounds that are slightly soluble in water.

Table 18.2

Solubility Product Constants (K_{sp}) at 25°C

Ionic compound	K_{sp}	Ionic compound	K_{sp}	Ionic compound	K_{sp}
Halides		**Sulfates**		**Hydroxides**	
AgCl	1.8×10^{-10}	$PbSO_4$	6.3×10^{-7}	$Al(OH)_3$	3.0×10^{34}
AgBr	5.0×10^{-13}	$BaSO_4$	1.1×10^{-10}	$Zn(OH)_2$	3.0×10^{16}
AgI	8.3×10^{-17}	$CaSO_4$	2.4×10^{-5}	$Ca(OH)_2$	6.5×10^{-6}
$PbCl_2$	1.7×10^{-5}	**Sulfides**		$Mg(OH)_2$	7.1×10^{-12}
$PbBr_2$	2.1×10^{-6}	NiS	4.0×10^{-20}	$Fe(OH)_2$	7.9×10^{-16}
PbI_2	7.9×10^{-9}	CuS	8.0×10^{-37}	**Carbonates**	
PbF_2	3.6×10^{-8}	Ag_2S	8.0×10^{-51}	$CaCO_3$	4.5×10^{-9}
CaF_2	3.9×10^{-11}	ZnS	3.0×10^{-23}	$SrCO_3$	9.3×10^{-10}
Chromates		FeS	8.0×10^{-19}	$ZnCO_3$	1.0×10^{-10}
$PbCrO_4$	1.8×10^{-14}	CdS	1.0×10^{-27}	Ag_2CO_3	8.1×10^{-12}
Ag_2CrO_4	1.2×10^{-12}	PbS	3.0×10^{-28}	$BaCO_3$	5.0×10^{-9}

UbD Check for Understanding

What is the relationship between the solubility product constant and the solubility of a compound?

Assess students' understanding of solubility equilibrium by asking them to complete the following statement:

The more soluble a compound is, the _____ its solubility product constant. *(greater)*

ADJUST INSTRUCTION If students are misinterpreting the solubility constant, have students read the paragraph directly above Table 18.2. Have students think about how small the number of moles of ions in solution must be to give a product as small as the values in Table 18.2.

Sample Problem 18.6

Finding the Ion Concentrations in a Saturated Solution

What is the concentration of lead ions and chromate ions in a saturated solution of lead(II) chromate at 25°C? ($K_{sp} = 1.8 \times 10^{-14}$)

KNOWNS
$K_{sp} = 1.8 \times 10^{-14}$
$PbCrO_4(s) \rightleftharpoons Pb^{2+}(aq) + CrO_4^{2-}(aq)$

UNKNOWNS
$[Pb^{2+}] = ?\ M$
$[CrO_4^{2-}] = ?\ M$

1 Analyze **List the knowns and the unknowns.** Write the expression for K_{sp}. Then modify it so that there is a single unknown.

2 Calculate **Solve for the unknowns.**

Start with the general expression for the solubility product constant.

$K_{sp} = [A]^a \times [B]^b$

The exponent for each ion is 1.

Use the chemical equation to write the correct expression for K_{sp} for the reaction.

$K_{sp} = [Pb^{2+}] \times [CrO_4^{2-}] = 1.8 \times 10^{-14}$

At equilibrium, $[Pb^{2+}] = [CrO_4^{2-}]$

Substitute $[Pb^{2+}]$ for $[CrO_4^{2-}]$ in the expression to get an equation with one unknown.

$K_{sp} = [Pb^{2+}] \times [Pb^{2+}] = [Pb^{2+}]^2 = 1.8 \times 10^{-14}$

Solve for $[Pb^{2+}]$.

$[Pb^{2+}] = \sqrt{1.8 \times 10^{-14}}$

$[Pb^{2+}] = [CrO_4^{2-}] = 1.3 \times 10^{-7} M$

3 Evaluate **Does the result make sense?** Calculate $[Pb^{2+}] \times [CrO_4^{2-}]$ to evaluate the answer. The result is 1.7×10^{-14}, which is close to the value for K_{sp}. The result varies slightly from the actual value because the answers were rounded to two significant figures.

33. Lead(II) sulfide (PbS) has a K_{sp} value of 3.0×10^{-28}. What is the concentration of lead(II) ions in a saturated solution of PbS at 25°C?

Start by writing the equation for the dissociation of the solid ionic compound.

34. What is the concentration of calcium ions in a saturated calcium carbonate solution at 25°C? Use the K_{sp} value for calcium carbonate from Table 18.2.

Foundations for Math

SUBSTITUTION Tell students that when solving reaction rate equations, there are a lot of letters, subscripts, and superscripts involved and that the process for solving the equation may be easier if they use a variable to represent the components of the reaction.
In **Sample Problem 18.6**, let A represent $[Pb^{2+}]$ and let B represent $[CrO_4^{2-}]$. Then, the equation can be rewritten as $A \times B = 1.8 \times 10^{-14}$. Since $[Pb^{2+}] = [CrO_4^{2-}]$ at equilibrium, then $A = B$, and the equation becomes $A \times A = 1.8 \times 10^{-14}$. Now use algebra to solve for A.

$$A \times A = 1.8 \times 10^{-14}$$
$$A^2 = 1.8 \times 10^{-14}$$
$$\sqrt{A^2} = \sqrt{1.8 \times 10^{-14}}$$
$$A = 1.3 \times 10^{-7}$$

Use the value of the variable to answer the question:

$$[A] = [Pb^{2+}] = [CrO_4^{2-}] = 1.3 \times 10^{-7}$$

Explore

Class Activity

PURPOSE Students illustrate the solubilities of salts containing various anions.

MATERIALS calculator, paper, pencil, colored markers or highlighters

PROCEDURE Divide the class into groups of four students. Ask the groups to create color-coded tables illustrating the solubilities of salts containing various anions. For example, students can design separate tables for nitrates, sulfates, chlorides, sulfides, hydroxides, and carbonates. Have them use different colors in each table to show which elements form soluble compounds containing a given anion and which form insoluble compounds. Students should divide the tasks of looking up solubilities, designing the tables, and drawing the final tables. Remind students that the compounds listed in Table 18.2 are only a small sampling of possible compounds these anions can form.

Sample Practice Problems

What is the concentration of barium and sulfate ions in a saturated barium sulfate solution at 25°C?
$K_{sp} = 1.1 \times 10^{-10}$ *($1.0 \times 10^{-5} M$)*

Answers

FIGURE 18.18 No, because the concentration of AgCl is constant.

33. $2 \times 10^{-14} M$

34. $6.7 \times 10^{-5} M$

Explain

The Common Ion Effect

CHEMISTRY & YOU Only a tiny amount of the barium sulfate dissolves; most of it simply passes through the digestive system.

APPLY CONCEPTS Point out that the common ion effect is not a new concept, but an example of Le Châtelier's principle at work. Explain that adding an ion to an equilibrium system containing that ion will cause the equilibrium to shift in the direction that uses up the ion.

DRAW CONCLUSIONS Have students hypothesize how the common ion effect could be used to identify ions in solution. Suggest that they use Table 18.1 to find a common property of salts listed in Table 18.2. *(If a precipitate forms when a few drops of an unknown solution is added to a known saturated solution, the unknown solution may have an ion in common with the known solution, or ions in the two solutions may have combined to form an insoluble product.)* Point out that in either case, additional tests would need to be performed to determine the identity of the precipitate.

The Common Ion Effect

How can you predict whether precipitation will occur when two solutions are mixed?

In a saturated solution of lead(II) chromate, an equilibrium is established between the solid lead(II) chromate and its ions in solution.

$$PbCrO_4(s) \rightleftharpoons Pb^{2+}(aq) + CrO_4^{2-}(aq) \quad K_{sp} = 1.8 \times 10^{-14}$$

What would happen if you added some lead nitrate to this solution? Lead(II) nitrate, $Pb(NO_3)_2$, is soluble in water. So adding $Pb(NO_3)_2$ causes the concentration of lead ion to increase. The product of $[Pb^{2+}]$ and $[CrO_4^{2-}]$ would be greater than the K_{sp} for lead(II) chromate. The addition of lead ions is a stress on the equilibrium. Applying Le Châtelier's principle, the stress can be relieved if the reaction shifts to the left. Figure 18.19 shows the result. The excess lead ions combine with chromate ions in solution to form additional solid $PbCrO_4$. Lead(II) chromate continues to precipitate from the solution until the product of $[Pb^{2+}]$ and $[CrO_4^{2-}]$ once again equals 1.8×10^{-14}. The difference is that now the lead ions in solution come from two sources, $PbCrO_4$ and $Pb(NO_3)_2$.

K_{sp} for the original solution: $[Pb^{2+}][CrO_4^{2-}] = 1.8 \times 10^{-14}$

K_{sp} after addition of $Pb(NO_3)_2$: $[Pb^{2+}][CrO_4^{2-}] = 1.8 \times 10^{-14}$

CHEMISTRY & YOU

Q: *The K_{sp} of $BaSO_4$ is 1.1×10^{-10}. How can patients ingest the toxic $BaSO_4$ without being harmed?*

In this example, the lead ion is a common ion. A **common ion** is an ion that is found in both ionic compounds in a solution. The lowering of the solubility of an ionic compound as a result of the addition of a common ion is called the **common ion effect.** Chemists can use an ionic compound with a common ion to cause a solid to precipitate from solution. For the common ion effect to work, the added compound must be more soluble than the compound that is already in solution. Adding lead(II) nitrate to a saturated solution of $PbCrO_4$ causes the solubility of $PbCrO_4$ to decrease. Adding sodium chromate, Na_2CrO_4, to the solution would produce the same effect. The chromate ion is common to both salts, and Na_2CrO_4 is much more soluble in water than is $PbCrO_4$.

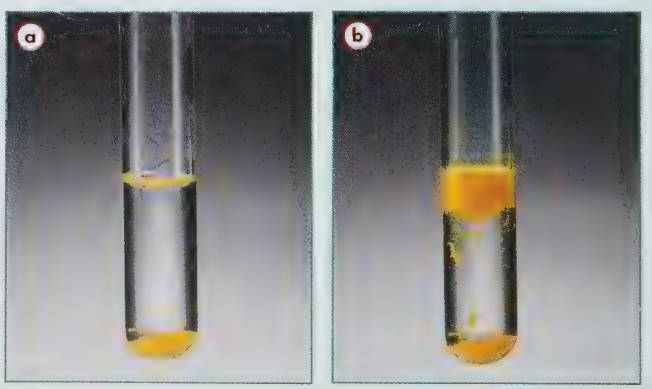


Figure 18.19 Lead(II) Chromate Lead(II) chromate, $PbCrO_4$, is slightly soluble in water. **a.** The yellow solid in the test tube is $PbCrO_4$. It cannot dissolve because the solution is saturated with Pb^{2+} and CrO_4^{2-} ions. **b.** Adding some lead(II) nitrate, $Pb(NO_3)_2$, to the solution causes $PbCrO_4$ to precipitate from solution, which increases the amount of solid $PbCrO_4$.
Relate Cause and Effect ***How does adding lead nitrate disturb the $PbCrO_4$ equilibrium?***

Differentiated Instruction

L1 STRUGGLING STUDENTS Pair students who have trouble with word problems with those who are proficient at algebra and problem solving. Have each pair work through the practice problems, taking turns being the lead solver. The lead student should explain the process being used to arrive at the solution.

ELL ENGLISH LANGUAGE LEARNERS Have students draw and label a diagram demonstrating the common ion effect with silver chloride and silver nitrate, using different colors to represent the silver ions from each compound. Have students use arrows to indicate the combination of the silver ions from silver nitrate with the chloride ions.

L3 ADVANCED STUDENTS Have students research and explain why photographic film is covered with a light-sensitive emulsion containing silver bromide.

Sample Problem 18.7

Finding Equilibrium Ion Concentrations in the Presence of a Common Ion

Small amounts of silver bromide can be added to the lenses used for eyeglasses. The silver bromide causes the lenses to darken in the presence of large amounts of UV light. The K_{sp} of silver bromide is 5.0×10^{-13}. What is the concentration of bromide ion in a 1.00-L saturated solution of AgBr to which 0.020 mol of $AgNO_3$ is added?

1 Analyze **List the knowns and the unknown.**

Use one unknown to express both $[Ag^+]$ and $[Br^-]$. Let x be the equilibrium concentration of bromide ion and $x + 0.020$ be the equilibrium concentration of silver ion.

KNOWNS

$K_{sp} = 5.0 \times 10^{-13}$

moles of $AgNO_3$ added $= 0.020$ mol

$AgBr(s) \rightleftharpoons Ag^+(aq) + Br^-(aq)$

UNKNOWN

$[Br^-] = ?\ M$

2 Calculate **Solve for the unknown.**

Write the expression for K_{sp}.

$$K_{sp} = [Ag^+] \times [Br^-]$$

Substitute x for $[Br^-]$ in the solubility product expression.

$$K_{sp} = [Ag^+] \times x$$

Rearrange the equation to solve for x.

$$x = \frac{K_{sp}}{[Ag^+]}$$

Based on the small value of K_{sp}, you can assume that x will be very small compared to 0.020. Thus, $[Ag^+] \approx 0.020\ M$.

Substitute the values for K_{sp} and $[Ag^+]$ in the expression and solve.

$$x = \frac{(5.0 \times 10^{-13})}{0.020}$$

$$[Br^-] = 2.5 \times 10^{-11} M$$

3 Evaluate **Does the result make sense?** The concentration of Br^- in a saturated solution of AgBr is $7.0 \times 10^{-7} M$ (the square root of the K_{sp}). It makes sense that the addition of $AgNO_3$ would lower the concentration of Br^- because the presence of a common ion, Ag^+, causes AgBr to precipitate from solution.

35. What is the concentration of sulfide ion in a 1.0-L solution of iron(II) sulfide to which 0.04 mol of iron(II) nitrate is added? The K_{sp} of FeS is 8×10^{-19}.

36. The K_{sp} of $SrSO_4$ is 3.2×10^{-7}. What is the equilibrium concentration of sulfate ion in a 1.0-L solution of strontium sulfate to which 0.10 mol of $Sr(CH_3CO_2)_2$ is added?

You can usually assume that the amount of the slightly soluble compound that dissociates is small compared to the amount of the common ion that is added.

Foundations for Math

CHECK YOUR ANSWER Remind students that checking their answers is a valuable way to know if their answer is reasonable. Remind students of the inverse properties of multiplication and division so they can quickly check their results.

In **Sample Problem 18.7** the quotient of $\frac{K_{sp}}{[Ag^+]} = 2.5 \times 10^{-11} M$. To check that the answer is correct, multiply the quotient by one of the factors. The product should be the other known factor.

Find $(0.020) \times (2.5 \times 10^{-11})$.

$(0.020) \times (2.5 \times 10^{-11}) = 5.0 \times 10^{-13}$

Since 5.0×10^{-13} is the other known factor, the answer checks.

Explore

Class Activity

PURPOSE Students hypothesize the result of mixing silver nitrate and silver chloride.

MATERIALS silver chloride, silver nitrate, 2 test tubes, dropper

PROCEDURE Prepare saturated solutions of silver chloride and silver nitrate in two test tubes. Write the solubility product constant expression for silver chloride on the board.

$$K_{sp} = [Ag^+] \times [Cl^-] = 1.8 \times 10^{-10}$$

Have students hypothesize what would occur if a few drops of the silver nitrate solution were added to the test tube containing the silver chloride. Add the drops of silver nitrate solution and ask students what they observe. *(A precipitate, silver chloride, comes out of solution.)* Explain that the value of $[Ag^+]$ increases in the K_{sp} expression as the silver nitrate is added, so that silver chloride must precipitate until the solubility product again equals K_{sp}.

Sample Practice Problem

What is the concentration of chloride ion in a 1.0-L solution of silver chloride to which 0.03 mol of silver nitrate has been added? The K_{sp} of AgCl is 1.0×10^{-10}. *(6.0×10^{-9})*

Answers

FIGURE 18.19 An increase in $Pb^{2+}(aq)$ shifts the equilibrium to the left, creating more $PbCrO_4(s)$.

35. $2 \times 10^{-17} M$

36. $3.2 \times 10^{-6} M$

Evaluate

Informal Assessment

Have students classify the salts in Table 18.2 on the basis of solubility. **Ask** What is the relationship between the solubility product constant and the relative solubility of a salt? *(The larger the solubility product constant, the more soluble the salt.)*

Reteach

Project a transparency of Table 18.1. Point out some salient features, for example, water is the solvent, and the last column is for exceptions to the first column. Ask students to look in Table 18.2 for examples of ions described as being slightly soluble in Table 18.1. Help students sketch a graph of the relationship between solubility product constants and solubility.

Figure 18.20
Formation of a Precipitate
As solutions of barium nitrate and sodium sulfate are mixed, a precipitate of $BaSO_4$ is formed.
Explain ***Why is barium sulfate the only compound that precipitates when the solutions are mixed?***

You can use the solubility product constant to predict whether a precipitate will form when two solutions are mixed. **A precipitate will form if the product of the concentrations of two ions in the mixture is greater than the K_{sp} value for the compound formed from the ions.** After the precipitate forms, the solution is saturated for that compound. If the product of the concentrations is less than the K_{sp} value, no precipitate will form and the solution is unsaturated.

Suppose you mix two solutions, 0.50 L of 0.002*M* $Ba(NO_3)_2$ and 0.50 L of 0.008*M* Na_2SO_4. The mixture will have a volume of one liter. The compound that might form a precipitate is barium sulfate ($BaSO_4$), which has a K_{sp} value of 1.1×10^{-10}. Precipitation will occur if the product of the concentrations of Ba^{2+} and SO_4^{2-} is greater than the K_{sp} value.

To predict whether a precipitate will form, you need to know the concentration of the ions after the solutions were mixed. During mixing, each solution is diluted with an equal volume of the other solution. So the concentrations of both Ba^{2+} and SO_4^{2-} will be half of their original concentrations. Therefore, in the combined solution, $[Ba^{2+}] = 0.001M$ and $[SO_4^{2-}] = 0.004M$. You can multiply these concentrations and compare the result with the K_{sp} value.

$$[Ba^{2+}] \times [SO_4^{2-}] = (0.001M) \times (0.004M) = 4 \times 10^{-6}$$

The calculated result is larger than the K_{sp} value for barium sulfate (1.1×10^{-10}). Therefore, $BaSO_4$ will precipitate from the solution. The process will continue until the product of the concentrations of the ions remaining in solution is equal to 1.1×10^{-10}. Figure 18.20 shows the mixing of the two solutions and the formation of the barium sulfate precipitate.

18.4 LessonCheck

37. Summarize What does the solubility product constant, K_{sp}, tell you about the solubility of a compound?

38. Identify What two values should you compare to predict whether a precipitate will form when two solutions are mixed?

39. Apply Concepts Write the solubility product expression for Ag_2CO_3.

40. Compare Which compound has the higher solubility: FeS ($K_{sp} = 8.0 \times 10^{-19}$) or CuS ($K_{sp} = 8.0 \times 10^{-37}$)?

41. Calculate What is the K_{sp} of nickel(II) sulfide if the equilibrium concentrations of Ni^{2+} and S^{2-} in a saturated solution of NiS are each $2 \times 10^{-10}M$?

42. Calculate What is the concentration of lead ions and sulfide ions in a saturated solution of lead sulfide (PbS) solution at 25°C? ($K_{sp} = 3.0 \times 10^{-28}$)

43. Calculate The K_{sp} value for barium sulfate is 1.1×10^{-10}. What is the sulfate-ion concentration of a 1.00 L saturated solution of $BaSO_4$ to which 0.015 mol of $Ba(NO_3)_2$ is added?

44. Predict Will a precipitate form when 500 mL of a 0.02*M* solution of $AgNO_3$ is mixed with 500 mL of a 0.001*M* solution of NaCl? Explain.

BIG IDEA REACTIONS

45. Explain how the common ion effect illustrates Le Châtelier's principle.

Lesson Check Answers

37. The smaller the K_{sp}, the lower the solubility of the compound.

38. If the product of the concentrations of two ions in a mixture is greater than the K_{sp} of the compound formed from the ions, a precipitate will form.

39. $[Ag^+]^2 \times [CO3_3^{2-}] = K_{sp}$

40. FeS

41. 4×10^{-20}

42. $2 \times 10^{-14}M$

43. $7.3 \times 10^{-9}M$

44. Yes; The product $[Ag^+] \times [Cl^-] = 0.01M \times 0.0005M = 5 \times 10^{-6}$ is greater than the K_{sp} of AgCl (1.8×10^{-10})

45. **BIG IDEA** Adding a common ion (a product in the dissolution expression) disturbs the equilibrium and causes a shift toward the reactant side of the expression.

18.5 Free Energy and Entropy

CHEMISTRY & YOU

Q: *How can a fire start on its own?* Sometimes a fire can occur without an external source of ignition, such as a match or an electrical spark. The fuel might be a pile of oily rags or a stack of hay that has not been thoroughly dried. *Spontaneous combustion* is the term used to describe these fires. In this lesson, you will learn about the conditions that can cause such a fire.

Key Questions

- *What are two characteristics of spontaneous reactions?*
- *What part does entropy play in a reaction?*
- *What two factors determine whether a reaction is spontaneous?*
- *How is the value of ΔG related to the spontaneity of a reaction?*

Vocabulary

- free energy
- spontaneous reaction
- nonspontaneous reaction
- entropy
- law of disorder

Free Energy and Spontaneous Reactions

What are two characteristics of spontaneous reactions?

Some of the energy released in a chemical reaction can be harnessed to do work, such as pushing the pistons in an internal-combustion engine. The energy that is available to do work is called **free energy.** Just because energy is available to do work, however, does not mean that it can be used efficiently. For example, an internal-combustion engine in a car is only about 30 percent efficient. That is, only about 30 percent of the free energy released as gasoline burns is used to move the car. The remaining 70 percent is lost as friction and waste heat. No process can be made 100 percent efficient. Even in living things, which are among the most efficient users of free energy, processes are seldom more than 70 percent efficient.

Spontaneous Versus Nonspontaneous Reactions Energy can be obtained from a reaction only if the reaction actually occurs. In other words, you can write a balanced equation for a chemical reaction, but the reaction may not actually take place. For example, you can write an equation for the decomposition of carbon dioxide to carbon and oxygen.

$$CO_2(g) \longrightarrow C(s) + O_2(g)$$

This equation, which represents the reverse of combustion, is balanced. However, experience tells you that this reaction does not tend to occur. Carbon and oxygen react to form carbon dioxide, not the reverse. The world of balanced chemical equations is really divided into two groups. One group contains equations representing reactions that actually occur. The other contains equations representing reactions that do not tend to occur, or at least not efficiently.

Focus on ELL

1 CONTENT AND LANGUAGE Present the following pairs of words in a T-chart: *endothermic* and *exothermic*, *spontaneous* and *nonspontaneous*, *order* and *disorder*, *forward* and *reverse*, *increase* and *decrease*, *absorb* and *release*, and *favorable* and *unfavorable*. Explain that the pairs are *antonyms*, word pairs with opposite meanings.

2 FRONTLOAD THE LESSON Have students describe their first or favorite fireworks display. Note that fireworks are examples of combustion reactions. Ask students if they recall any fireworks that might not have behaved as expected during the display. Explain that in this lesson they will learn why a firework may or may not explode.

3 COMPREHENSIBLE INPUT When discussing Figure 18.26, be sure that students understand that the length of the colored arrows represents the sum of their associated black arrows. Point out that black arrows will be shorter for reactions in which the colored arrows point in opposite directions.

Key Objectives

- **IDENTIFY** the two characteristics of spontaneous reactions.
- **IDENTIFY** the part entropy plays in a chemical reaction.
- **IDENTIFY** the two factors that determine whether a reaction is spontaneous.
- **DESCRIBE** how the value of ΔG is related to the spontaneity of a reaction.

Additional Resources

- Reading and Study Workbook, Lesson 18.5
- Probeware Laboratory Manual
- Virtual Chemistry Labs

Engage

CHEMISTRY & YOU Explain when a substance starts to combust without an external energy source, it is called spontaneous combustion. **Ask** Considering what you have learned about reactions so far, what factors do you think spontaneous chemical reactions have in common? *(Sample answers: reactions that have low activation energy; reactions that involve active elements such as alkali metals; combustion reactions above the kindling temperature; reactions that produce a precipitate.)*

Access Prior Knowledge

Begin a cluster diagram on an overhead relating the word *energy* to exothermic reactions, endothermic reactions, and the requirements for a chemical reaction to occur. Ask students to recall what they have learned about these three concepts in regard to energy.

Answers

FIGURE 18.20 Sodium nitrate is a soluble compound.

Foundations for Reading

BUILD VOCABULARY Have students write definitions for *spontaneous* and *nonspontaneous* and *order* and *disorder* in their own words. Guide students to consider the meaning of these words as they relate to human behavior.

READING STRATEGY Have students create a compare/contrast table to track similarities and differences between spontaneous and nonspontaneous reactions.

Explain

Free Energy and Spontaneous Reactions

MAKE A CONNECTION Convey to students that the words *force* and *work* both common and scientific meanings. Remind students that, in science, a *force* can be defined as a push or a pull, and is measured in newtons (N). *Work* is done on an object when a force is applied through a distance and the force is in the same direction as the distance moved. Work is measured in joules.

Point out that work is done on a gas when force is applied to reduce its volume. Rapidly expanding gases, such as those produced in an explosion, also do work. **Ask** Is work done on molecules when the temperature is raised or when chemical bonds are broken? *(yes, in both cases)* **Ask** How is energy related to work? *(Work and energy have the same units.)*

USE VISUALS Direct students to Figure 18.21. Explain that the highly spontaneous reactions in fireworks require very high initiation temperatures to produce the fast reaction rate observed. They also release a large quantity of free energy. Clarify, however, that spontaneous reactions are not directly related to reaction rate.

Misconception Alert

Students may think that a nonspontaneous reaction is one in which no products are formed. Explain that the difference between spontaneous and nonspontaneous reactions is the amount of products at equilibrium. Remind students that a reversible reaction under a given set of conditions has a both a spontaneous reaction and a nonspontaneous reaction.

Figure 18.21 Spontaneous Reaction Fireworks displays are the result of highly favored spontaneous reactions. A large quantity of free energy is released.

Some chemical reactions are spontaneous. A **spontaneous reaction** occurs naturally and favors the formation of products at the stated conditions. Figure 18.21 shows an example of a spontaneous reaction. **Spontaneous reactions produce large amounts of products and release free energy.** A chemical reaction that does not favor the formation of products at the stated conditions is called a **nonspontaneous reaction.** Such reactions produce little, if any, product.

Figure 18.22 Reversible Reaction A precipitate of cadmium sulfide forms spontaneously when solutions of sodium sulfide and cadmium nitrate are mixed. The reverse reaction is nonspontaneous.
Infer ***Is free energy released in this reaction?***

Reversible Reactions In nearly all reversible reactions, one reaction is favored over the other. Consider the decomposition of carbonic acid in water.

$$\underset{<1\%}{H_2CO_3(aq)} \rightleftharpoons \underset{>99\%}{CO_2(g) + H_2O(l)}$$

In the forward reaction, carbonic acid is the reactant. Suppose you could start with pure carbonic acid in water and let the system come to equilibrium. More than 99 percent of the reactant would be converted to the products carbon dioxide and water. These products are highly favored at equilibrium. The natural tendency is for carbonic acid to decompose to carbon dioxide and water. Thus, the forward reaction is spontaneous and releases free energy. In the reverse reaction, carbon dioxide and water are the reactants, and carbonic acid is the product. Suppose you allow a solution of carbon dioxide in water to come to equilibrium. Less than 1 percent of the reactants will combine to form carbonic acid. The reactants show little natural tendency to go to products. Thus, the combination of carbon dioxide and water to form carbonic acid is a nonspontaneous reaction.

Figure 18.22 shows another example of a reversible reaction. When solutions of cadmium nitrate and sodium sulfide are mixed, the products are aqueous sodium nitrate and solid yellow cadmium sulfide. Cadmium sulfide is highly favored. Thus, the forward reaction is spontaneous. The reverse reaction, the production of cadmium nitrate and sodium sulfide from cadmium sulfide and sodium nitrate, is nonspontaneous.

$$Cd(NO_3)_2(aq) + Na_2S(aq) \rightleftharpoons CdS(s) + 2NaNO_3(aq)$$

Differentiated Instruction

L1 LESS PROFICIENT READERS Clarify the concepts of free energy and energy efficiency. Steer students away from relating the words *free* and *efficient*. Explain that energy efficiency is a measure of the amount of free energy that is used to do work.

ELL ENGLISH LANGUAGE LEARNERS Provide students with a key for each symbol presented in this lesson. Include the various arrow symbols as well as delta (Δ). Encourage students to use these symbols when answering questions in the labs and in the assessments.

L3 ADVANCED STUDENTS As a preparation for biochemistry, have students write down a coupled reaction involving adenosine triphosphate (ATP). Have them research and explain why ATP has the ability to enter into various types of coupled reactions.

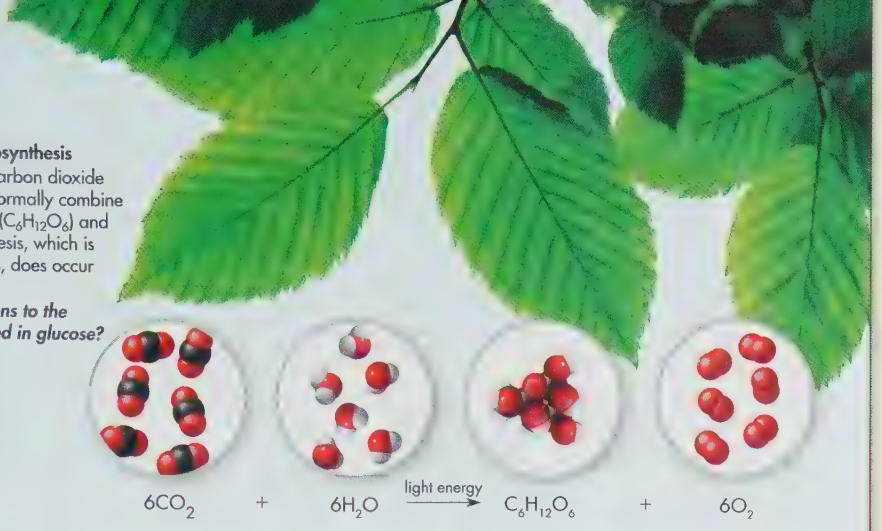

Figure 18.23 Photosynthesis
Outside of plants, carbon dioxide and water do not normally combine to produce glucose ($C_6H_{12}O_6$) and oxygen. Photosynthesis, which is a series of reactions, does occur in plants.
Infer ***What happens to the energy that is stored in glucose?***

The Rate of Spontaneous Reactions It is important to note that the terms *spontaneous* and *nonspontaneous* do not refer to the rate of a reaction. Some spontaneous reactions are so slow that they appear to be nonspontaneous. The reaction of table sugar and oxygen is an example of such a reaction.

$$C_{12}H_{22}O_{11} + 12O_2 \longrightarrow 12CO_2 + 11H_2O$$

Nothing appears to be happening in a bowl of sugar sitting on a table. You might assume that the reaction is nonspontaneous. In fact, the reaction is highly spontaneous, but at room temperature the reaction is so slow that it would take thousands of years for the reaction to reach completion. When you supply energy in the form of heat, the reaction is fast. Then it is obvious that the formation of carbon dioxide and water is highly favored.

Changing the conditions of a chemical reaction can affect more than the reaction rate. It can also affect whether a reaction will occur. A reaction that is nonspontaneous in one set of conditions may be spontaneous in other conditions. Consider the photosynthesis reaction, which is summarized in Figure 18.23. This multistep reaction takes place in plant leaves. This complex process could not happen without the energy supplied by sunlight. Other requirements include plant pigments, such as chlorophyll, that absorb the light energy.

Coupled Reactions Sometimes a nonspontaneous reaction can be made to occur if it is coupled to a spontaneous reaction. One reaction releases energy that is used by the other reaction. Coupled reactions are common in the complex biological processes that take place in living organisms. Within cells, a series of spontaneous reactions release the energy stored in glucose. Molecules in cells capture and transfer the free energy to nonspontaneous reactions, such as the formation of proteins. Chapter 24 describes these processes.

CHEMISTRY & YOU

Q: *Decomposition reactions that occur inside a pile of oily rags or a damp stack of hay cause heat to build up. If the heat cannot escape, the temperature within the pile or stack will rise. How can a rise in temperature cause a fire to start on its own? Hint: Think about the reaction of table sugar and oxygen.*

UbD Check for Understanding

The Essential Question **Why do some reactions occur naturally, and others do not?**

Assess students' knowledge about reactions by asking them to show you a thumbs-up for *true* and a thumbs-down for *false* for the following questions.

- Chemical reactions that occur naturally only occur in nature. *(false)*
- Spontaneous reactions occur without energy input. *(true)*
- A reaction that occurs naturally almost always releases free energy. *(true)*
- Any reaction that occurs immediately after the temperature is increased is a spontaneous reaction. *(false)*

ADJUST INSTRUCTION If students struggle to answer the questions, have them review the section on Free Energy and Spontaneous Reactions. As a class complete a T-chart listing characteristics of natural/unnatural reactions.

Explain

Misconception Alert

Students may think that any reaction that does not involve human involvement may occur spontaneously. Caution students that just because a process occurs in nature does not necessarily mean that the reaction occurs spontaneously.

CRITICAL THINKING Have students consider the combustion of glucose to produce carbon dioxide and water. Point out that the reverse of this reaction is the overall reaction for photosynthesis, the process by which plants make glucose using carbon dioxide and water. Ask students to consider the magnitude of the free-energy value for the photosynthesis reaction, +2868 kJ/mol. **Ask** Under ordinary conditions, do you think photosynthesis is a spontaneous reaction or a nonspontaneous reaction? Why? *(nonspontaneous; because it requires an energy source)*

Answers

FIGURE 18.22 Free energy is released because the reaction is spontaneous.

FIGURE 18.23 It is used later during cellular respiration.

Explain

Entropy

START A CONVERSATION Ask students to raise their hands and state a word that is a synonym of order. *(orderliness, tidiness, cleanliness, pattern, organization, distribution, regulation)* Neatly write each word on the board. Next repeat this activity but tell the class they have 30 seconds to shout out words that are synonyms of disorder. *(chaos, confusion, messiness, turmoil, untidiness, unruliness, disarray, clutter)* Quickly and haphazardly write the words on the board.

Ask Which activity did you enjoy more, the orderly brainstorming session or the disorderly brainstorming session? Why? *(Sample answers: disorderly; it was more fun, we could be loud, we could speak whenever we wanted)* Explain that the way in which students enjoyed the chaos of the brainstorming session is similar to the way in which a chemical reaction proceeds. Convey to the class that molecules have a natural tendency to move away from order toward disorder. State that molecules, like students, would rather be able to act unruly too.

INTERPRET DIAGRAMS Have students study Figure 18.24. Before students read the caption, **Ask** Do you think dogs would rather be on a leash or would rather be running freely on their own? *(freely on their own)* **Ask** What do you think the purpose is for each picture? *(to show order and disorder)*

USE AN ANALOGY Ask students to describe other human-made or natural environments that are analogous to the concept of entropy. *(Sample answers: weeds in a garden, books dumped haphazardly on library shelves, children at recess, fans entering a stadium, a table of sweaters on a sale day, volcanoes, the contents of a house after a flood or earthquake)*

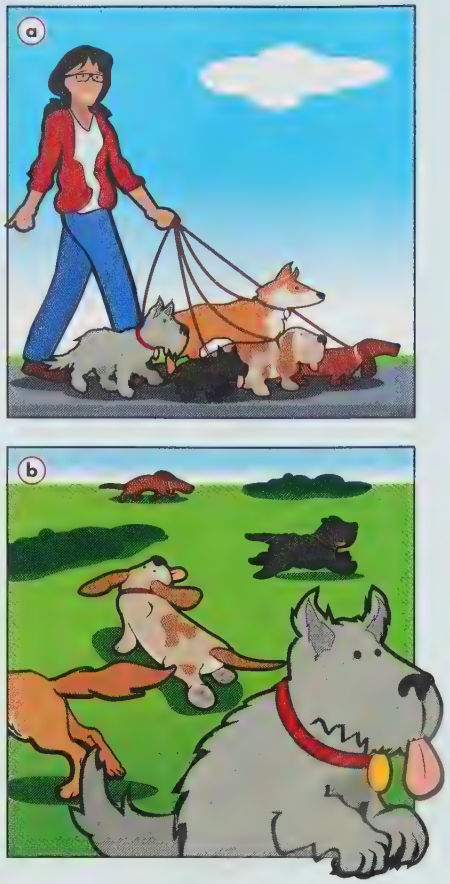

Figure 18.24 Order and Disorder
A dog walker with several dogs could represent relative order and disorder. **a.** All of the dogs are on leashes and are strolling orderly along the path. **b.** The dogs are no longer wearing leashes and are running freely. This situation represents disorder.

Learn more about entropy online.

Entropy

What part does entropy play in a reaction?

Recall that changes in the heat content, or enthalpy, of a system occur with most chemical and physical processes. These changes help determine whether a process is spontaneous. For example, the combustion of carbon (graphite) is exothermic. The reaction releases 393.5 kJ for each mole of carbon burned. The reaction is spontaneous.

$$C(s, \text{graphite}) + O_2(g) \longrightarrow CO_2(g) + 393.5 \text{ kJ/mol}$$

You might expect that only exothermic reactions are spontaneous. Some processes, however, are spontaneous even though they absorb heat. Consider what happens as ice melts. As it changes from a solid to a liquid, 1 mol of ice at 25°C absorbs 6.0 kJ of heat from its surroundings. The liquid water has a higher energy than the solid ice.

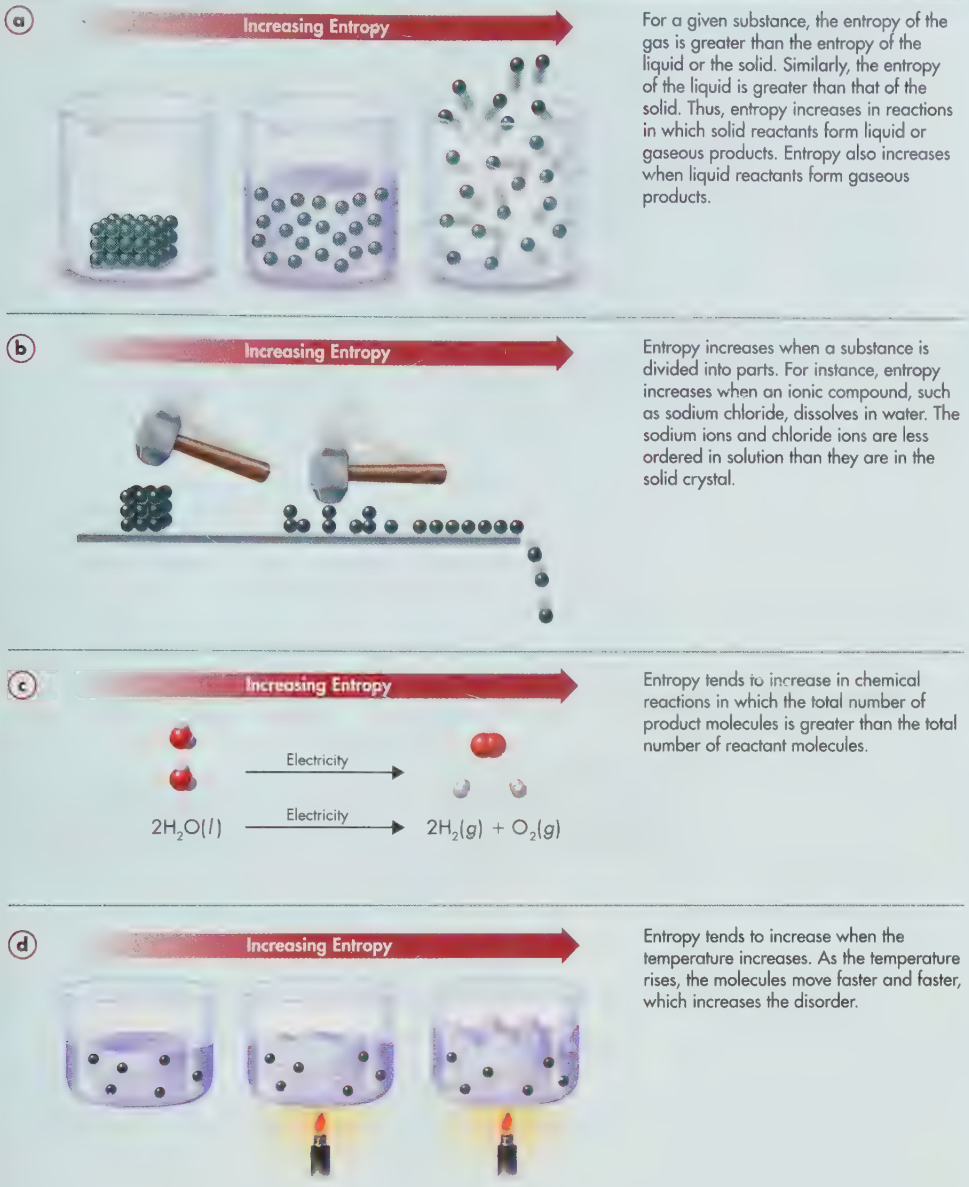
$$H_2O(s) + 6.0 \text{ kJ/mol} \longrightarrow H_2O(l)$$

If you consider only enthalpy changes, it is difficult to explain why the ice melts. In spontaneous processes, the rule seems to be that the direction of energy change is from higher energy to lower energy. Yet the ice does melt. Some factor other than the enthalpy change must help determine whether a physical or chemical process is spontaneous.

The other factor is related to order. You are probably familiar with everyday ideas about order and disorder. For example, a handful of marbles is relatively ordered in the sense that all the marbles are collected in one place. If the marbles are dropped, it is not probable that they will end up in the same neat arrangement. Instead, the marbles scatter on the ground. They become disordered. Scattered marbles have a higher entropy than a handful of marbles. **Entropy** is a measure of the disorder of a system. Figure 18.24 provides another comparison of relative order and disorder.

The **law of disorder** states that the natural tendency is for systems to move in the direction of increasing disorder or randomness. You are probably familiar with this tendency. For example, you start the school year with an empty locker that you gradually fill with items. For a few weeks, it is easy to find items in your locker. Over time, your locker may tend to become more disordered unless you put energy (work) into maintaining the order.

The law of disorder also applies at the level of atoms and molecules. So entropy can affect the direction of a reaction. **Reactions in which entropy increases as reactants form products tend to be favored.** Figure 18.25 provides some general rules to help you predict the effect of entropy on a reaction.



Professional Development Note

Origin of Entropy

The term *entropy* was coined by the German physicist Rudolf Clausius in 1865. He used the term to describe the portion of free energy that is unavoidably lost as waste heat. Clausius pointed out that in any process involving the flow of energy, there is always some loss, so the entropy of the universe is always increasing.

630 Chapter 18 • Lesson 5

Figure 18.25 Entropy
Here are four examples of changes that can increase the entropy of a system.

For a given substance, the entropy of the gas is greater than the entropy of the liquid or the solid. Similarly, the entropy of the liquid is greater than that of the solid. Thus, entropy increases in reactions in which solid reactants form liquid or gaseous products. Entropy also increases when liquid reactants form gaseous products.

Entropy increases when a substance is divided into parts. For instance, entropy increases when an ionic compound, such as sodium chloride, dissolves in water. The sodium ions and chloride ions are less ordered in solution than they are in the solid crystal.

Entropy tends to increase in chemical reactions in which the total number of product molecules is greater than the total number of reactant molecules.

Entropy tends to increase when the temperature increases. As the temperature rises, the molecules move faster and faster, which increases the disorder.

Differentiated Instruction

ELL ENGLISH LANGUAGE LEARNERS Terms such as *entropy* and *enthalpy* may be confusing to English language learners due to their similar sounds. When discussing these topics, pair each term with a descriptive phrase such as "molecular disorder" for entropy and "heat content" for enthalpy to help them distinguish which term is being used.

L1 LESS PROFICIENT READERS Prove the concept that a system moves more toward disorder than order by giving each student a packet of salt or pepper. Ask students to open their packet and pour the contents into something else without losing one particle. Have students describe the difficulty in doing this, and guide them to understand how the particles naturally moved toward disorder rather than order.

L3 ADVANCED STUDENTS State that entropy decreases in the reaction of iron, air, and water to form rust. Have students explain why this reaction is spontaneous. *(An ordered solid (Fe) and a less-ordered gas (O_2) release enough energy to balance the production of a more-ordered solid (Fe_2O_3) in the presence of a catalyst (H_2O).)*

Explore

Teacher Demo

PURPOSE Students infer the relative magnitude of the entropy of water in different states.

MATERIALS block of ice, beaker of water, rapidly boiling water, hot plate

PROCEDURE Place a block of ice, a beaker of water, and a beaker of rapidly boiling water in front of the class. Explain that in standard conditions, the natural tendency of the solid form of water is to turn to liquid and the natural tendency of the liquid form of water is to turn to vapor. **Ask** Which state of matter has the least entropy? *(the block of ice)* The greatest entropy? (*water vapor*) Why? *(In solid ice, the water molecules are highly ordered in a lattice. In liquid water, despite the hydrogen bonding between molecules, the molecules are relatively free to move around. In the water vapor produced by boiling water, randomness is greatly increased because the water molecules are able to move freely.)*

Extend

Connect to METEOROLOGY

Ask for a show of hands of students who have heard of the *butterfly effect*. Meteorologists once joked that the fluttering of a single butterfly's wings on one day in one part of the world creates a tiny disturbance in the air that ultimately results in completely altering weather patterns several months into the future. Explain that the butterfly effect has become a meteorological metaphor for chaos theory, a branch of mathematics devoted to the study of changes in systems with sensitive initial conditions. The butterfly effect is used to explain why weather can be so accurately predicted 24 hours into the future, but forecasts for a week to 10 days later often bear little resemblance to the actual weather events on those days. Have students demonstrate the butterfly effect by making a record of the day's weather forecast, making note of the 24-hour, 2-day, and 7- or 10-day forecast. Have students track the actual weather events that occur on each day and compare them back to the original forecast, then present their findings to the class.

Interested students may also enjoy reading the book *Chaos: Making a New Science* by James Gleick. The book is a non-technical, entertaining account of how chaos theory was discovered.

LESSON 18.5

Explain

Enthalpy and Entropy

APPLY CONCEPTS Explain that evidence suggests that Earth is being warmed because of the enhanced greenhouse effect, which is largely due to the release into the atmosphere of CO_2 produced by combustion. Another aspect of the greenhouse effect that relates to the topic of spontaneity is the increase in the quantity of atmospheric CO_2 gas that would occur if the oceans became warmer.

Remind students that the dissolution of CO_2 in bodies of water is an important part of the carbon cycle. However, CO_2, like all other gases, is less soluble in warm ocean water than in cool ocean water. There is concern that if the oceans become warmer, more CO_2 would be released into the atmosphere. In warmer oceans, the process whereby CO_2 dissolves in ocean water would become nonspontaneous, and the reverse process, the release of CO_2 gas, would become spontaneous. Guide students to understand that if this occurred, then the increased temperature would cause even more CO_2 release, which would further increase temperature, and the cycle would continue on.

Connect to CHEMICAL ENGINEERING

Explain that thermodynamics is the study of the relationship between heat, work, and energy. Although a complex science, it can generally be summarized by the three laws of thermodynamics. The British scientist and author C.P. Snow used a common sense approach for remembering the three laws of thermodynamics. Have students research the actual laws of thermodynamics and provide a statement explaining each of C.P. Snow's analogies:

- **Law 1:** You cannot win. *(The total energy of a system remains constant, even if it is converted from one form to another.)*
- **Law 2:** You cannot break even. *(Heat naturally flows in the direction of a hotter region to a cooler region, but not the other way around; You cannot return to the same energy state, because the disorder of a system tends to increase.)*
- **Law 3:** You cannot get out of the game. *(Since molecules are never completely at rest, absolute zero is impossible to reach since there will always be some type of disorder.)*

Enthalpy and Entropy

What two factors determine whether a reaction is spontaneous?

In every chemical reaction, heat is either released or absorbed. In every reaction, entropy either increases or decreases. How do these two factors affect the course of a reaction? **The size and direction of enthalpy changes and entropy changes together determine whether a reaction is spontaneous.**

Consider an exothermic reaction in which entropy increases. The reaction will be spontaneous because both factors are favorable. The combustion of carbon is an example. The reaction is exothermic, and entropy increases as solid carbon forms gaseous carbon dioxide. Now consider the reverse reaction in which carbon dioxide reacts to form carbon and oxygen. The reaction absorbs heat, and the entropy decreases as a solid is formed from gases. So the reaction must be nonspontaneous.

A reaction can be spontaneous if a decrease in entropy is offset by a large release of heat. A reaction can also be spontaneous if an increase in enthalpy is offset by an increase in entropy. Recall the example of ice melting. The change in enthalpy is not favorable because heat is absorbed. The change in entropy is favorable because a solid is changing to a liquid. Even though heat is absorbed, the melting of ice is spontaneous above 0°C. At such temperatures, the absorption of heat is sufficiently offset by a favorable entropy change. Table 18.3 summarizes the effect of enthalpy and entropy changes on the spontaneity of reactions.

You can also use enthalpy changes and entropy changes to determine whether a reaction is nonspontaneous. Consider a reaction when heat is absorbed and entropy decreases. In that case, both changes are unfavorable. Neither change favors the formation of products. For some exothermic reactions, the decrease in entropy is large enough to offset the favorable enthalpy change. In that case, the reaction is not spontaneous. Finally, a reaction that absorbs heat could have an increase in entropy that is too small to offset the unfavorable enthalpy change. Figure 18.26 uses visuals to show the results of six possible combinations of an enthalpy change and an entropy change.

Table 18.3

How Enthalpy Changes and Entropy Changes Affect Reaction Spontaneity

Enthalpy change	Entropy change	Is the reaction spontaneous?
Decreases (exothermic)	Increases (more disorder in products than in reactants)	Yes
Increases (endothermic)	Increases	Only if unfavorable enthalpy change is offset by favorable entropy change
Decreases (exothermic)	Decreases (less disorder in products than in reactants)	Only if unfavorable entropy change is offset by favorable enthalpy change
Increases (endothermic)	Decreases	No

Professional Development Note

The Evolution of Thermodynamics

Throughout the nineteenth century many scientists studied machinery and efficiency. The hope was to find a way to efficiently convert all of the heat produced by a machine into work. This would have resulted in a machine that could be powered by its own recycled heat, producing a boundless cycle of work, or perpetual motion. Unfortunately what scientist discovered did not lead to a perpetual-motion machine. Instead their findings led to a solid understanding of the relationship between heat, energy, and work in a system, hence the laws of thermodynamics.

The first law states that energy can neither be created nor destroyed, and is also known as the Law of Conservation of Energy. The second law states that in an isolated system, natural processes are spontaneous when they lead to an increase in disorder. The third law states that as temperature approaches absolute zero, the entropy of a system approaches a constant minimum.

Figure 18.26 Enthalpy and Entropy
The combination of the enthalpy change and the change in entropy for a reaction determines whether or not the reaction is spontaneous.
Summarize ***Explain why a spontaneous reaction can occur when one factor is unfavorable but not when both factors are unfavorable.***

UbD Check for Understanding

The Essential Question **What is the role of energy in chemical reactions?**

Ask students whether each reaction described in the statements below is spontaneous or nonspontaneous

- An endothermic reaction occurs that has a large entropy increase that offsets the enthalpy change. *(spontaneous)*
- A reaction is exothermic with an increase in entropy. *(+ spontaneous)*
- An endothermic reaction results in a decrease in entropy. *(– nonspontaneous)*

ADJUST INSTRUCTION Have students review Table 18.3 and Figure 18.26. Then have them revisit their incorrect answers.

Explore

Teacher Demo

PURPOSE Students observe a spontaneous reaction with a negative ΔH and a positive ΔS.

MATERIALS 0.1*M* solution of $KMnO_4$ in 0.1*M* HCl, graduated cylinder, 1000-mL beaker, thermometer, 20 mL of 30% H_2O_2, watch glass, splint, matches

SAFETY Wear gloves and safety goggles. Potassium permanganate is a powerful oxidizing agent and a strong skin irritant. The manganese ion is considered hazardous waste and must be disposed of in compliance with local regulations.

PROCEDURE Transfer 100 mL of the $KMnO_4$ solution to a 1000-mL beaker. Record its temperature. With a graduated cylinder, measure 20 mL of 30% H_2O_2. (Use a more dilute solution for a less vigorous reaction.) Record its temperature. Add the peroxide to the permanganate and cover the beaker with a watch glass. Record the temperature when the most vigorous reaction has subsided. Test the gas produced with a glowing splint.

ANALYZE AND CONCLUDE Write on the board the chemical reaction that was demonstrated.

$$2MnO_4^-(aq) + 5H_2O_2(l) + 6H^+(aq) \rightarrow 2Mn^{2+}(aq) + 8H_2O(l) + 5O_2(g).$$

Ask Was the reaction spontaneous? *(yes)* **Ask** Is the change in free energy positive or negative? Why? *(ΔG is negative since spontaneous reactions release free energy.)* **Ask** Is the entropy change positive or negative? How do you know? *(positive, because a gas is produced.)* **Ask** Considering the free-energy equation, $\Delta G = \Delta H - T\Delta S$, and the temperature change, what can you conclude about the change in enthalpy at room temperature? *(ΔH is negative at room temperature.)*

Answers

FIGURE 18.26 Both factors (changes in enthalpy and entropy) together determine the spontaneity of the reaction. If both factors are unfavorable, the reaction is not spontaneous. But, if one of the factors is favorable, it can offset the unfavorable factor.

Explain

Free Energy Change

DRAW CONCLUSIONS Point out that free energy refers to more than just the enthalpy change that occurs in a chemical reaction; it combines the change in enthalpy with the change in entropy. Explain that it is usually assumed that ΔH and ΔS are constant for the same reactions at different temperatures so, the contribution to the $T\Delta S$ term in the free energy equation comes mostly from the temperature itself.

Evaluate

Informal Assessment

Have students pair up to review what they have learned. One student should explain the significance of positive and negative changes in entropy. The pair then should evaluate the explanation for defects. The second student should then explain how the values of ΔG, ΔH, and ΔS determine whether a reaction is spontaneous. Again, the students should evaluate the explanation. You may wish to write the following questions on the board as a guide for discussion:

- What energy changes occur during a reaction that favors spontaneity? *(changes in which heat is released and entropy increases)*
- Under what conditions is a reaction least likely to be spontaneous? *(when heat is absorbed and entropy decreases)*
- What happens when one changes favors spontaneity and one change does not? *(The relative strengths of the opposing changes determine the outcome.)*

Then have students complete the 18.5 Lesson Check.

Reteach

Rewrite Table 18.3 on the board, inserting an extra column labeled *Temperature change* between the second and third columns, and relabeling the fourth column *Free energy change*. Add the appropriate conditions to the temperature column necessary to make the fourth column true.

Free Energy Change

How is the value of ΔG related to the spontaneity of a reaction?

Free energy is often expressed as Gibbs free energy. This term is named for Josiah Gibbs, the scientist who defined this thermodynamic property. The symbol for Gibbs free energy is G. Free energy can either be released or absorbed during a physical or chemical process. The equation below is used to calculate the change in Gibbs free energy (ΔG). ΔS is the change in entropy, ΔH is the change in enthalpy, and T is the temperature in kelvins.

$$\Delta G = \Delta H - T\Delta S$$

The equation provides a way to quantify the effect of enthalpy changes and entropy changes on a process. Recall that spontaneous processes release free energy, which decreases the amount of free energy in the system. In contrast, work must be done for a nonspontaneous process to occur. So the amount of free energy in the system increases. Thus, the value of ΔG indicates whether a process is spontaneous at a given temperature. **When the value of ΔG is negative, a process is spontaneous. When the value is positive, a process is nonspontaneous.**

A change in temperature can affect the spontaneity of a reaction. Consider the decomposition of solid calcium carbonate.

$$CaCO_3(s) + 178\ kJ \longrightarrow CaO(s) + CO_2(g)$$

In this reaction, entropy increases because one of the products is a gas. However, the reaction absorbs heat. At ordinary temperatures, the increase in entropy is not large enough to offset the unfavorable enthalpy change. Thus, the reaction is nonspontaneous at ordinary temperatures. However, in the equation, ΔS is multiplied by T. So the effect of entropy is magnified as the temperature rises. At temperatures above 850°C, $T\Delta S$ can offset ΔH, and the reaction becomes spontaneous.

18.5 LessonCheck

46. **Review** What two characteristics do all spontaneous reactions share?

47. **Explain** How can you use entropy to determine whether a chemical reaction is more or less likely to be spontaneous?

48. **Review** What two factors determine the spontaneity of a chemical reaction?

49. **Summarize** When the Gibbs free-energy change for a process is negative, what does this tell you about the process?

50. **Define** What is free energy?

51. **Draw Conclusions** Suppose the products of a reaction are more ordered than the reactants. Is the entropy change favorable or unfavorable?

52. **Explain** How can a reaction be spontaneous at some conditions but nonspontaneous at other conditions?

53. **Infer** Nitroglycerine decomposes as follows:

$$4C_3H_5(NO_3)_3(l) \longrightarrow 6N_2(g) + O_2(g) + 12CO_2(g) + 10H_2O(g)$$

The ΔH value for this reaction is -1427 kJ/mol. Use what you know about enthalpy and entropy to explain why this reaction is so explosive.

Lesson Check Answers

46. They produce substantial amounts of products at equilibrium and release free energy.

47. An increase in entropy favors a spontaneous reaction; a decrease favors a nonspontaneous reaction.

48. The size and direction of enthalpy and entropy changes together determine whether a reaction is spontaneous.

49. The reaction is spontaneous.

50. the energy available to do work

51. unfavorable

52. A change in state of a reactant, due to change in temperature or pressure, may change the balance between ΔS and ΔH.

53. The reaction of nitroglycerine releases 1427 kJ of heat, and in the process, converts 4 mol of a liquid into 29 mol of four different gases. Thus, both enthalpy and entropy changes favor spontaneity.

Small-Scale Lab

Enthalpy and Entropy

Purpose

To observe and measure energy changes during the formation of a solution and to describe and explain these changes in terms of enthalpy and entropy

Materials

- alcohol thermometer
- four 1-oz plastic cups
- plastic spoon
- sodium chloride
- ammonium chloride
- calcium chloride
- water
- crushed ice
- stirring rod

Procedure

1. Make a data table like the one below on a separate sheet of paper.

2. Place two level spoonfuls of water in one plastic cup. Measure and record the water temperature (T_1).

3. Dry the spoon. Then, add one level spoonful of NaCl to the cup. Stir gently with the thermometer.

4. Record the highest or lowest temperature that results (T_2).

5. Rinse the thermometer and spoon.

6. Repeat Steps 2–5, using NH_4Cl and $CaCl_2$.

Mixture	T_1	T_2	ΔT
$NaCl(s) + H_2O(l)$			
$NH_4Cl(s) + H_2O(l)$			
$CaCl_2(s) + H_2O(l)$			

Analyze and Conclude

1. Calculate Determine ΔT for each mixture using the following equation: $\Delta T = T_2 - T_1$

2. Observe An exothermic process releases heat. An endothermic process absorbs heat. In which mixture was the process of dissolving endothermic? In which mixture was the process exothermic? In which mixture, was heat neither released nor absorbed? Which solution(s) had little or no change in temperature?

3. Describe This is the equation for the dissociation of NaCl in water:

$$NaCl(s) \longrightarrow Na^+(aq) + Cl^-(aq)$$

Write similar ionic equations to show how NH_4Cl and $CaCl_2$ dissociate in water. Include heat as a reactant or a product in each equation.

4. Draw Conclusions When a solid dissolves in water, does entropy increase or decrease? Explain your reasoning.

5. Relate Cause and Effect Both the entropy change and the enthalpy change were favorable for a spontaneous change in which mixture? In which mixture was one change favorable and the other unfavorable for a spontaneous change? Explain why the change still happened?

You're the Chemist

1. Analyze Data Mix a tablespoon of crushed ice with a tablespoon of NaCl. Stir gently with a stirring rod. Then measure and record the lowest temperature reached. Compare the temperature change for this mixture with the results for the mixture of NaCl and liquid water.

2. Analyze Data Explain what you observed in the first activity. *Hint:* Is the process of melting ice exothermic or endothermic?

3. Design an Experiment Will the results be the same when an ionic compound other than NaCl is mixed with crushed ice? Try doing Activity 1 with NH_4Cl and $CaCl_2$.

Focus on ELL

4 ENABLE LANGUAGE PRODUCTION Have students work in groups of varied language proficiencies, so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING

LOW Clarify the procedures by demonstrating that the same process is to be followed 3 times; only the solid compound will change.

HIGH Provide students with a data table similar to the one in the lab but add an additional column labeled *Heat*. Tell them to write + for endothermic, – for exothermic, and 0 for neither in the *Heat* column.

INTERMEDIATE: LOW/HIGH Have students predict which equation will give off heat, absorb heat, or neither. Ask them to compare the actual result with their prediction. Allow students to orally present their results.

ADVANCED: LOW/HIGH Provide groups with reformatted Analyze and Conclude questions. Reformat the multi-part questions so each question is on a separate line.

Explore

Small-Scale Lab

OBJECTIVE After completing this lab, students will be able to:

- investigate the energy associated with chemical reactions;
- relate changes to exothermic and endothermic reactions.

MATERIALS NaCl, NH_4Cl, $CaCl_2$, alcohol thermometer, 4 1-oz. plastic cups, plastic spoon, crushed ice, water, stirring rod. Optional solids: KCl, $NaHCO_3$, Na_3PO_4

CLASS TIME 40 minutes

SAFETY Use small alcohol thermometers. If students are careful, they can use the thermometers to gently stir the contents of the plastic cup. Remind students of the hazard posed by broken glass. Never use mercury thermometers due to their poisonous contents. Look for a research lab that will trade alcohol thermometers for mercury thermometers.

Analyze and Conclude

1. Sample data for ΔT: **a.** 0°C; **b.** –16°C; **c.** +32°C

2. $NH_4Cl + H_2O$ is endothermic. ΔH is positive. $CaCl_2 + H_2O$ is exothermic. ΔH is negative. $NaCl + H_2O$ is neither endothermic nor exothermic. ΔH is close to 0.

3. heat + $NH_4Cl(s) \rightarrow NH_4^+(aq) + Cl^-(aq)$

$CaCl_2(s) \rightarrow Ca^{2+}(aq) + 2Cl^-(aq)$ + heat

4. Entropy usually increases during solvation. ΔS is positive in each case.

5. $NH_4Cl + H_2O$; $CaCl_2 + H_2O$; The change still happened because the favorable change in entropy outweighed the unfavorable enthalpy change.

You're the Chemist

1. The ice mixture has a larger change in temperature. The temperature can drop as much as 15°C.

2. The melting of ice is endothermic. Endothermic processes absorb heat and cool the environment.

3. Salts such as KCl, $NaHCO_3$, and Na_3PO_4 dissolve with little or no change in temperature.

ENRICHMENT Have students use and then dissect a chemical heat pack that uses sodium acetate and stainless steel. **Ask:** What process occurs that makes the heat pack an exothermic process? *(crystallization of sodium acetate)* What is the purpose of the steel? *(acts as a catalyst)*

STUDY GUIDE

Evaluate

Review and Assessment Resources

WALK-THRU TUTORIALS Each of the Math Tune-Up problems on the following page has an animated step-by-step tutorial that explains the problem-solving strategy in detail.

PROBLEM SETS Have students practice more problems using the Chapter 18 Online Problem Set.

MATH SKILLS Have struggling students practice manipulating algebraic equations using the MathXL learning module.

VIRTUAL LABS Have students complete the virtual lab *Enthalpy and Entropy* as an in-class or take home assignment to help reinforce the concepts of enthalpy, entropy, and free energy.

Study Tip

SWITCH TASKS When you feel yourself losing focus, switch the type of task you are working on, the subject that you are studying, or the environment that you are in. Take a break and walk around a bit. Stop studying when you are no longer being productive.

18 Study Guide

BIG IDEAS
REACTIONS, MATTER AND ENERGY

The rate of a chemical reaction can be controlled by adjusting temperature, concentration, or particle size. Adding a catalyst speeds up a reaction by lowering the activation energy. Energy is released in some reactions and absorbed in others. Changes in enthalpy and entropy can be used to explain why some reactions occur naturally and others do not.

18.1 Rates of Reaction

- In chemistry, the rate of a chemical reaction, or the reaction rate, is usually expressed as the change in the amount of reactant or product per unit time.
- Factors that can affect the rate of a chemical reaction are temperature, concentration, particle size, and the use of a catalyst.

- rate (595)
- collision theory (596)
- activation energy (596)
- activated complex (596)
- inhibitor (601)

18.2 The Progress of Chemical Reactions

- The value of the specific rate constant, k, in a rate law is large if products form quickly; the value is small if the products form slowly.
- Most chemical reactions consist of two or more elementary reactions.

- rate law (604)
- specific rate constant (604)
- first-order reaction (605)
- elementary reaction (607)
- reaction mechanism (607)
- intermediate (607)

18.3 Reversible Reactions and Equilibrium

- At chemical equilibrium, both the forward and reverse reactions continue, but because their rates are equal, no net change occurs in the concentrations of the reaction components.
- Stresses that upset the equilibrium of a chemical system include changes in concentration of reactants or products, changes in temperature, and changes in pressure.
- The size of the equilibrium constant indicates whether reactants or products are more common at equilibrium.

- reversible reaction (609)
- chemical equilibrium (610)
- equilibrium position (611)
- Le Châtelier's principle (612)
- equilibrium constant (616)

18.4 Solubility Equilibrium

- The smaller the value of the solubility product constant, the lower the solubility of the compound.
- A precipitate will form if the product of the concentrations of two ions in the mixture is greater than the K_{sp} value of the compound formed from the ions.

- solubility product constant (622)
- common ion (624)
- common ion effect (624)

18.5 Free Energy and Entropy

- Spontaneous reactions produce large amounts of products and release free energy.
- Reactions in which entropy increases as reactants form products tend to be favored.
- The size and direction of enthalpy changes and entropy changes together determine whether a reaction is spontaneous.
- When the value of ΔG is negative, a process is spontaneous. When the value is positive, a process is nonspontaneous.

- free energy (627)
- spontaneous reaction (628)
- nonspontaneous reaction (628)
- entropy (630)
- law of disorder (630)

Key Equations

$$\text{Rate} = \frac{\Delta A}{\Delta t} = k \times [\text{A}] \qquad \text{Rate} = k[\text{A}]^x[\text{B}]^y$$

$$K_{eq} = \frac{[\text{C}]^c \times [\text{D}]^d}{[\text{A}]^a \times [\text{B}]^b}$$

$$K_{sp} = [\text{A}]^a \times [\text{B}]^b$$

$$\Delta G = \Delta H - T\Delta S$$

UbD Performance Tasks

DIRECT ORDER: Create or download a computer program for your graphing calculator that can be used to determine the order of a chemical reaction. Create a mini-manual detailing the instructions for how to operate the program. The manual should include a cover page, a table of contents, an index defining concept vocabulary, a listing of the information needed about a chemical reaction, and step-by-step keystroke guidelines for operating the program. The manual should also include an example problem, as well as two to three practice problems.

NATURALLY IMPULSIVE: Research and find a reaction that occurs spontaneously in nature. List the reactants and the products of the reaction. Describe how the reaction takes place and the rate of the reaction. Include a graph of the reaction as well as the rate law. Prove that the reaction is spontaneous and describe any factors that increase the reaction's entropy. Organize and present the information in a computer slide-show presentation. Use graphics to create interest in your reaction.

Math Tune-Up: Equilibrium Problems

Problem	❶ Analyze	❷ Calculate	❸ Evaluate
Gaseous sulfur dioxide reacts with oxygen in a 1.0-L container at 600°C to form gaseous sulfur trioxide. $2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$ At equilibrium, a mixture of these gases contains 1.5 mol SO_2, 1.2 mol O_2, and 3.4 mol SO_3. What is the equilibrium constant for this reaction?	Knowns: $[SO_2] = 1.5$ mol/L $[O_2] = 1.2$ mol/L $[SO_3] = 3.4$ mol/L Unknown: $K_{eq} = ?$ Use the expression for K_{eq}: $K_{eq} = \frac{[C]^c \times [D]^d}{[A]^a \times [B]^b}$	Write the expression for K_{eq} for this equation and substitute the equilibrium concentrations in the expression. $K_{eq} = \frac{[SO_3]^2}{[SO_2]^2 \times [O_2]}$ $= \frac{(3.4 \text{ mol/L})^2}{(1.5 \text{ mol/L})^2 \times (1.2 \text{ mol/L})}$ $K_{eq} = 4.3$	Each concentration is raised to the correct power. The value for K_{eq} is appropriate for an equilibrium mixture that contains a larger number of moles of products than of reactants.
What is the concentration of silver ions and chloride ions in a saturated solution of silver chloride at 25°C? ($K_{sp} = 1.8 \times 10^{-10}$)	Knowns: $K_{sp} = 1.8 \times 10^{-10}$ $AgCl(s) \rightleftharpoons Ag^+(aq) + Cl^-(aq)$ Unknowns: $[Ag^+] = ?M$ $[Cl^-] = ?M$ Use the expression for K_{sp}: $K_{sp} = [A]^a \times [B]^b$	Write the expression for K_{sp}, modify it so there is a single unknown, and solve for that unknown. $K_{sp} = [Ag^+] \times [Cl^-]$ $1.8 \times 10^{-10} = [Ag^+]^2$ $[Ag^+] = \sqrt{1.8 \times 10^{-10}}$ $[Ag^+] = 1.3 \times 10^{-5}M$ $[Cl^-] = 1.3 \times 10^{-5}M$	If you multiply $[Ag^+] \times [Cl^-]$, the result is 1.7×10^{-10}, which is close to the value of K_{sp}. The value is not exactly the same because the answers are rounded to two significant figures. Hint: At equilibrium, $[Ag^+] = [Cl^-]$.
Predict whether a precipitate will form when 0.50 L of 0.001M $Ca(NO_3)_2$ is mixed with 0.50 L of 0.0008M Na_2CO_3 to form one liter of solution. The K_{sp} of $CaCO_3$ is 4.5×10^{-9}.	Knowns: 0.50 L of 0.001M $Ca(NO_3)_2$ 0.50 L of 0.0008M Na_2CO_3 K_{sp} of $CaCO_3 = 4.5 \times 10^{-9}$ Unknown: $[Ca^{2+}] \times [CO_3^{2-}] > K_{sp}$? Precipitation will occur if the product of the concentrations of the two ions exceeds the K_{sp} value of $CaCO_3$.	Divide the initial concentrations in half because the volume of the solution has doubled. Multiply the concentrations together as a trial product and compare with K_{sp}. $[Ca^{2+}]$ (final) = 0.0005M $[CO_3^{2-}]$ (final) = 0.0004M $[Ca^{2+}] \times [CO_3^{2-}] = (0.0005M) \times (0.0004M) = 2 \times 10^{-7}$ $2 \times 10^{-7} > K_{sp}$, so a precipitate will form.	A precipitate will form in this case because 2.0×10^{-7} is greater than 4.5×10^{-9}. Remember: Equilibrium constants are not reported with units.

Focus on ELL

5 ASSESS UNDERSTANDING Practice for standardized tests by assigning students to complete the Standardized Test Prep for this chapter. Make sure students know how to correctly use the state-specific answer sheet. If students struggle with questions, suggest they review the material with a partner.

BEGINNING: LOW/HIGH Have students underline the high-frequency words they understand and use context clues to eliminate unlikely distracters.

INTERMEDIATE: LOW/HIGH Explain to students that they can skip a question they do not understand immediately. Tell students to mark that test question with a symbol so they remember to come back to it. Tell students to also skip the corresponding item number on the answer sheet.

ADVANCED: LOW/HIGH Have students write out each question they answered incorrectly because they did not understand the concept. Tell students to find the information they need and then try the question again.

Math Review

Example and sample practice problems for the various reaction rate and equilibrium problems can be found on the following pages:

LESSON 18.2 Finding the Order of a Reaction From Experimental Data—page 606

LESSON 18.3 Applying Le Châtelier's Principle—page 615; Expressing and Calculating K_{eq}—page 617; Finding the Equilibrium Constant—page 618; Finding Concentrations at Equilibrium—page 619

LESSON 18.4 Finding the Ion Concentrations in a Saturated Solution—page 623; Finding Equilibrium Ion Concentrations in the Presence of a Common Ion—page 625

ASSESSMENT

Evaluate

Answers

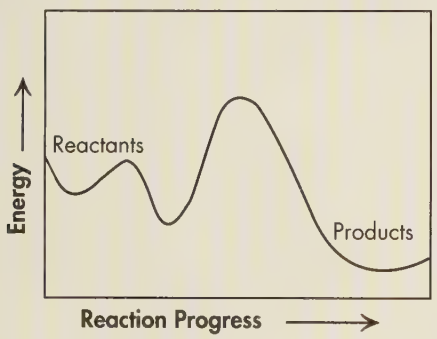
LESSON 18.1

54. Atoms, ions, or molecules can react to form products, or they can bounce apart unchanged.

55. the minimum energy that colliding particles must have in order to react

56. c

57. Gas molecules and oxygen molecules do not have enough energy to react at room temperature. The flame raises the temperature and the energy of collisions, so the reaction begins. The heat released by the reaction maintains the high temperature, and the reaction continues spontaneously.



58. A catalyst increases the rate of reactions by providing an alternative reaction mechanism with a lower activation energy.

LESSON 18.2

59. an expression of the rate of reaction in terms of concentrations of reactants

60. A first-order reaction has a reaction rate that is directly proportional to concentration of only one reactant. A higher-order reaction has a reaction rate that is dependent on the concentrations of more than one reactant.

61.

The intermediate is $N_2O_2(g)$.

62. $2NO(g) + O_2(g) \rightarrow 2NO_2(g)$

LESSON 18.3

63. In a reversible reaction, reactants are continually forming products and products are continually forming reactants.

64. They are equal.

65. It states that a system in dynamic equilibrium changes to relieve a stress applied to it.

66. **a.** $K_{eq} = \dfrac{[H_2S]^2 \times [CH_4]}{[H_2]^4 \times [CS_2]}$ **b.** $K_{eq} = \dfrac{[PCl_3] \times [Cl_2]}{[PCl_5]}$

67. **a.** highly favorable **b.** favorable **c.** highly unfavorable

68. c; If the pressure is increased, the equilibrium position will shift to left (reactant side) to relieve the stress by reducing the number of gas molecules.

18 Assessment

* Solutions appear in Appendix E

Lesson by Lesson

18.1 Rates of Reaction

***54.** According to collision theory, what are two things that can happen when atoms, ions, or molecules collide?

55. What is activation energy?

56. Which of these statements is true?

a. Chemical reactions tend to slow down when the temperature rises.

b. Once a chemical reaction starts, the reacting particles no longer have to collide for products to form.

c. Increasing the total surface area of solid or liquid reactants increases the rate of the reaction.

57. When the gas to a stove is turned on, the gas does not burn until it is lit by a flame. Explain this observation in terms of the effect of temperature on reaction rate.

***58.** Explain how a catalyst is able to change the rate of a reaction.

18.2 The Progress of Chemical Reactions

59. What is a rate law?

60. How is a first-order reaction different from higher-order reactions?

***61.** Sketch a reaction progress curve for the overall reaction with the following mechanism:

$$2NO(g) \longrightarrow N_2O_2(g) \text{ (fast)}$$

$$N_2O_2(g) + O_2(g) \longrightarrow 2NO_2(g) \text{ (slow)}$$

What is the intermediate in this reaction?

62. Write the balanced equation for the overall reaction described in Question 61.

18.3 Reversible Reactions and Equilibrium

63. In your own words, define a reversible reaction.

64. Compare the rates of the forward and reverse reactions when a chemical equilibrium has been established.

65. What is Le Châtelier's principle?

***66.** Write the expression for the equilibrium constant for each reaction.

a. $4H_2(g) + CS_2(g) \rightleftharpoons CH_4(g) + 2H_2S(g)$

b. $PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$

67. For each reaction, decide whether products or reactants will be more common at equilibrium.

a. $H_2(g) + F_2(g) \rightleftharpoons 2HF(g)$; $K_{eq} = 1 \times 10^{13}$

b. $SO_2(g) + NO_2(g) \rightleftharpoons NO(g) + SO_3(g)$; $K_{eq} = 1 \times 10^{2}$

c. $2H_2O(g) \rightleftharpoons 2H_2(g) + O_2(g)$; $K_{eq} = 6 \times 10^{-28}$

68. For which reaction will a change in pressure affect the equilibrium position? How will the position change, and why?

a. $H_2(g) + F_2(g) \longrightarrow 2HF(g)$

b. $SO_2(g) + NO_2(g) \longrightarrow NO(g) + SO_3(g)$

c. $2H_2O(g) \longrightarrow 2H_2(g) + O_2(g)$

18.4 Solubility Equilibrium

69. What does the solubility product constant (K_{sp}) represent?

70. Write the expression for K_{sp} for each of the following compounds:

a. NiS **b.** $BaCO_3$

***71.** Use Table 18.2 to rank these compounds from most soluble to least soluble.

a. CuS **b.** $BaSO_4$ **c.** $SrCO_3$ **d.** AgI

72. What happens when a common ion is added to a saturated solution of an ionic compound?

18.5 Free Energy and Entropy

73. Explain what it means to say that a process is 50 percent efficient.

74. Compare the amount of product at equilibrium in a spontaneous reaction to the amount of product at equilibrium in a nonspontaneous reaction.

75. State the law of disorder in your own words.

76. Which system in each example below has the lower entropy?

a. 50 mL of liquid water or 50 mL of ice

b. 10 g of sodium chloride crystals or a solution containing 10 g of sodium chloride

LESSON 18.4

69. the product of the ion concentrations raised to the power of their coefficients

70. **a.** $[Ni^{2+}][S^{2-}]$ **b.** $[Ba^{2+}][CO_3^{2-}]$

71. c, b, d, a

72. It lowers the solubility of the ionic compound.

LESSON 18.5

73. Only 50 percent of the free energy is actually used to do work.

74. The amount of product at equilibrium in a spontaneous reaction is much greater.

75. Systems naturally move toward maximum disorder.

76. **a.** ice b. sodium chloride crystals

*77. Does entropy increase or decrease in each of the following reactions:

a. $CaCO_3(s) \longrightarrow CaO(s) + CO_2(g)$

b. $NH_3(g) + HCl(g) \longrightarrow NH_4Cl(s)$

78. Is it true that all spontaneous processes are exothermic? Explain your answer.

79. Explain why steam condenses to liquid water at normal atmospheric pressure even though the entropy change is unfavorable. *Hint:* Is condensation exothermic or endothermic?

80. How can a change in Gibbs free energy be used to predict whether a reaction will be spontaneous?

Understand Concepts

*81. Which of the following statements are always true for a reaction that is spontaneous?

a. The reaction is exothermic.

b. Entropy is increased in the reaction.

c. Free energy is released in the reaction.

82. Use Le Châtelier's principle to explain why carbonated drinks go flat when their containers are left open.

83. Consider the decomposition of N_2O_5 in carbon tetrachloride (CCl_4) at 45°C.

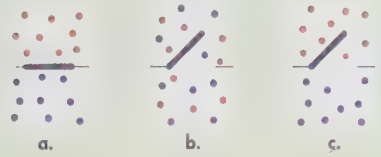
$$2N_2O_5(soln) \longrightarrow 4NO_2(g) + O_2(g)$$

The reaction is first order in N_2O_5, with the specific rate constant $6.08 \times 10^{-4}\ s^{-1}$. Calculate the reaction rate at these conditions.

a. $[N_2O_5] = 0.200$ mol/L

b. $[N_2O_5] = 0.319$ mol/L

84. Consider the following reversible reaction:



$$2NO_2(g) \rightleftharpoons N_2O_4(g)$$

What will happen to the reaction rate if the concentration of NO_2 is changed from 0.020 mol/L to 0.030 mol/L? What will happen to the equilibrium position?

*85. For the reaction A + B $\rightleftharpoons$ C, the activation energy of the forward reaction is 5 kJ, and the total energy change is −20 kJ. What is the activation energy of the reverse reaction?

86. Sketch a reaction progress curve for a reaction that has an activation energy of 22 kJ and a total energy change of −103 kJ.

87. A large box is divided into two compartments with a door between them. In (a), equal quantities of two different monatomic gases are placed in the two compartments. In (b), the door between the compartments is opened, and the gases start to mix. Why would it be highly unlikely for the system in (b) to progress to the system in (c)?

88. Would you expect the entropy to increase in each of the following reactions? Explain your reasoning.

a. $C(s) + O_2(g) \longrightarrow CO_2(g)$

b. $2Al_2O_3(s) \longrightarrow 4Al(s) + 3O_2(g)$

c. $2N(g) \longrightarrow N_2(g)$

d. $N_2(g) \longrightarrow 2N(g)$

*89. What would be the effect on the equilibrium position if the volume is decreased in the following reaction?

$$4HCl(g) + O_2(g) \rightleftharpoons 2Cl_2(g) + 2H_2O(g)$$

90. Write the equilibrium-constant expression for this reaction.

$$2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$$

*91. A mixture at equilibrium at 827°C contains 0.552 mol CO_2, 0.552 mol H_2, 0.448 mol CO, and 0.448 mol H_2O. The balanced equation is shown below.

$$CO_2(g) + H_2(g) \rightleftharpoons CO(g) + H_2O(g)$$

What is the value of K_{eq}?

*92. What must be true about the concentration of two ions if precipitation occurs when solutions of the two ions are mixed?

93. What is the concentration of carbonate ions in a saturated solution of $SrCO_3$? ($K_{sp} = 9.3 \times 10^{-10}$)

94. Predict what will happen to the rate of a slow reversible reaction if a catalyst is added. What will happen to the equilibrium position?

95. Make a list of five things you did today that resulted in an increase in entropy.

77 **a.** Entropy increases. **b.** Entropy decreases.

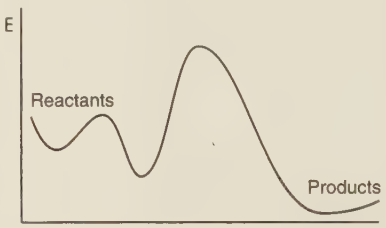
78. No, some endothermic processes are spontaneous because of their favorable change in entropy.

79. The favorable exothermic change of the condensation process offsets the unfavorable entropy change.

80. A spontaneous reaction has a negative free energy.

UNDERSTAND CONCEPTS

81. c



82. Carbonated drinks in closed containers are in a state of dynamic equilibrium between the CO_2 in the liquid and above the liquid. When the container is opened, CO_2 gas above the liquid escapes. The gas bubbles out of the liquid in an attempt to reestablish equilibrium.

83. **a.** 1.22 10^{-4} mol/(L•s) **b.** 1.94 10^{-4} mol/(L•s)

84. The rate will increase. The equilibrium position will shift to the right.

85. Since the total energy change for the forward reaction (−20 kJ) is negative, energy is released, and the reaction is exothermic. The reverse reaction is endothermic (energy is absorbed). The activation energy of the reverse reaction is the total height of the peak (20 kJ + 5 kJ = 25 kJ).

86.

87. The change from **a** to **b** is spontaneous, favored by an increase in entropy. The change from **b** to **c** will not occur, because it would result in a decrease in entropy, causing the process to be nonspontaneous.

88. **a.** yes; A solid becomes a gas.

b. yes; A single solid becomes two products, one of them a gas.

c. no; Two particles become one.

d. yes; One particle becomes two.

89. increase in products

90. $$K_{eq} = \frac{[C]^c \times [D]^d}{[A]^a \times [B]^b}$$

91. $K_{eq} = 6.59 \times 10^{-1}$

92. The product of the concentrations of the ions must be greater than the ion-product constant (K_{sp}).

93. $3.0 \times 10^{-5} M$

94. A catalyst will establish equilibrium more quickly, but it does not change the equilibrium position.

95. Possible answers: use a blow dryer, flush a toilet, mow the lawn, cook breakfast, drive a car, and breathing

ASSESSMENT

Evaluate

Answers

96. $2.0 \times 10^{-8} M$

97. **a.** favors products

b. no effect

c. favors reactants

d. no effect

98. Yes, the product of the concentration of the two ions (3.8×10^{-5}) is greater than the K_{sp} value for the compound (1.7×10^{-5}).

THINK CRITICALLY

99. A catalyst increases the efficiency of the collisions; more collisions result in the formation of the product.

100. **a.** IO^-

b. two

c. the slow reaction

d. $2H_2O_2 \rightarrow 2H_2O + O_2$

e. No, the I^- is changed in the reaction. A catalyst would not appear in the reaction as a reactant, an intermediate, or a product.

101. Increasing pressure tends to reduce volume and increase density, so the system responds by favoring production of liquid, which is denser.

102. **a.** Fanning brings more oxygen into contact with the campfire.

b. The ice cubes have a larger surface area than the block of ice, and thus interact more with the warmer surroundings.

c. MnO_2 is a catalyst; the reaction occurs explosively.

103. first order in NO_2^-, first order in NH_4^+, second order overall

104. The purpose of a speed bump is to hinder a driver from speeding in a particular area. The activation energy hinders reactants from being converted to products.

105. Increase pressure, cool the reaction mixture, and remove NH_3

106. The coefficients in the equation seldom correspond with the exponents in the rate law.

107. Lowering the temperature of the jam slows down the rates of the reactions that cause the jam to spoil.

96. What is the equilibrium concentration of barium ion in a 1.0-L saturated solution of barium carbonate to which 0.25 mol K_2CO_3 is added?

***97.** Suppose equilibrium is established for the following reaction at 425 K:

$$Fe_3O_4(s) + 4H_2(g) \rightleftharpoons 3Fe(s) + 4H_2O(g)$$

How would the equilibrium concentration of H_2O be affected by these actions?

a. adding more H_2 to the mixture

b. increasing the pressure

c. removing $H_2(g)$

d. adding a catalyst

98. A student prepares a solution by combining 0.025 mol $CaCl_2$ and 0.015 mol $Pb(NO_3)_2$ and adding water to make 1.0 L of solution. Will a precipitate of $PbCl_2$ form in this solution?

Think Critically

99. **Relate Cause and Effect** An increase in temperature raises the energy of the collisions between reactant molecules. An increase in the concentration of reactants increases the number of collisions. What is the effect of a catalyst on the collisions between molecules?

***100.** **Draw Conclusions** The mechanism for the decomposition of hydrogen peroxide is thought to be as follows:

$$H_2O_2(aq) + I^-(aq) \longrightarrow H_2O(l) + IO^-(aq) \text{ (slow)}$$

$$IO^-(aq) + H_2O_2(aq) \longrightarrow H_2O(l) + O_2(g) + I^-(aq) \text{ (fast)}$$

a. What is the intermediate?

b. What is the minimum number of activated complexes needed to describe the reaction?

c. Which of the two reactions has the smaller specific rate constant?

d. Write the overall balanced chemical equation for the reaction.

e. Does I^- qualify as a catalyst? Explain.

101. **Relate Cause and Effect** The freezing of liquid water at 0°C can be represented as follows.

$$H_2O(l) \rightleftharpoons H_2O(s)$$

The density of the liquid water is 1.00 g/cm^3. The density of the ice is 0.92 g/cm^3. Explain why applying pressure causes ice to melt.

102. **Apply Concepts** Explain what is happening in each of the following situations.

a. A campfire is "fanned" to help get it going.

b. Ice cubes melt faster than a block of ice with the same mass.

c. A pinch of powdered manganese dioxide causes hydrogen peroxide to explode even though the manganese dioxide is not changed.

***103.** **Analyze Data** Ammonium ions and nitrite ions react in water to form nitrogen gas.

$$NO_2^-(aq) + NH_4^+(aq) \longrightarrow N_2(g) + 2H_2O(l)$$

From the following data, decide the order of the reaction with respect to NH_4^+ and NO_2^- and the overall order of the reaction.

Initial $[NO_2^-]$ (mol/L)	Initial $[NH_4^+]$ (mol/L)	Initial rate (mol/(L·s))
0.0100	0.200	5.4×10^{-7}
0.0200	0.200	10.8×10^{-7}
0.0400	0.200	21.5×10^{-7}
0.0600	0.200	32.3×10^{-7}
0.200	0.0202	10.8×10^{-7}
0.200	0.0404	21.6×10^{-7}
0.200	0.0606	32.4×10^{-7}
0.200	0.0808	43.3×10^{-7}

104. **Use Analogies** A speed bump is a raised ridge that runs across the surface of a street, a parking lot, or driveway. What is the purpose of a speed bump, and how is it similar to activation energy?

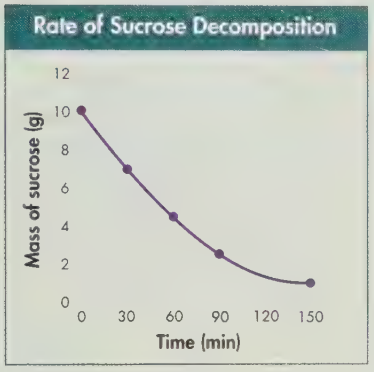
***105.** **Apply Concepts** In the reversible reaction for the formation of ammonia, the enthalpy change and the entropy change both favor the reverse reaction.

$$N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g) + \text{heat}$$

You are the chemical engineer in charge of the large-scale production of ammonia. What are three things you can do to increase the percent yield of your product?

106. **Compare and Contrast** When you calculate the K_{eq} for a reaction, you use the coefficient from the balanced equation. Why are the coefficients not used to find the order of a reaction?

107. **Infer** Jars of jam are stored on grocery shelves at room temperature. Why does the instruction "Refrigerate after opening" appear on the label?



Enrichment

108. Graph The following data were collected for the decomposition of compound AB into its elements. The reaction is first order in AB. Answer the following questions.

[AB] (mol/L)	Time (s)
0.300	0
0.246	50
0.201	100
0.165	150
0.135	200
0.111	250
0.090	300
0.075	350

a. Make a graph of concentration (y-axis) versus time (x-axis).
b. Determine the rate of the reaction at $t = 100$ seconds and $t = 250$ seconds.

***109. Interpret Graphs** When table sugar, or sucrose, is dissolved in an acid, the sucrose slowly decomposes into two simpler sugars: fructose and glucose. Use the graph to answer the following questions:

a. How many grams of sucrose decompose in the first 30 minutes?
b. How many grams of sucrose decompose in the interval between 90 minutes and 120 minutes?
c. In general, what happens to the rate of decomposition with time?

Write About Science

110. Explain Compost is a mixture that gardeners add to soil to improve the soil. Many gardeners make their own compost by recycling yard and kitchen waste. What types of reactions take place in a compost pile? Why is it important that the compost pile be turned regularly?

111. Connect to the BIGIDEA A discussion of reaction rates often focuses on ways to speed up reactions. However, sometimes it is important to know how to slow down a reaction, such as combustion. Use Le Châtelier's principle to explain why some of the methods that are used to fight fires work.

CHEMYSTERY

Explosive Sugar

The U.S. Chemical Safety Board (CSB) investigates chemical accidents in the workplace. The agency uses what it learns to recommend ways to improve safety. In 2009, the CSB issued a report on the explosion at the sugar refinery in Georgia.

A year before the blast, a steel cover was added to the conveyor belt where the first explosion took place. The cover was added to keep the sugar clean. But the cover also allowed dangerous concentrations of sugar dust to build up around the belt. It was difficult for the CSB to pinpoint the exact cause of the first explosion because of the amount of damage. However, they suspected that an overheated part of the belt ignited the dust.

Vibrations from the small explosion shook loose sugar dust that had collected on many surfaces in the warehouse. Suddenly the air inside the warehouse was filled with tiny particles of sugar.

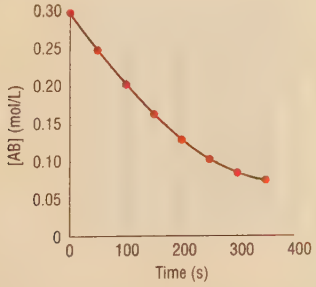
112. Relate Cause and Effect Explain how the first explosion increased the likelihood that a second, more violent explosion would occur?

113. Connect to the BIGIDEA Suppose you worked for the CSB. What recommendations would you make to prevent similar fires in the future?

ASSESSMENT

CHEMYSTERY **SUMMARIZE** Have students read over the CHEMystery. Then have volunteers produce a flow chart on the board to summarize the events at the sugar refinery and relate this to what they have learned about concentration and chemical reactions. **Ask** What would happen to the concentration of sugar dust in the air when the first small explosion shook the warehouse? *(The concentration would increase.)* How do you think the increase in concentration would affect the likelihood of larger explosion? Why? *(The likelihood of a larger explosion would increase because the particles of sugar are more likely to touch an overheated surface in the warehouse and ignite.)*

CHEMYSTERY ANSWERS



112. The first explosion produced vibrations that shook surfaces in the warehouse. Sugar dust on these surfaces was thrown upward, resulting in a high concentration of sugar dust in the air. The high concentration of sugar dust increased the likelihood that particles of sugar would touch an overheated surface and ignite.

113 **BIGIDEA** Sample answer: To reduce the chance of an explosion, the concentration of sugar dust in the air must be kept low. I would recommend that the sugar refinery frequently clean the sugar dust from all surfaces.

Answers

ENRICHMENT

108.a.

b. The rate when $t = 100$ seconds is 8×10^{-4} mol/(L•s). The rate when $t = 250$ seconds is 4×10^{-4} mol/(L•s).

109.a. about 3 g
b. about 1.3 g
c. The rate of decomposition slows down over time.

WRITE ABOUT SCIENCE

110. decomposition reactions; Most decomposition reactions require energy, in this case, in the forms of heat and light.

111. **BIGIDEA** The main products of a combustion reaction are water and carbon dioxide. If one of these products is supplied to the fire, the combustion reaction will shift toward the reactants and cause the fire to slow or stop. (Some fire extinguishers contain pressurized carbon dioxide gas.)

a. Cl **c.** P **e.** Cu **g.** K
b. Ca **d.** Se **f.** Sn **h.** Fe

119. Find the mass in grams of each quantity.

a. 4.50 mol Fe
b. 36.8 L CO (at STP)
c. 1 molecule of glucose, $C_6H_{12}O_6$
d. 0.0642 mol ammonium phosphate

120. Aqueous silver nitrate reacts with aqueous potassium iodide to form the precipitate silver iodide.

a. Write the complete ionic equation.
b. What are the spectator ions?
c. Write the net ionic equation.

***121.** When heated, potassium chlorate decomposes into potassium chloride and oxygen gas.

a. Write the balanced equation for this chemical reaction.
b. How many grams of oxygen are formed when 4.88 g $KClO_3$ decompose?

122. Give the names and abbreviations of three units of pressure.

123. Is the boiling point of a liquid substance a constant? Explain.

124. What happens to the pressure of a contained gas in each instance?

a. More gas particles are added.
b. The temperature of the gas is decreased.
c. The volume of the container is reduced.

125. What volume will 24.5 g of carbon dioxide gas occupy at 55°C and a pressure of 88.8 kPa?

126. Which of these compounds should readily dissolve in water?

a. $KI(s)$ **c.** $NH_4Cl(s)$
b. $C_2H_6(g)$ **d.** $Na_3PO_4(s)$

127. Calculate the percent by mass of water in barium bromide tetrahydrate.

128. For which of these substances would the solubility in water be most likely to decrease with an increase in temperature?

a. $NH_4NO_3(s)$ **c.** $KI(s)$
b. $NH_3(g)$ **d.** $NaCl(s)$

***129.** How many moles of solute are in 2.40 L of 0.66*M* KCl?

130. How many liters of a stock solution of 6.00*M* HCl would you need to prepare 15.0 L of 0.500*M* HCl?

131. A small amount of ethanol (C_2H_5OH) is dissolved in a large beaker of water.

a. Identify the solute and the solvent.
b. Is the freezing point of the solution above or below 0°C?

132. How much heat is released when 12.4 g of steam at 100°C condenses to water at 100°C?

***133.** When solid sodium hydroxide is dissolved in water, the temperature of the solution rises. Is this an exothermic or endothermic process? Explain your answer.

134. The following is the equation for the complete combustion of ethene:

$$C_2H_4(g) + 3O_2(g) \longrightarrow 2CO_2(g) + 2H_2O(g) \qquad \Delta H = -1411 \text{ kJ}$$

How many kilojoules of heat are released when 32.8 g of ethene are burned?

132. -2.80×10^1 kJ

133. The process is exothermic because heat is released.

134. -1.65×10^3 kJ

Standardized Test Prep for Indiana

Select the choice that best answers each question or completes each statement.

1. Which reaction is represented by the following expression for an equilibrium constant?

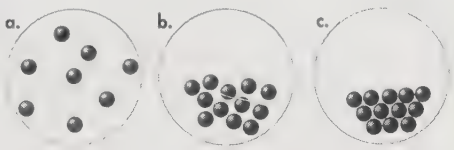
$$K_{eq} = \frac{[CO]^2 \times [O_2]}{[CO_2]^2}$$

(A) $2CO_2 \rightleftharpoons O_2 + 2CO$
(B) $CO_2{}^2 \rightleftharpoons O_2 + 2CO^2$
(C) $O_2 + 2CO \rightleftharpoons 2CO_2$
(D) $O_2 + CO_2 \rightleftharpoons CO_2{}^2$

2. At 25°C, zinc sulfide has a K_{sp} of 3.0×10^{-23}, zinc carbonate has a K_{sp} of 1.0×10^{-10}, and silver iodide has a K_{sp} of 8.3×10^{-17}. Order these salts from most soluble to least soluble.
(A) zinc carbonate, zinc sulfide, silver iodide
(B) silver iodide, zinc carbonate, zinc sulfide
(C) zinc carbonate, silver iodide, zinc sulfide
(D) zinc sulfide, silver iodide, zinc carbonate

Tips for Success

Multiple Parts Sometimes two phrases in a true/false question are connected with a word such as *because, therefore,* or *so.* These words imply a cause-and-effect relationship between the two phrases. Be aware that the overall statement can be false even if each phrase is true on its own.



Use the table to answer Questions 3 and 4.

ΔS	ΔH	ΔG	Spontaneous?
+	–	(a)	Yes
+	(b)	+ or –	At high T
(c)	+	+	No
–	–	(d)	At low T

3. The value of ΔG depends on the enthalpy (ΔH) and entropy (ΔS) terms for a reaction. The value of ΔG also varies as a function of temperature. Use the data in the table to identify the missing entries (a), (b), (c), and (d).

4. Which of these reactions would you expect to be spontaneous at relatively low temperatures? At relatively high temperatures?
(A) $H_2O(l) \longrightarrow H_2O(g)$
(B) $H_2O(g) \longrightarrow H_2O(l)$
(C) $H_2O(s) \longrightarrow H_2O(l)$

5. The atomic windows below represent different degrees of entropy. Arrange the windows in order of increasing entropy.

For each question below there are two statements. Decide whether each statement is true or false. Then decide whether Statement II is a correct explanation for Statement I.

	Statement I		Statement II
6.	A catalyst lowers the activation energy for a chemical reaction.	BECAUSE	A catalyst makes a reaction more exothermic.
7.	The entropy of ice is greater than the entropy of steam.	BECAUSE	The density of ice is greater than the density of steam.
8.	The rate of a chemical reaction is affected by a change in temperature.	BECAUSE	The kinetic energy of particles is related to the temperature.
9.	A large value for an equilibrium constant indicates that products are favored at equilibrium.	BECAUSE	The ratio of products to reactants at equilibrium is always > 1.

Materials List

For the Student

Quick Lab, p 662
- See SE p 662.

Small-Scale Lab, p 670
- reaction surface
- metric ruler
- pH buffer
- 0.04% solutions of BCG, BTB, BPB, MCP, and TB
- 0.05% MO, 0.02% AYR, 0.1% phenolphthalein

For the Teacher

Teacher Demo, p 647
- 5–10 mL of 1M HCl
- test tube
- small pieces of zinc
- safety match

Teacher Demo, p 658
- lemon juice
- tea
- antacid tablets
- glass of 10% grape juice
- household ammonia

Class Activity, p 659
- several test tubes
- 0.1M HCl 0.1M NaOH

Standard 8: Acids and Bases

C.8.1 Use Arrhenius and Bronsted-Lowry models to classify substances as acids or bases.

C.8.2 Describe the properties of acids and bases.

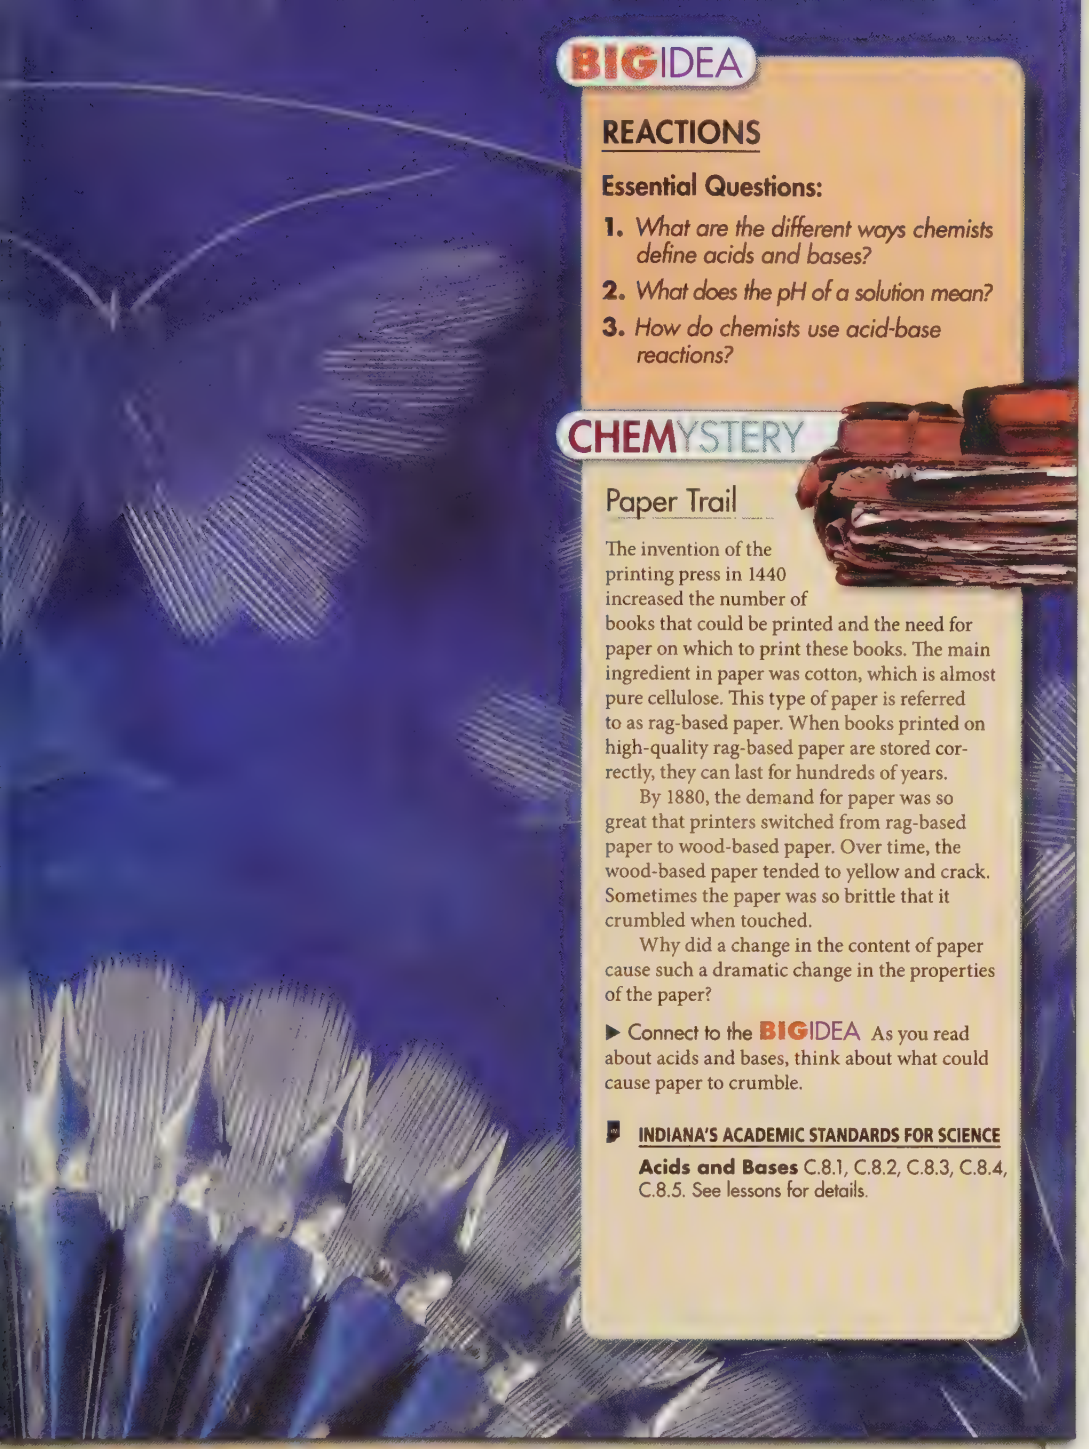
Also covered C.8.3, C.8.4, C.8.5

Focus on ELL

1 CONTENT AND LANGUAGE Make a three-column chart on the board, with the following headings: *Acids*, *Bases*, *Salts*. Have students, as a class, list what they know about each word. Have students identify any unfamiliar words in the lesson titles. Add these words to the classroom word wall.

BEGINNING:

LOW Make a nonlinguistic representation of each unfamiliar word.



HIGH Ask student volunteers to present *acid*, *base*, and *salt*. Have each one write a word on the board and introduce it to the class by pointing at it and saying it aloud.

INTERMEDIATE: LOW/HIGH Have students brainstorm and write examples of *acids, bases, and salts.*

ADVANCED:

LOW Write the definition of the each word and present it to the class.

HIGH Have students use context clues to predict the meanings of unfamiliar words.

BIGIDEA

REACTIONS

Essential Questions:

1. *What are the different ways chemists define acids and bases?*
2. *What does the pH of a solution mean?*
3. *How do chemists use acid-base reactions?*

CHEMYSTERY

Paper Trail

The invention of the printing press in 1440 increased the number of books that could be printed and the need for paper on which to print these books. The main ingredient in paper was cotton, which is almost pure cellulose. This type of paper is referred to as rag-based paper. When books printed on high-quality rag-based paper are stored correctly, they can last for hundreds of years.

By 1880, the demand for paper was so great that printers switched from rag-based paper to wood-based paper. Over time, the wood-based paper tended to yellow and crack. Sometimes the paper was so brittle that it crumbled when touched.

Why did a change in the content of paper cause such a dramatic change in the properties of the paper?

▶ Connect to the BIGIDEA As you read about acids and bases, think about what could cause paper to crumble.

INDIANA'S ACADEMIC STANDARDS FOR SCIENCE

Acids and Bases C.8.1, C.8.2, C.8.3, C.8.4, C.8.5. See lessons for details.

Introduce the Chapter

IDENTIFY PRECONCEPTIONS Students may believe that all acids are strong and highly caustic. Use the following activity to help them understand that some familiar foods contain acids that are not harmful.

Activity *You will need baking soda, cola, vinegar, lemon juice, small paper cups, and plastic spoons.* **Ask** What happens if you touch an acid? *(Students may say that acids will burn you.)* Explain that baking soda reacts with acids. Have students place a spoonful of baking soda into a cup. Then have them pour a few spoonfuls of cola into the cup and watch the reaction. Repeat with vinegar and lemon juice. Explain that strong acids are harmful, but cola, vinegar, and lemon juice all contain acids that are weak enough to ingest.

UbD

Understanding by Design

Students are building toward understanding chemical reactions by using knowledge of acids, bases, and salts.

PERFORMANCE GOALS At the end of Chapter 19, students will be able to answer the essential questions by applying their knowledge of acids, bases, and salts. Students will also be able to calculate pH and dissociation constants.

ESSENTIAL QUESTIONS Read the essential questions aloud. **Ask** What do you think are some properties of acids? *(Sample answer: They can burn or corrode materials.)* **Ask** What do you think it means when a television commercial advertises that an antacid tablet can "neutralize" stomach acid? *(Sample answer: The tablet can change the acid so that it is no longer harmful.)*

BIGIDEA Use the photo of etched glass to help students connect to the concepts they will learn in this chapter. Activate prior knowledge by explaining that pH is a measure of acidity and having students name ways they have heard about acids or pH in everyday life. *(Sample answers: acid rain, aquarium or pool water pH)* Draw students' attention to the photo. **Ask** What caused parts of the glass to change from clear to frosted? *(Acid reacted with the glass surface.)* Engage students in a discussion of how acids react in the examples they gave.

CHEMYSTERY Have students read over the CHEMystery. Connect the CHEMystery to the Big Idea of Reactions by pointing out that even though both cotton- and wood-based papers contain cellulose, the cotton-based paper does not break down as easily as the wood-based paper does. Have them consider what differences between the paper types might cause the wood-based paper to deteriorate more rapidly.

LESSON 19.1

Key Objectives

- **19.1.1 DEFINE** an acid and a base according to Arrhenius.
- **19.1.2 DISTINGUISH** an acid from a base in the Brønsted-Lowry theory.
- **19.1.3 DEFINE** an acid and a base according to Lewis.

C.8.2 Describe the characteristic properties of acids and bases.

19.1 Acid-Base Theories

C.8.1 Arrhenius and Bronsted-Lowry; C.8.2 Properties of acids and bases.

CHEMISTRY & YOU

Q: *Why are high levels of ammonia harmful to you?* Bracken Cave, near San Antonio, Texas, is home to millions of Mexican free-tailed bats. Nitrogen compounds in bat urine can decompose and release ammonia into the air. Visitors to the cave must wear protective goggles and respirators. They need this protection because of what happens when ammonia reacts with water. Ammonia is an example of a base. In this lesson, you will learn about some of the properties of acids and bases.

Key Questions

- ***How did Arrhenius define an acid and a base?***
- ***What distinguishes an acid from a base in the Brønsted-Lowry theory?***
- ***How did Lewis define an acid and a base?***

Vocabulary

- hydronium ion (H_3O^+)
- conjugate acid
- conjugate base
- conjugate acid-base pair
- amphoteric
- Lewis acid
- Lewis base

Arrhenius Acids and Bases

How did Arrhenius define an acid and a base?

Acids and bases have distinctive properties. Many of the foods you eat, including those shown in Figure 19.1a, contain acids. Acids give foods a tart or sour taste. Lemons, which taste sour enough to make your mouth pucker, contain citric acid. Aqueous solutions of acids are strong or weak electrolytes. Recall that an electrolyte can conduct electricity. The electrolyte in a car battery is an acid. Acids cause certain chemical dyes, called indicators, to change color. Many metals, such as zinc and magnesium, react with aqueous solutions of acids to produce hydrogen gas.

The soap in Figure 19.1b is a familiar material that has the properties of a base. If you have accidentally tasted soap, you know that it has a bitter taste. This bitter taste is a general property of bases, but one that is dangerous to test. The slippery feel of soap is another property of bases. Like acids, bases will cause an indicator to change color. Bases also form aqueous solutions that are strong or weak electrolytes.

Chemists had known the properties of acids and bases for many years. Yet they were not able to propose a theory to explain this behavior. Then, in 1887, the Swedish chemist Svante Arrhenius proposed a new way of defining and thinking about acids and bases. **According to Arrhenius, acids are hydrogen-containing compounds that ionize to yield hydrogen ions (H^+) in aqueous solution. Bases are compounds that ionize to yield hydroxide ions (OH^-) in aqueous solution.**

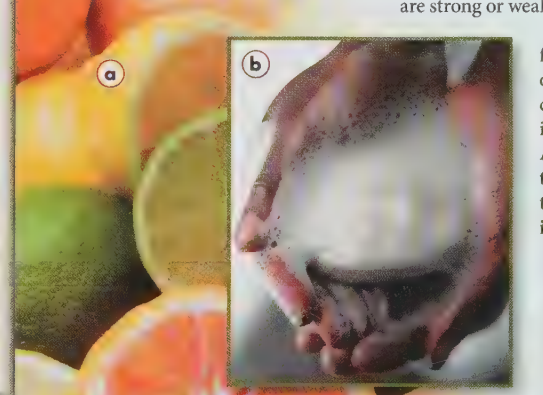

Figure 19.1 Acids and Bases
Many items contain acids or bases, or produce acids and bases when dissolved in water. **a.** Citrus fruits contain citric acid ($HC_6H_7O_7$). **b.** Many soaps are made using the common base sodium hydroxide (NaOH).

Focus on ELL

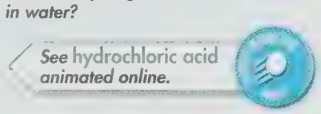
1 CONTENT AND LANGUAGE Read aloud each key question, making sure to enunciate each word. Have students repeat the three theory names. Define the term *distinguish*, and then ask students to rely on this definition to orally paraphrase the key questions.

2 FRONTLOAD THE LESSON Write the term *battery acid* on the board, and ask volunteers to explain why acids are used to make batteries. *(They conduct electricity.)* Remind students that chemical compounds that conduct electricity when in aqueous solution are called *electrolytes*. Have students review what they know about the behavior of electrolytes in solution.

3 COMPREHENSIBLE INPUT Copy Table 19.1 on the board. Add a column labeled *Equations*. Write chemical equations to show the behavior of acids in solution and demonstrate the multiple dissociations possible for polyprotic acids.

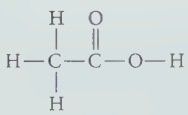
Arrhenius Acids Table 19.1 lists six common acids. They vary in the number of hydrogens they contain that can form hydrogen ions. A hydrogen atom that can form a hydrogen ion is described as *ionizable*. Nitric acid (HNO_3) has one ionizable hydrogen, so nitric acid is classified as a *monoprotic* acid. The prefix *mono-* means "one," and the stem *protic* reflects the fact that a hydrogen ion is a proton. Acids that contain two ionizable hydrogens, such as sulfuric acid (H_2SO_4), are called *diprotic* acids. Acids that contain three ionizable hydrogens, such as phosphoric acid (H_3PO_4), are called *triprotic* acids.

Not all compounds that contain hydrogen are acids. Also, some hydrogens in an acid may not form hydrogen ions. Only a hydrogen that is bonded to a very electronegative element can be released as an ion. Recall that such bonds are highly polar. When a compound that contains such bonds dissolves in water, it releases hydrogen ions. An example is the hydrogen chloride molecule, shown below.



$$\overset{\delta+}{H}\text{—}\overset{\delta-}{Cl}(g) \xrightarrow{H_2O} H^+(aq) + Cl^-(aq)$$

Hydrogen chloride → Hydrogen ion + Chloride ion (hydrochloric acid)



However, in an aqueous solution, hydrogen ions are not present. Instead, the hydrogen ions are joined to water molecules as hydronium ions. A **hydronium ion (H_3O^+)** is the ion that forms when a water molecule gains a hydrogen ion. As seen in Figure 19.2, hydrogen chloride ionizes to form an aqueous solution of hydronium ions and chloride ions.

Figure 19.2 Hydrochloric Acid
Hydrochloric acid is actually an aqueous solution of hydrogen chloride. Hydrogen chloride forms hydronium ions, making this compound an acid.
Explain ***Why does hydrogen chloride release a hydrogen ion when dissolved in water?***

In contrast to hydrogen chloride, methane (CH_4) is an example of a hydrogen-containing compound that is not an acid. The four hydrogen atoms in methane are attached to the central carbon atom by weakly polar C—H bonds. Thus, methane has no ionizable hydrogens and is not an acid. Ethanoic acid (CH_3COOH), which is commonly called acetic acid, is an example of a molecule that contains both hydrogens that do not ionize and a hydrogen that does ionize. Although its molecules contain four hydrogens, ethanoic acid is a monoprotic acid. The structural formula shows why.

Ethanoic acid (CH_3COOH)

The three hydrogens attached to a carbon atom are in weakly polar bonds. They do not ionize. Only the hydrogen bonded to the highly electronegative oxygen can be ionized. For complex acids, you need to look at the structural formula to recognize which hydrogens can be ionized.

Table 19.1
Some Common Acids

Name	Formula
Hydrochloric acid	HCl
Nitric acid	HNO_3
Sulfuric acid	H_2SO_4
Phosphoric acid	H_3PO_4
Ethanoic acid	CH_3COOH
Carbonic acid	H_2CO_3

Professional Development Note

Acetic Acid

Acetic acid is the common name for ethanoic acid, the acid found in vinegar. The word *acetic* comes from the Latin word *acetum*, meaning "vinegar." This word origin is fitting because early vinegars were products of the souring of wine. Wines sour due to the activity of *Acetobacter* bacteria, which convert ethanol into ethanoic acid. This genus of bacteria is especially resistant to high concentrations of both ethanol and ethanoic acid, making it unusual in the bacterial world. Early wine vinegars developed as the result of natural contamination by these bacteria, which are plentiful in water and soil as well as on crops and fruit. Ethanoic acid intended for human consumption is still made using bacterial fermentation, but industrial ethanoic acid is usually produced by reacting carbon monoxide with methanol in the presence of a catalyst such as hydrogen iodide.

Foundations for Reading

BUILD VOCABULARY Explain that one definition of the word *conjugate* is "having features in common but opposite or inverse in some particular." Have students keep this definition in mind as they read the lesson.

READING STRATEGY Have students preview the lesson. Then have them create a compare- and-contrast table to differentiate between the three acid-base theories.

Explain

Arrhenius Acids and Bases

USE AN ANALOGY Explain that in this lesson students will be exposed to three different ways in which an acid or base is defined. Help students to understand that the definitions presented are all correct, but some definitions include more possible substances. Explain that where one definition lacks, another fills in. Relate the lesson content to a coaching strategy or a gaming strategy, in which there may be more than one possible correct play or solution that leads to victory, even though some plays or solutions may provide more avenues to success than others.

USE VISUALS Direct students' attention to Table 19.1. Note that the acids in the table are listed in order of decreasing tendency to yield hydrogen ions. **Ask** What element do all the acids in this table have in common? *(hydrogen)*

Explore

Properties of Acids and Bases

PURPOSE Demonstrate that many metals and acids react to produce hydrogen gas.

MATERIALS 5–10 mL of 1*M* HCl, test tube, small pieces of zinc, match

SAFETY Wear safety goggles, gloves, and a lab apron while performing the demonstration.

PROCEDURE Add 5–10 mL 1*M* HCl to a test tube and add a few small pieces of zinc metal.

EXPECTED OUTCOME Gas bubbles are liberated from the solution. Explain that many metals react with aqueous acids to produce hydrogen gas. Remind students that hydrogen is a highly flammable gas. Demonstrate the liberation of the gas by placing a lit match at the mouth of the test tube to ignite the hydrogen.

Explain

USE VISUALS Have students study Table 19.2. Have them note that the bases containing Group 1 elements appear to be highly soluble in water, while those containing Group 2 elements are not. **Ask** Based on this generalization, is LiOH likely or not likely to be soluble in water? *(LiOH is likely to be soluble in water.)* Explain that hydroxides of Group 2 elements increase in solubility going down the periodic table column. **Ask** Do you think $Be(OH)_2$ is soluble in water? *(insoluble)* $Sr(OH)_2$? *(quite soluble)*

Extend

Explain that acid–base concepts have been a part of chemistry for more than 300 years. Convey that over time, explanations were developed to explain the observed behavior of acids and bases. Point out that Arrhenius's explanation addresses compounds whose formulas contain obvious clues to their acidic or basic nature. Guide a student-led class discussion about the pros and cons of Arrhenius's explanation.

CHEMISTRY & YOU *Sample answer:* Ammonia can react with water in the eyes and air passages to form a corrosive solution.

Figure 19.3 Clogged Drains
Sometimes water backs up in a sink because the drain is clogged. A plumber can take apart the pipes to remove a clog, or a drain cleaner containing sodium hydroxide can be used to eat away the clog.

CHEMISTRY & YOU

Q: *Visitors to Bracken Cave wear protective gear to keep ammonia gas out of their eyes and respiratory tracts. Think about the properties of bases. Why are high levels of ammonia harmful?*

Table 19.2

Some Common Bases

Name	Formula	Solubility in water
Sodium hydroxide	NaOH	High
Potassium hydroxide	KOH	High
Calcium hydroxide	$Ca(OH)_2$	Very low
Magnesium hydroxide	$Mg(OH)_2$	Very low

Arrhenius Bases Table 19.2 lists four common bases. You may be familiar with the base sodium hydroxide (NaOH), which is also known as lye. Sodium hydroxide is an ionic solid. It dissociates into sodium ions and hydroxide ions in aqueous solution.

$$\underset{\text{Sodium hydroxide}}{NaOH(s)} \xrightarrow{H_2O} \underset{\text{Sodium ion}}{Na^+(aq)} + \underset{\text{Hydroxide ion}}{OH^-(aq)}$$

Sodium hydroxide is extremely caustic. A caustic substance can burn or eat away materials with which it comes in contact. This property is the reason that sodium hydroxide is a major component of products that are used to clean clogged drains. Figure 19.3 shows a drain cleaner that contains sodium hydroxide.

Potassium hydroxide (KOH) is another ionic solid. It dissociates to produce potassium ions and hydroxide ions in aqueous solution.

$$\underset{\text{Potassium hydroxide}}{KOH(s)} \xrightarrow{H_2O} \underset{\text{Potassium ion}}{K^+(aq)} + \underset{\text{Hydroxide ion}}{OH^-(aq)}$$

Sodium and potassium are Group 1A elements. Elements in Group 1A, the alkali metals, react violently with water. The products of these reactions are aqueous solutions of a hydroxide and hydrogen gas. The following equation summarizes the reaction of sodium with water.

$$\underset{\text{Sodium metal}}{2Na(s)} + \underset{\text{Water}}{2H_2O(l)} \longrightarrow \underset{\text{Sodium hydroxide}}{2NaOH(aq)} + \underset{\text{Hydrogen}}{H_2(g)}$$

Sodium hydroxide and potassium hydroxide are very soluble in water. Thus, making concentrated solutions of these compounds is easy. The solutions would have the typically bitter taste and slippery feel of a base. However, these are not properties that you would want to confirm. The solutions are extremely caustic to the skin. They can cause deep, painful, slow-healing wounds if not immediately washed off.

Differentiated Instruction

L3 ADVANCED STUDENTS Have students research the effect of electronegativity on the ease with which an acid releases its hydrogen ions. Then, have students use this information to demonstrate numerically why the acids at the top of Table 19.1 give up their hydrogen ions more easily than do those at the bottom of the table.

ELL ENGLISH LANGUAGE LEARNERS Have students create a list of all the words used to describe ion transfer, such as *donate*, *donor*, *accept*, *acceptor*, *loses*, *gains*. Have students look up the definition of each word and write the words and definitions in their vocabulary notebooks. Add the words to the word wall.

L1 STRUGGLING STUDENTS Have students copy all the tables in the lesson on one page in their notebooks. Have students examine the tables, looking for similarities and differences. Then have them re-create tables on a separate page that will help them to remember the important concepts.

Calcium hydroxide, $Ca(OH)_2$, and magnesium hydroxide, $Mg(OH)_2$, are compounds of Group 2A metals. These compounds are not very soluble in water. Their solutions are always very dilute, even when saturated. A saturated solution of calcium hydroxide has only 0.165 g $Ca(OH)_2$ per 100 g of water. Magnesium hydroxide is even less soluble than calcium hydroxide. A saturated solution has only 0.0009 g $Mg(OH)_2$ per 100 g of water. Figure 19.4 shows a suspension of magnesium hydroxide in water. Some people use this suspension as an antacid and as a mild laxative.

Brønsted-Lowry Acids and Bases

What distinguishes an acid from a base in the Brønsted-Lowry theory?

The Arrhenius definition of acids and bases is not a very broad one. It excludes some substances that have acidic or basic properties, on their own or in solution. For example, sodium carbonate (Na_2CO_3) and ammonia (NH_3) act as bases when they form aqueous solutions. Yet neither of these compounds is a hydroxide-containing compound, so neither compound would be classified as a base by the Arrhenius definition.

In 1923, the Danish chemist Johannes Brønsted and the English chemist Thomas Lowry were working independently. Each chemist proposed the same definition of acids and bases. **According to the Brønsted-Lowry theory, an acid is a hydrogen-ion donor and a base is a hydrogen-ion acceptor.** This theory includes all the acids and bases that Arrhenius defined. It also includes some compounds that Arrhenius did not classify as bases.

You can use the Brønsted-Lowry theory to understand why ammonia is a base. Ammonia gas is very soluble in water. When ammonia dissolves in water, hydrogen ions are transferred from water to ammonia to form ammonium ions and hydroxide ions.

$$NH_3(aq) + H_2O(l) \rightleftharpoons NH_4^+(aq) + OH^-(aq)$$

Figure 19.5 illustrates how each water molecule donates a hydrogen ion to ammonia. Ammonia is a Brønsted-Lowry base because it accepts hydrogen ions. Water is a Brønsted-Lowry acid because it donates hydrogen ions.

Figure 19.4 Milk of Magnesia
This product is a suspension of magnesium hydroxide in water. Most bases are too caustic to be swallowed. But, the low solubility of magnesium hydroxide makes the suspension safe to consume.

See ammonia in water animated online.

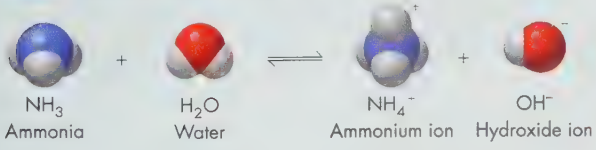


Figure 19.5
Ammonia in Water
When ammonia and water react, water molecules donate hydrogen ions to ammonia molecules. The reaction produces ammonium ions and hydroxide ions.
Explain ***Why is ammonia not classified as an Arrhenius base?***

UbD Check for Understanding

What properties are used to classify acids and bases?

Write the following list of properties on the board and have students classify each as a property of an acid, a base, or both: bitter taste, reacts with metals to form hydrogen gas, forms electrolytes in aqueous solution, sour taste, slippery feel. *(bitter taste, base; reacts with metals to form hydrogen gas, acid; forms electrolytes in aqueous solution, both; sour taste, acid; slippery feel, base)*

ADJUST INSTRUCTION If students are having difficulty answering, have them reread the first two paragraphs of the Arrhenius Acids and Bases section. Then allow them to revise their answers as appropriate.

Explain

Brønsted-Lowry Acids and Bases

APPLY CONCEPTS Explain that Brønsted arrived at his theory of acids and bases through his work in kinetics and thermodynamics. Point out that Brønsted noticed that a great many compounds that would not be classified as acids and bases by the Arrhenius definition behaved like acids and bases in his experiments. He found that these compounds were capable of hydrogen-ion transfer reactions. This led him to define acids as hydrogen-ion donors and bases as hydrogen-ion acceptors.

Misconception Alert

Some students may think the conjugate base of an acid in a given reaction appears on the same side of the equation as the acid. Explain that an acid does not react with its conjugate base but instead produces it or is produced by it in a reaction.

Answers

FIGURE 19.2 In HCl, hydrogen is bonded to a highly electronegative element.

FIGURE 19.5 Ammonia is not a hydroxide.

Explain

Brønsted-Lowry Acids and Bases

USE VISUALS Direct students' attention to Table 19.3. Have students study the Brønsted-Lowry acid-base conjugate pairs. **Ask** How are hydrogen ions related to Brønsted-Lowry acids? *(Acids lose hydrogen ions.)* **Ask** How are hydrogen ions related to Brønsted-Lowry bases? *(Bases gain hydrogen ions.)*.

Extend

Have students locate the two substances in Table 19.3 that are amphoteric. *(HSO_4^- and HCO_3^-)* Then, have them write reactions demonstrating each substance's role as an acid and as a base.

Conjugate Acids and Bases All gases become less soluble in water as the temperature rises. Thus, when the temperature of an aqueous solution of ammonia is increased, ammonia gas is released. This release acts as a stress on the system. In response to this stress, NH_4^+ reacts with OH^- to form more NH_3 and H_2O. In the reverse reaction, ammonium ions donate hydrogen ions to hydroxide ions. Thus, NH_4^+ (the donor) acts as a Brønsted-Lowry acid, and OH^- (the acceptor) acts as a Brønsted-Lowry base. In essence, the reversible reaction of ammonia and water has two acids and two bases.

$$\underset{\text{Base}}{NH_3(aq)} + \underset{\text{Acid}}{H_2O(l)} \rightleftharpoons \underset{\text{Conjugate acid}}{NH_4^+(aq)} + \underset{\text{Conjugate base}}{OH^-(aq)}$$

In the equation, the products of the forward reaction are distinguished from the reactants by the use of the adjective *conjugate*. This term comes from a Latin word meaning "to join together." A **conjugate acid** is the ion or molecule formed when a base gains a hydrogen ion. In the reaction above, NH_4^+ is the conjugate acid of the base NH_3. A **conjugate base** is the ion or molecule that remains after an acid loses a hydrogen ion. In the reaction above, OH^- is the conjugate base of the acid H_2O.

Conjugate acids are always paired with a base, and conjugate bases are always paired with an acid. A **conjugate acid-base pair** consists of two ions or molecules related by the loss or gain of one hydrogen ion. The ammonia molecule and the ammonium ion are a conjugate acid-base pair. The water molecule and the hydroxide ion are also a conjugate acid-base pair.

$$\underset{\text{Base}}{NH_3(aq)} + \underset{\text{Acid}}{H_2O(l)} \rightleftharpoons \underset{\text{Conjugate acid}}{NH_4^+(aq)} + \underset{\text{Conjugate base}}{OH^-(aq)}$$

The dissociation of hydrogen chloride in water provides another example of conjugate acids and bases.

$$\underset{\text{Acid}}{HCl(g)} + \underset{\text{Base}}{H_2O(l)} \rightleftharpoons \underset{\text{Conjugate acid}}{H_3O^+(aq)} + \underset{\text{Conjugate base}}{Cl^-(aq)}$$

In this reaction, hydrogen chloride is the hydrogen-ion donor. Thus, it is by definition a Brønsted-Lowry acid. Water is the hydrogen-ion acceptor and a Brønsted-Lowry base. The chloride ion is the conjugate base of the acid HCl. The hydronium ion is the conjugate acid of the base water.

Figure 19.6 shows the reaction that takes place when sulfuric acid dissolves in water. The products of this reaction are hydronium ions and hydrogen sulfate ions. Use the figure to identify the two conjugate acid-base pairs.

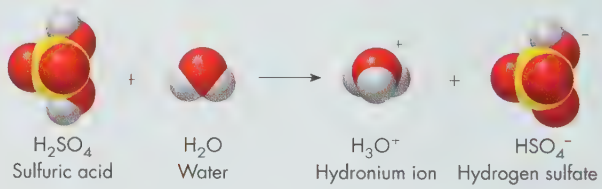

Figure 19.6 Sulfuric Acid When sulfuric acid and water react, they form hydronium ions and hydrogen sulfate ions. **Identify** ***Which product is the conjugate acid, and which is the conjugate base?***

Differentiated Instruction

L1 STRUGGLING STUDENTS Help students create a concept map that connects the three acid-base theories. Assist students in choosing connecting words and phrases. Encourage students to use both names and chemical symbols when referring to ions, and electron dot structures to illustrate Lewis acids and bases.

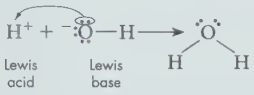
ELL ENGLISH LANGUAGE LEARNERS To help students visualize words with the prefix *amph-*, show students a photo of an amphibian, such as a frog or salamander, and explain that it is an animal with aquatic larvae that have gills and grow into air-breathing adults with lungs Then show students a photo of an amphibious airplane and direct them to answer the reading support question.

L3 ADVANCED STUDENTS Have students study a college text to find support for the following statement: *The formation of amphoteric hydroxides is a characteristic of metalloids*. Then have them write a brief paragraph explaining why metalloids have this characteristic.

Amphoteric Substances Look at Table 19.3. Note that water appears in both the list of acids and the list of bases. Sometimes water accepts a hydrogen ion. At other times, it donates a hydrogen ion. How water behaves depends on the other reactant. A substance that can act as either an acid or a base is said to be **amphoteric.** Water is amphoteric. In the reaction with hydrochloric acid, water accepts a proton and is therefore a base. In the reaction with ammonia, water donates a proton and is therefore an acid. Look for two other substances in Table 19.3 that are amphoteric.

Table 19.3

Some Conjugate Acid-Base Pairs



Acid	Base
HCl	Cl^-
H_2SO_4	HSO_4^-
H_3O^+	H_2O
HSO_4^-	SO_4^{2-}
CH_3COOH	CH_3COO^-
H_2CO_3	HCO_3^-
HCO_3^-	CO_3^{2-}
NH_4^+	NH_3
H_2O	OH^-

Lewis Acids and Bases

How did Lewis define an acid and a base?

The work that Gilbert Lewis (1875–1946) did on bonding led to a new concept of acids and bases. **According to Lewis, an acid accepts a pair of electrons and a base donates a pair of electrons during a reaction.** This definition is more general than those offered by Arrhenius or by Brønsted and Lowry. A **Lewis acid** is a substance that can accept a pair of electrons to form a covalent bond. Similarly, a **Lewis base** is a substance that can donate a pair of electrons to form a covalent bond.

The Lewis definitions include all the Brønsted-Lowry acids and bases. Consider the reaction of H^+ and OH^-. The hydrogen ion donates itself to the hydroxide ion. Therefore, H^+ is a Brønsted-Lowry acid and OH^- is a Brønsted-Lowry base. The hydroxide ion can bond to the hydrogen ion because it has an unshared pair of electrons. Thus, OH^- is also a Lewis base, and H^+, which accepts the pair of electrons, is a Lewis acid.

A second example of a reaction between a Lewis acid and a Lewis base is what happens when ammonia dissolves in water. Hydrogen ions from the dissociation of water are the electron-pair acceptor and the Lewis acid. Ammonia is the electron-pair donor and the Lewis base.

Table 19.4 compares the definitions of acids and bases. The Lewis definition is the broadest. It extends to compounds that the Brønsted-Lowry theory does not classify as acids and bases. Sample Problem 19.1 provides some examples of those compounds.

Table 19.4

Acid-Base Definitions

Type	Acid	Base
Arrhenius	H^+ producer	OH^- producer
Brønsted-Lowry	H^+ donor	H^+ acceptor
Lewis	electron-pair acceptor	electron-pair donor

READING SUPPORT

Building Vocabulary: ***Prefixes*** The prefix *amphi-* is from a Greek word meaning "of both kinds." An amphibian is an animal that is capable of living both on land and in the water. ***What does it mean to describe an airplane as*** **amphibious?**

UbD Check for Understanding

What distinguishes an acid from a base in the Brønsted-Lowry theory?

Assess students' knowledge about the Brønsted-Lowry theory by asking them to fill in the blank of the following prompt:

Ammonia is a base because it _____ a hydrogen ion to become a hydronium ion.

(accepts)

ADJUST INSTRUCTION If students are having trouble answering, have them write the chemical formulas for ammonia and the ammonium ion. Then have students decide whether a hydrogen ion was donated or accepted by ammonia.

Explore

Lewis Acids and Bases

APPLY CONCEPTS Point out that Lewis was the first scientist to discuss the significance of electron pairs in bonding, providing the basis for Lewis electron-dot diagrams. Explain that his theory of acids and bases was an extension of his concept of electron pairs. **Ask** A Lewis acid accepts a pair of electrons to form what type of bond? *(covalent bond)* **Ask** Does a Lewis base accept or donate a pair of electrons to form a covalent bond? *(donates)*

Extend

Explain that many cleaning supplies contain acids or bases. Tell students to go to local grocery, hardware, or home supply stores and study the labels on various cleaning products, such as those that clean lime deposits from tile and porcelain or mortar stains from brick and tile. Have students record the name of each cleaning product, the purpose of the product, and the specific name of the acid or base in the product. Explain that some of the chemical names may be familiar, but others, such as *muriatic acid*, may not be. Have students determine whether the unfamiliar names are older common names, and have them identify these chemicals by both their common and official names.

Answers

READING SUPPORT An amphibious airplane is designed to take off from and land on either land or water.

Explain

Sample Practice Problem

Identify each reactant as an acid or a base.

$NaHCO_3 + HCl \rightarrow H_2CO_3 + NaCl$

($NaHCO_3$ is the base; HCl is the acid.)

Evaluate

Informal Assessment

Have students use hydrochloric acid and ammonia as examples to illustrate the differences between the three methods for classifying acids and bases. Then direct students to complete the 19.1 Lesson Check.

Reteach

Review the concept of conjugate acids and bases by first writing on the board the equilibrium equation for the conversion of ammonia and water to ammonium ions and hydroxide ions. Label the acid, base, conjugate acid, and conjugate base. Beneath that, write the reverse reaction. Stress that for the purpose of identifying conjugate acid-base pairs, the reactants of the forward reaction are considered to be the acid and the base, and the products of the reaction are their conjugates. Next, label the reactants and products of the reverse reaction. Point out that because the reaction is proceeding in the reverse direction, ammonium ions and hydroxide ions are now considered the acid and base, and ammonia and water are the conjugates.

Answers

SAMPLE PROBLEM 19.1

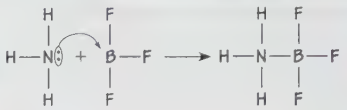
1. **a.** H is the Lewis acid; H_2O is the Lewis base.
   b. $AlCl_3$ is the Lewis acid; Cl is the Lewis base.
2. Lewis base; it has a nonbonding pair of electrons that it can donate.

SampleProblem 19.1

Identifying Lewis Acids and Bases

Identify the Lewis acid and the Lewis base in this reaction between ammonia and boron trifluoride.

$$NH_3 + BF_3 \longrightarrow NH_3BF_3$$



1 Analyze **Identify the relevant concepts.** When a Lewis acid reacts with a Lewis base, the base donates a pair of electrons and the acid accepts the donated pair.

2 Solve **Apply the concepts to this problem.**

Draw electron dot structures to identify which reactant has an unshared pair of electrons.

Identify the reactant with the unshared pair of electrons and the reactant that can accept the pair of electrons.

Ammonia has an unshared pair of electrons to donate. The boron atom can accept the donated electrons.

Classify the reactants based on their behavior.

Lewis bases donate a pair of electrons, so ammonia is the Lewis base. Lewis acids accept a pair of electrons, so boron trifluoride is the Lewis acid.

1. Identify the Lewis acid and Lewis base in each reaction.
   a. $H^+ + H_2O \longrightarrow H_3O^+$
   b. $AlCl_3 + Cl^- \longrightarrow AlCl_4^-$

2. Predict whether PCl_3 would be a Lewis acid or a Lewis base in typical chemical reactions. Explain your prediction.

19.1 LessonCheck

3. **Review** What is the Arrhenius definition of an acid and a base?
4. **Describe** How are acids and bases defined by the Brønsted-Lowry theory?
5. **Explain** How did Lewis broaden the definition of acids and bases?
6. **Compare and Contrast** How are the properties of acids and bases similar? How are they different?
7. **Classify** Determine whether the following acids are monoprotic, diprotic, or triprotic:
   a. H_2CO_3 **b.** H_3PO_4 **c.** HCl **d.** H_2SO_4
8. **Apply Concepts** Write a chemical equation for the ionization of HNO_3 in water and for the reaction of CO_3^{2-} with water. Identify the hydrogen-ion donor and the hydrogen-ion acceptor in each equation. Then, label each conjugate acid-base pair in the two equations.

BIGIDEA REACTIONS

9. Some household drain cleaners contain both sodium hydroxide and small particles of aluminum or zinc. Research how adding these metals can increase the effectiveness of the product.

Lesson Check Answers

3. An acid gives hydrogen ions. A base gives hydroxide ions.
4. Acids are hydrogen-ion donors and bases are hydrogen-ion acceptors.
5. A Lewis acid is an electron-pair acceptor; a Lewis base is an electron-pair donor.
6. Both are electrolytes and change the color of an acid-base indicator. Acids have a sour taste; bases taste bitter.
7. **a.** diprotic
   b. triprotic
   c. monoprotic
   d. diprotic
8. $HNO_3 + H_2O \rightarrow H_3O^+ + NO_3^-$; HNO_3 is the hydrogen-ion donor; its conjugate base is NO_3^-. H_2O is the hydrogen-ion acceptor; its conjugate acid is H_3O^+.
   $CO_3^{2-} + H_2O \rightleftharpoons HCO_3^- + OH^-$; CO_3^{2-} is the hydrogen ion acceptor; its conjugate acid is HCO_3^-. H_2O is the hydrogen-ion donor; its conjugate base is OH^-.
9. **BIG**IDEA The reaction of NaOH with aluminum generates heat, which softens greases and oils and hydrogen, which agitates the mixture.

19.2 Hydrogen Ions and Acidity

C.8.2 Properties of acids and bases; C.8.4 Calculate pH and hydronium ion concentration.

CHEMISTRY & YOU

Q: *What factors do you need to control so a fish has healthy water to live in?* Goldfish can live for 20 years or more in an aquarium if the conditions are right. The water in the aquarium must be cleaned regularly. You must also control the temperature of the water. In this lesson, you will study another factor that affects the ability of fish to survive.

Key Questions

- ***How are [H⁺] and [OH⁻] related in an aqueous solution?***
- ***How is pH used to classify a solution as neutral, acidic, or basic?***
- ***What are two methods that are used to measure pH?***

Vocabulary

- self-ionization
- neutral solution
- ion-product constant for water (K_w)
- acidic solution
- basic solution
- pH

Hydrogen Ions From Water

How are [H⁺] and [OH⁻] related in an aqueous solution?

Water molecules are highly polar and are in constant motion, even at room temperature. On occasion, the collisions between water molecules are energetic enough for a reaction to occur. When this happens, a hydrogen ion is transferred from one water molecule to another, as illustrated below. A water molecule that gains a hydrogen ion becomes a hydronium ion (H_3O^+). A water molecule that loses a hydrogen ion becomes a hydroxide ion (OH^-).

H_2O Water molecule + H_2O Water molecule ⇌ H_3O^+ Hydronium ion + OH^- Hydroxide ion

Self-Ionization of Water The reaction in which water molecules produce ions is called the **self-ionization** of water. This reaction can be written as a simple dissociation.

$$H_2O(l) \rightleftharpoons \underset{\text{Hydrogen ion}}{H^+(aq)} + \underset{\text{Hydroxide ion}}{OH^-(aq)}$$

In water or in an aqueous solution, hydrogen ions are always joined to water molecules as hydronium ions. Yet chemists may still refer to these ions as hydrogen ions or even protons. In this textbook, either H^+ or H_3O^+ is used to represent hydrogen ions in aqueous solution.

The self-ionization of water occurs to a very small extent. In pure water at 25°C, the concentration of hydrogen ions is only $1 \times 10^{-7} M$. The concentration of OH^- is also $1 \times 10^{-7} M$ because the numbers of H^+ and OH^- ions are equal in pure water. Any aqueous solution in which $[H^+]$ and $[OH^-]$ are equal is a **neutral solution.**

Key Objectives

19.2.1 DESCRIBE how $[H^+]$ and $[OH^+]$ are related in an aqueous solution.

19.2.2 CLASSIFY a solution as neutral, acidic, or basic by using pH.

19.2.3 IDENTIFY two methods that are used to measure pH.

Additional Resources

Reading and Study Workbook, Lesson 19.2

PearsonChem.com

Engage

CHEMISTRY & YOU Have students read the text that opens the lesson. Ask students to suggest other factors that might affect the ability of fish to survive, but do not provide the answer at this point.

Activate Prior Knowledge

Ask students to define the term *amphoteric*. *(A substance that can act as both an acid and a base is amphoteric.)* Then, ask them to explain why water is considered amphoteric. *(It can gain a proton to form a hydronium ion or lose a proton to form a hydroxide ion.)*

IN ACADEMIC STANDARDS for SCIENCE

- Develop explanations based on reproducible data and observations gathered during laboratory investigations.

C.8.2 Describe the characteristic properties of acids and bases.

C.8.4 Given the hydronium (H3O+) ion concentration in a solution, calculate the pH, and vice versa. Explain the meaning of these values.

Focus on ELL

1 CONTENT AND LANGUAGE Write the key questions on the board. As a class, work to paraphrase these questions so they are easier to understand. Read aloud each new paraphrased question and discuss what students have learned previously that will help them in this lesson.

2 FRONTLOAD THE LESSON Ask a student volunteer to explain the process for maintaining the water in a swimming pool or a hot tub. Guide the volunteer to share how he or she measures the conditions of the water and then the type of chemicals used to adjust the water conditions.

3 COMPREHENSIBLE INPUT Remind students that square brackets around a chemical formula indicate a molar concentration (moles per liter). Write the equation for K_w on the board as shown on page 654. Then rewrite the equation, substituting $1 \times 10^{-7} M$ for $[H^+]$ and $[OH^-]$ to show how the value $1 \times 10^{-14} M$ is determined.

Foundations for Reading

BUILD VOCABULARY Guide students to use a compare-and-contrast table to define and then to compare and contrast the properties of a *neutral solution*, an *acid solution*, and a *basic solution*.

READING STRATEGY Have students write at least two questions that challenge them to investigate the relationships between two or more vocabulary words or concepts. Then, have students answer their questions as they read the lesson.

Explain

Hydrogen Ions From Water

USE MODELS Direct students to examine the illustration of the self-ionization of water. On the board, show how two water molecules can react to yield a hydronium ion and a hydroxide ion. **Ask** Which element is donating a pair of electrons? *(oxygen)* **Ask** Which element is accepting a pair of electrons? *(hydrogen)*

MAKING CONNECTIONS Have students look at Figure 19.7. Remind students of the hydrochloric acid–zinc metal demonstration they observed in Lesson 19.1. Point out that pitting of the metal guitar parts resulted from a similar reaction between hydrochloric acid and the metal.

Figure 19.7 Aged by Acid Sometimes guitar players want a new guitar to look like it is old or "vintage." The guitarist can remove the shiny new metal parts of the guitar and expose them to hydrochloric acid. The acid will make the metal parts look dull. Both of the guitars in the photo below are new, but the bottom one has been aged with acid.

Ion-Product Constant for Water The ionization of water is a reversible reaction, so Le Châtelier's principle applies. Adding either hydrogen ions or hydroxide ions to an aqueous solution is a stress to the system. In response, the equilibrium will shift toward the formation of water. The concentration of the other ion will decrease. In any aqueous solution, when $[H^+]$ increases, $[OH^-]$ decreases. Likewise, when $[H^+]$ decreases, $[OH^-]$ increases.

$$H^+(aq) + OH^-(aq) \rightleftharpoons H_2O(l)$$

For aqueous solutions, the product of the hydrogen-ion concentration and the hydroxide-ion concentration equals 1.0×10^{-14}.

$$[H^+] \times [OH^-] = 1.0 \times 10^{-14}$$

This equation is true for all dilute aqueous solutions at 25°C. When substances are added to water, the concentrations of H^+ and OH^- may change. However, the product of $[H^+]$ and $[OH^-]$ does not change. The product of the concentrations of the hydrogen ions and hydroxide ions in water is called the **ion-product constant for water (K_w).**

$$K_w = [H^+] \times [OH^-] = 1.0 \times 10^{-14}$$

Acidic Solutions Not all solutions are neutral. When some substances dissolve in water, they release hydrogen ions. For example, when hydrogen chloride dissolves in water, it forms hydrochloric acid.

$$HCl(aq) \longrightarrow H^+(aq) + Cl^-(aq)$$

In hydrochloric acid, the hydrogen-ion concentration is greater than the hydroxide-ion concentration. (The hydroxide ions come from the self-ionization of water.) A solution in which $[H^+]$ is greater than $[OH^-]$ is an **acidic solution.** In acidic solutions, the $[H^+]$ is greater than $1 \times 10^{-7} M$. Figure 19.7 shows a guitar that was artificially aged by using hydrochloric acid.

Basic Solutions When sodium hydroxide dissolves in water, it forms hydroxide ions in solution.

$$NaOH(aq) \longrightarrow Na^+(aq) + OH^-(aq)$$

In such a solution, the hydrogen-ion concentration is less than the hydroxide-ion concentration. Remember, the hydrogen ions are present from the self-ionization of water. A **basic solution** is one in which $[H^+]$ is less than $[OH^-]$. The $[H^+]$ of a basic solution is less than $1 \times 10^{-7} M$. Basic solutions are also known as alkaline solutions.

Differentiated Instruction

L1 STRUGGLING STUDENTS Students without a solid foundation in scientific notation may have trouble understanding the relationship between hydrogen- and hydroxide-ion concentrations. Draw diagrams to help students visualize the shift in equilibrium that occurs when one or the other type of ion is added or removed.

ELL ENGLISH LANGUAGE LEARNERS Discuss the meaning of *neutral* in the following sentences: *Switzerland was neutral in World War II. The umpire should be neutral during a baseball game. A neutral particle carries no overall electric charge. Then discuss its meaning in terms of pH.*

L1 LESS PROFICIENT READERS Have students create flashcards to help remember the symbols or abbreviations used in this lesson. For example, square brackets represent *molar concentration*, double arrows represent a reversible reaction, and *(aq)* means *aqueous*.

Sample Problem 19.2

Using the Ion-Product Constant for Water

If the $[H^+]$ in a solution is $1.0 \times 10^{-5} M$, is the solution acidic, basic, or neutral? What is the $[OH^-]$ of this solution?

KNOWNS
$[H^+] = 1.0 \times 10^{-5} M$
$K_w = 1 \times 10^{-14}$

UNKNOWNS
Is the solution acidic, basic, or neutral?
$[OH^-] = ?M$

1 Analyze **List the knowns and the unknowns.** Use the expression for the ion-product constant for water and the known concentration of hydrogen ions to find the concentration of hydroxide ions.

2 Calculate **Solve for the unknowns.**

Use $[H^+]$ to determine whether the solution is acidic, basic, or neutral

$[H^+]$ is $1.0 \times 10^{-5} M$, which is greater than $1.0 \times 10^{-7} M$. Thus, the solution is acidic.

Rearrange the expression for the ion-product constant to solve for $[OH^-]$

$$K_w = [H^+] \times [OH^-]$$

$$[OH^-] = \frac{K_w}{[H^+]}$$

When you divide numbers written in scientific notation, subtract the exponent in the denominator from the exponent in the numerator

Substitute the known values of $[H^+]$ and K_w, then solve for $[OH^-]$

$$[OH^-] = \frac{1.0 \times 10^{-14}}{1.0 \times 10^{-5}}$$

$$= 1.0 \times 10^{-9} M$$

3 Evaluate **Does the result make sense?** If $[H^+]$ is greater than $1.0 \times 10^{-7} M$, then $[OH^-]$ must be less than $1.0 \times 10^{-7} M$. $1 \times 10^{-9} M$ is less than $1 \times 10^{-7} M$. To check your calculation, multiply the values for $[H^+]$ and $[OH^-]$ to make sure the result equals 1×10^{-14}.

For Problem 11, rearrange the expression for the ion-product constant to solve for $[H^+]$.

10. Classify each solution as acidic, basic, or neutral.
- **a.** $[H^+] = 6.0 \times 10^{-10} M$
- **b.** $[OH^-] = 3.0 \times 10^{-2} M$
- **c.** $[H^+] = 2.0 \times 10^{-7} M$
- **d.** $[OH^-] = 1.0 \times 10^{-7} M$

11. If the hydroxide-ion concentration of an aqueous solution is $1 \times 10^{-3} M$, what is the $[H^+]$ in the solution? Is the solution acidic, basic, or neutral?

Foundations for Math

SUBTRACTING INTEGERS When explaining the power of a quotient, make sure students remember how to subtract integers. Tell students that to subtract an integer, you simply add the opposite. Use a number line to prove why this method works.

In **Sample Problem 19.2,** show students that the exponent for the quotient can be determined by subtracting the integer exponents. Point out that to find the difference of $-14 - (-5)$, *you add the opposite*. Change the subtraction sign to a positive and change the sign on the subtrahend to its opposite—in this case, to a +. So, $-14 - (-5) = -14 + 5 = -9$.

Extend

Tell students that pure water (i.e., distilled, deionized water) self-ionizes to form hydrogen and hydroxide ions, yet it does not conduct electric current well. **Ask** Why does this occur? *(Pure water is a poor conductor because the concentrations of the ions are low.)* **Ask** Why do tap water and water from natural sources conduct electricity? *Water from these sources contains dissolved ions in large enough concentrations to conduct an electrical current.)*

USE CONTEXT CLUES Draw students' attention to the final sentence on the preceding page. Explain that sometimes words that mean the same thing may be interchanged in the sample problems or the text, as in the case of *alkaline* and *basic*. **Ask** What are some other ways that can be used to describe hydrogen ions? *(H^+, H_3O^+, hydronium ions, and protons)* Alert students to use context clues to help them understand an unfamiliar term, because the term might be just another way of stating something they already know.

Sample Practice Problem

The $[OH^-]$ of a grapefruit juice is $3.4 \times 10^{-11} M$. What is the $[H^+]$ of this solution? Is the solution acidic or basic? *(2.9×10^{-4}M; acidic)*

Answers

SAMPLE PROBLEM 19.2

10. **a.** basic **b.** basic **c.** acidic **d.** neutral
11. $1.0 \times 10^{-11} M$; basic

Explain

The pH Concept

START A CONVERSATION Introduce pH as a simpler way to express hydrogen-ion concentration. State the following sentences aloud.

- The pH of a solution is 3.00.
- The hydrogen ion concentration is equal to 1.0×10^{-3} moles per liter.

Point out that the two sentences express exactly the same information about the hydrogen ion concentration of a solution, but the first sentence expresses the information in a more concise manner.

APPLY CONCEPTS For students who have little or no experience with logarithms, explain that pH is found by taking the negative of the power (exponent) of 10 that expresses the hydrogen ion concentration. Show students this example: $[H^+] = 0.00010 = 1.0 \times 10^{-4}M$; $pH = -\log_{10}(1.0 \times 10^{-4}) = 4.00$. Explain that most pH values are positive, but negative values are also possible. Assuming 100% ionization, for example, the pH of a 10*M* HCl solution is –1.00. Challenge students to prove mathematically why this is true. *($10M = 1 \times 10^1 M$; $pH = -\log_{10}(1.0 \times 10^1) = -1.00$).*

CHEMISTRY & YOU *Sample answer*: The difference in the ideal pH range most likely reflects the typical pH ranges in the natural environments of freshwater and saltwater fish.

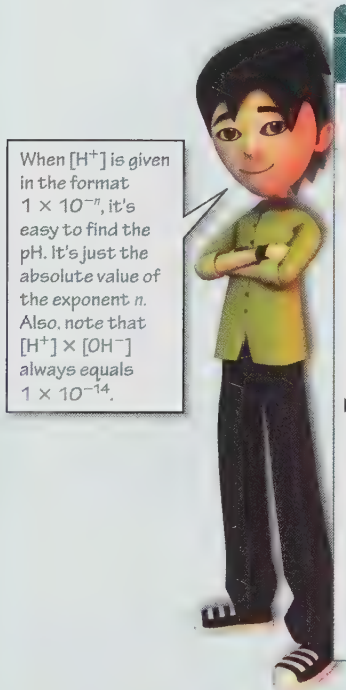
CHEMISTRY & YOU

Q: *In an aquarium, the pH of water is another factor that affects the ability of fish to survive. Most freshwater fish need a slightly acidic or neutral pH. For a saltwater tank, the ideal pH is slightly basic. What might explain this difference in the ideal pH range?*

The pH Concept

How is pH used to classify a solution as neutral, acidic, or basic?

Expressing hydrogen-ion concentration in molarity is not practical. A more widely used system for expressing $[H^+]$ is the pH scale, proposed in 1909 by the Danish scientist Søren Sørensen. The pH scale ranges from 0 to 14.



Hydrogen Ions and pH The **pH** of a solution is the negative logarithm of the hydrogen-ion concentration. The pH may be represented mathematically using the following equation:

$$pH = -\log[H^+]$$

In pure water or a neutral solution, the $[H^+] = 1 \times 10^{-7}M$, and the pH is 7.

$$\begin{aligned} pH &= -\log(1 \times 10^{-7}) \\ &= -(\log 1 + \log 10^{-7}) \\ &= -(0.0 + (-7.0)) = 7.0 \end{aligned}$$

If the $[H^+]$ of a solution is greater than $1 \times 10^{-7}M$, the pH is less than 7.0. If the $[H^+]$ of the solution is less than $1 \times 10^{-7}M$, the pH is greater than 7.0. **A solution with a pH less than 7.0 is acidic. A solution with a pH of 7.0 is neutral. A solution with a pH greater than 7.0 is basic.** Table 19.5 summarizes the relationship among $[H^+]$, $[OH^-]$, and pH. It also indicates the pH values of some common aqueous systems, including milk and blood.

When $[H^+]$ is given in the format 1×10^{-n}, it's easy to find the pH. It's just the absolute value of the exponent *n*. Also, note that $[H^+] \times [OH^-]$ always equals 1×10^{-14}.

Table 19.5

Relationships Among $[H^+]$, $[OH^-]$, and pH

	$[H^+]$ (mol/L)	$[OH^-]$ (mol/L)	pH	
Increasing acidity	1×10^{0}	1×10^{-14}	0.0	1*M* HCl
	1×10^{-1}	1×10^{-13}	1.0	0.1*M* HCl
	1×10^{-2}	1×10^{-12}	2.0	Gastric juice
	1×10^{-3}	1×10^{-11}	3.0	Lemon juice
	1×10^{-4}	1×10^{-10}	4.0	Tomato juice
	1×10^{-5}	1×10^{-9}	5.0	Black coffee
	1×10^{-6}	1×10^{-8}	6.0	Milk
Neutral	1×10^{-7}	1×10^{-7}	7.0	Pure water, Blood
Increasing basicity	1×10^{-8}	1×10^{-6}	8.0	Seawater
	1×10^{-9}	1×10^{-5}	9.0	
	1×10^{-10}	1×10^{-4}	10.0	Milk of magnesia
	1×10^{-11}	1×10^{-3}	11.0	Household ammonia
	1×10^{-12}	1×10^{-2}	12.0	
	1×10^{-13}	1×10^{-1}	13.0	0.1*M* NaOH
	1×10^{-14}	1×10^{0}	14.0	1*M* NaOH

Professional Development Note

Ions in Water

All aqueous systems contain both hydrogen and hydroxide ions due to self-ionization of water. At 25°C, about 1 molecule of water out of 550,000,000 will dissociate. This amounts to 1 g of hydrogen ions and 17 g of hydroxide ions in 10,000,000 L of water. No matter how small the concentrations, both ions are always present in a water solution. The relationship between the concentrations of H^+ and OH^- in aqueous solutions at constant temperature is similar to the relationship between the pressure and volume of a gas at constant temperature. In both cases, the relationship is inverse. The product of the two quantities is a constant—as one quantity increases, the other decreases.

Calculating pH From $[H^+]$ Expressing $[H^+]$ in scientific notation can make it easier to calculate pH. For example, you would rewrite $0.0010M$ as $1.0 \times 10^{-3}M$. The coefficient 1.0 has two significant figures. The pH for a solution with this concentration is 3.00. The two numbers to the right of the decimal point represent the two significant figures in the concentration.

It is easy to find the pH for solutions when the coefficient is 1.0. The pH of the solution equals the exponent, with the sign changed from minus to plus. For example, a solution with $[H^+] = 1 \times 10^{-2}M$ has a pH of 2.0. When the coefficient is a number other than 1, you will need to use a calculator with a log function key to calculate pH.

SampleProblem 19.3

Calculating pH From $[H^+]$

What is the pH of a solution with a hydrogen-ion concentration of $4.2 \times 10^{-10}M$?

1 Analyze **List the known and the unknown.** To find the pH from the hydrogen-ion concentration, you use the equation $pH = -\log[H^+]$.

KNOWN	UNKNOWN
$[H^+] = 4.2 \times 10^{-10}M$	pH = ?

2 Calculate **Solve for the unknown.**

Start with the equation for finding pH from $[H^+]$.

$$pH = -\log[H^+]$$

Substitute the known $[H^+]$ and use the log function on your calculator to calculate the pH.

$$pH = -\log(4.2 \times 10^{-10})$$
$$= -(-9.37675)$$
$$= 9.37675$$
$$= 9.38$$

Round the pH to two decimal places because the hydrogen-ion concentration has two significant figures.

3 Evaluate **Does the result make sense?** The value of the hydrogen-ion concentration is between $1 \times 10^{-9}M$ and $1 \times 10^{-10}M$. So, the calculated pH should be between 9 and 10, which it is.

12. Find the pH of each solution.
- **a.** $[H^+] = 0.045M$
- **b.** $[H^+] = 8.7 \times 10^{-6}M$
- **c.** $[H^+] = 0.0015M$
- **d.** $[H^+] = 1.2 \times 10^{-3}M$

13. What are the pH values of the following solutions, based on their hydrogen-ion concentrations?
- **a.** $[H^+] = 1.0 \times 10^{-12}M$
- **b.** $[H^+] = 1 \times 10^{-4}M$

Foundations for Math

PROPERTIES OF LOGARITHMS Show students that the distributive property holds true for logarithms. Students who are not proficient with a scientific calculator, students who want to check their answers for sense, and even mathematically proficient students may benefit from the following kind of derivation.

In **Sample Problem 19.3,** show students that in Step 2 the value of $\log(4.2 \times 10^{-10})$ can be determined by breaking the problem into simpler parts. Point out that by the distributive property, the expression $\log(4.2 \times 10^{-10})$ is equivalent to $\log(4.2) + \log(10^{-10})$. By definition of logarithms, show students that $\log(10^{-10}) = -10$. Now the expression can be simplified as $\log(4.2) + (-10)$, or $\log(4.2) - 10$.

Explain

MAKE CONNECTIONS Have students examine Table 19.5. Point out that as the concentration of hydrogen ions in an aqueous solution increases, the concentration of hydroxide ions in the same solution decreases so that the product of the two concentrations always equals $1 \times 10^{-14}M$ at 25°C. The pH scale in the third column shows the relationship between the concentrations of the two ions and the resulting pH of the solution. Have students compare the pOH of a solution by asking them if there are any OH^- ions in an acidic solution with a pH of 3.25. *(Yes, there are always some OH^- ions in an aqueous solution.)* **Ask** How do you know this? *(The product of the hydrogen ion concentration must always equal K_w.)* Have students calculate the pOH of this solution. *(pH + pOH = 14; pOH = 14 – 3.25 = 10.75)*

Sample Practice Problem

What are the pH values of the following three solutions, based on their hydrogen ion concentrations?

- **a.** $[H^+] = 1.0 \times 10^{-5}M$ *(5.00)*
- **b.** $[H^+] = 1.0 \times 10^{-9}M$ *(9.00)*
- **c.** $[H^+] = 0.001M$ *(3.0)*

Extend

Connect to GEOLOGY

Point out to students that the pH scale can be compared to the Richter scale, which measures the magnitude of earthquakes and is also based on a logarithmic scale. Explain that on each scale, a change of one unit represents a tenfold change in the value being measured. As a comparison, show students that on the Richter scale, a tremor measuring 4.0 is ten times as strong as one measuring 3.0 and on the pH scale, the hydrogen-ion concentration of a solution with a pH of 3.0 is ten times the concentration of a solution with a pH of 4.0. Have students research five of the most recent earthquakes. Instruct them to graph and compare the magnitudes.

SAMPLE PROBLEM 19.3

12. **a.** pH = 1.35 **c.** pH = 2.82
b. pH = 5.06 **d.** pH = 2.92

13. **a.** $pH = -\log[H^+] = -\log(1.0 \times 10^{-12}) = 12$
b. $pH = -\log[H^+] = -\log(1 \times 10^{-4}) = 4$

Explain

Sample Practice Problem

A beverage that is of 88% apple juice has a pH of 2.7. What is the hydrogen-ion concentration of the beverage? *(1.2 × 10^{-3}M)*

CRITICAL THINKING Challenge students to hypothesize what the letters *p* and *H* represent in the abbreviation *pH*. As a hint, remind them that pH is an expression of the hydronium ion concentration, while pOH is an expression of the hydroxide concentration in an aqueous solution. *(Students should correctly deduce that the* H *represents something having to do with hydronium ions.)* Write the equation pH = –log[H_3O^+] on the board, using a contrasting color to write *p* and *–log*. Give students an opportunity to suggest that *p* is another way of representing the negative logarithm.

Explore

Teacher Demo

PURPOSE Students will observe a color change resulting from a change in pH.

MATERIALS lemon juice, tea, antacid tablet, glass of 10% grape juice, household ammonia

PROCEDURE Without explanation, add lemon juice to tea, add an antacid tablet to grape juice, and add a few drops of ammonia to grape juice. Have the students try to explain the changes they observe.

EXPECTED OUTCOME Color changes occur when lemon juice, an antacid tablet, or ammonia is added. The pigments in tea and grape juice are weak acids that change color with varying pH.

Calculating [H$^+$] From pH You can calculate the hydrogen-ion concentration of a solution if you know the pH. If the pH is an integer, it is easy to find the value of [H$^+$]. For a pH of 9.0, [H$^+$] = 1 × 10^{-9}*M*. For a pH of 4.0, [H$^+$] is 1 × 10^{-4}*M*.

However, most pH values are not whole numbers. For example, milk of magnesia has a pH of 10.50. The [H$^+$] must be less than 1 × 10^{-10}*M* (pH 10.0) but greater than 1 × 10^{-11}*M* (pH 11.0). The hydrogen-ion concentration is 3.2 × 10^{-11}*M*. When the pH value is not a whole number, you will need a calculator with an antilog (10^x) function to get an accurate value for the hydrogen-ion concentration.

SampleProblem 19.4

Calculating [H$^+$] From pH

The pH of an unknown solution is 6.35. What is the hydrogen-ion concentration of the solution?

KNOWN
pH = 6.35

UNKNOWN
[H$^+$] = ?*M*

1 Analyze **List the known and the unknown.** You will use the antilog function of your calculator to find the concentration.

2 Calculate **Solve for the unknown.**

First, simply swap the sides of the equation for finding pH and substitute the known value.

$pH = -\log [H^+]$

$-\log [H^+] = pH$

$-\log [H^+] = 6.35$

Change the signs on both sides of the equation and then solve for the unknown.

$\log [H^+] = -6.35$

$[H^+] = \text{antilog}\,(-6.35)$

Use the antilog (10^x) function on your calculator to find [H$^+$]. Report the answer in scientific notation.

$[H^+] = 4.5 \times 10^{-7} M$

On most calculators, use the 2nd or the INV key followed by log to get the antilog.

3 Evaluate **Does the result make sense?** The pH is between 6 and 7. So, the hydrogen ion concentration must be between 1 × 10^{-6}*M* and 1 × 10^{-7}*M*. The answer is rounded to two significant figures because the pH was measured to two decimal places.

14. Calculate [H$^+$] for each solution.
- **a.** pH = 5.00
- **b.** pH = 12.83

15. What are the hydrogen-ion concentrations for solutions with the following pH values?
- **a.** 4.00
- **b.** 11.55

Foundations for Math

LOGS AND ANTILOGS Explain that pH is based on common, or base 10, logarithms. A common logarithm is an exponent of the number 10, and 10 raised to that exponent is its antilog. For example, log (10,000) = log (10^4) = 4. In this example, 4 is the log and its antilog is 10^4. Have students consider the equation –log [H$^+$] = pH. Rewriting to isolate the log gives log [H$^+$] = –pH. The log is –pH and its antilog is 10^{-pH}. So [H$^+$] = 10^{-pH}.

For **Sample Problem 19.4**, [H$^+$] = antilog (–6.35) can be rewritten as [H$^+$] = 10$^{-6.35}$. This relationship can help students remember that they need to use the 10^x function on their calculators to determine [H$^+$] and to include the minus sign when making their antilog calculations. Suggest to students that they write [H$^+$] = 10^{-pH} in their notebooks along with their notes on how to use the antilog function of their calculator.

Calculating pH From [OH⁻] If you know the [OH⁻] of a solution, you can find its pH. Recall that the ion-product constant for water defines the relationship between [H⁺] and [OH⁻]. Therefore, you can use the ion-product constant for water to determine [H⁺] for a known [OH⁻]. Then, you use [H⁺] to calculate the pH. For practice, try doing Sample Problem 19.5.

Sample Problem 19.5

Calculating pH From [OH⁻]

What is the pH of a solution if $[OH^-] = 4.0 \times 10^{-11} M$?

1 Analyze **List the knowns and the unknown.**

To find [H⁺], divide K_w by the known [OH⁻]. Then, calculate pH as you did in Sample Problem 19.3.

KNOWNS
$[OH^-] = 4.0 \times 10^{-11} M$
$K_w = 1.0 \times 10^{-14}$

UNKNOWN
pH = ?

2 Calculate **Solve for the unknown.**

Start with the ion-product constant to find [H⁺]. Rearrange the equation to solve for [H⁺].

$$K_w = [OH^-] \times [H^+]$$

$$[H^+] = \frac{K_w}{[OH^-]}$$

Substitute the values for K_w and [OH⁻] to find [H⁺].

$$[H^+] = \frac{1.0 \times 10^{-14}}{4.0 \times 10^{-11}} = 0.25 \times 10^{-3} M$$

$$= 2.5 \times 10^{-4} M$$

Next, use the equation for finding pH. Substitute the value for [H⁺] that you just calculated.

$$pH = -\log [H^+]$$

$$= -\log (2.5 \times 10^{-4})$$

Use a calculator to find the log.

$$= -(-3.60205)$$

$$= 3.60$$

Round the pH to two decimal places because the [OH⁻] has two significant figures.

3 Evaluate **Does the result make sense?** A solution in which [OH⁻] is less than $1 \times 10^{-7} M$ is acidic because [H⁺] is greater than $1 \times 10^{-7} M$. The hydrogen-ion concentration is between $1 \times 10^{-3} M$ and $1 \times 10^{-4} M$. Thus, the pH should be between 3 and 4.

16. Calculate the pH of each solution.
- **a.** $[OH^-] = 4.3 \times 10^{-5} M$
- **b.** $[OH^-] = 4.5 \times 10^{-11} M$

17. Calculate the pH of each solution.
- **a.** $[OH^-] = 5.0 \times 10^{-9} M$
- **b.** $[OH^-] = 8.3 \times 10^{-4} M$

Foundations for Math

NEGATIVE MULTIPLIERS Explain that when a negative sign is located just outside of a grouping symbol, the negative really represents the value –1. It is common in mathematics not to show the 1; explain that the 1 is "understood." Point out that since the negative is next to the grouping symbol, everything within the grouping symbol should be multiplied by –1.

In **Sample Problem 19.5,** students may attempt to calculate the log of -2.5×10^{-4}. Remind students that the log function serves as a grouping symbol, so the log should be calculated *before* multiplying by –1.

Explore

Class Activity

PURPOSE Students observe how a pH meter measures the pH of solutions.

MATERIALS several test tubes; 0.1*M* HCl; 0.1*M* NaOH; household products such as lemon juice, vinegar, shampoo, and liquid detergent; pH meter

PROCEDURE Set up test tubes with acids and bases of varying strength. In addition to HCl and NaOH, include household products such as lemon juice, vinegar, shampoo, and liquid detergent. Ask the students to predict the order from least acidic to most acidic and list their predictions in a table on the board. Use a pH meter to measure the pH of each solution. Explain that the reading on the pH meter depends upon the concentration of hydrogen ions in the solutions. Write the results on the board. Discuss any differences between students' predictions and the results of the experiment.

Explain

Sample Practice Problem

Calculate the pH of each solution.

- **a.** $[OH^-] = 1.0 \times 10^{-11}$ (*3.00*)
- **b.** $[H^+] = 7.7 \times 10^{-4}$ (*3.11*)

Answers

Measuring pH

Teacher Demo

PURPOSE Students observe how pH indicators react to the acidity of their environment.

MATERIALS 0.1% solutions of thymol blue, methyl red, bromothymol blue, and phenolphthalein; test tubes; aqueous buffers spanning pH 4 to pH 10 (Either create a range of buffers spanning pH 4 to pH 10 or higher, or purchase standard buffers with different pH values.)

PROCEDURE Explain that many natural and synthetic pigments are weak acids that change color with varying pH. Transfer a small volume of each buffer to a test tube. Label the tubes with their respective pH values. Add 5 drops of indicator to each test tube. Set up a separate rack of tubes for each indicator and ask students to infer the pH range for which each indicator is most suitable. Students should note the colors and pH values of the solutions in tubes. In addition, add 5 drops of the indicators to two or three tubes containing a solution with an unknown pH and have students estimate its pH value using the reference tubes.
Ask Why would an investigator prefer to use a pH meter to measure pH? *(Individual indicators are responsive only to pH changes in narrow ranges. Many different indicators are needed to span the entire pH range. A pH meter allows an investigator to collect quantitative values on a continuous basis throughout the entire pH range. The precision and accuracy of pH meters are superior to those of standard indicators. pH meters can be calibrated and used reliably at different temperatures.)*

Explain

USE VISUALS Have students examine Figure 19.9.
Ask Which indicator(s) would best show a change in pH from 4.6 to 4.9? *(Using both bromocresol green and methyl red would give the best results.)*

Measuring pH

What are two methods that are used to measure pH?

In many situations, knowing the pH is useful. A custodian might need to maintain the correct acid-base balance in a swimming pool. A gardener may want to know if a certain plant will thrive in a yard. A doctor might be trying to diagnose a medical condition. **Either acid-base indicators or pH meters can be used to measure pH.**

Acid-Base Indicators An indicator is often used for initial pH measurements and for samples with small volumes. An indicator (HIn) is an acid or a base that dissociates in a known pH range. Indicators work because their acid form and base form have different colors in solution. The following general equation represents the dissociation of an acid-base indicator (HIn).

$$\underset{\text{Acid form}}{HIn(aq)} \rightleftharpoons H^+(aq) + \underset{\text{Base form}}{In^-(aq)}$$

The acid form of the indicator (HIn) is dominant at low pH and high $[H^+]$. The base form (In^-) is dominant at high pH and high $[OH^-]$.

The change from dominating acid form to dominating base form occurs within a narrow range of about two pH units. Within this range, the color of the solution is a mixture of the colors of the acid and the base forms. If you know the pH range over which this color change occurs, you can make a rough estimate of the pH of a solution. At all pH values below this range, you would see only the color of the acid form. At all pH values above this range, you would see only the color of the base form.

For a more precise estimate of the solution's pH, you could repeat the test with indicators that have different pH ranges for their color change. Many indicators are needed to span the entire pH spectrum. Figure 19.8 shows the pH ranges of some common acid-base indicators.

Interpret Graphs

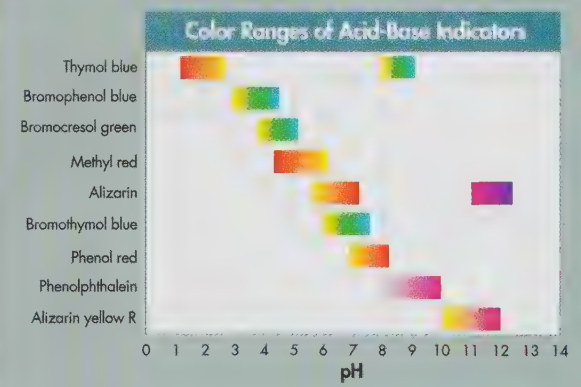

Figure 19.8 Each indicator is useful for a specific range of pH values.
a. Identify At a pH of 12, which indicator would be yellow?
b. Apply Concepts Which indicator could you use to show that the pH of a solution has changed from 3 to 5?
c. Make Generalizations What do you notice about the range over which each indicator changes color?

Differentiated Instruction

L3 ADVANCED LEARNERS Have students identify occupations in which people need to measure pH. Interested students may select a local person in an occupation from the list and ask to interview that person about his or her use of pH measurement. Have students write up their interviews as if they were preparing them for a blog.

L1 SPECIAL NEEDS STUDENTS Students with colorblindness will be unable to distinguish many of the color changes that are shown in Figure 19.8 and that occur during demonstrations, class activities, and labs involving color indicators. Pair these individuals with a lab partner who has normal vision, and provide these students with alternative assessment items when necessary.

LPR LESS PROFICIENT READERS Provide students with a copy of Figure 19.8, Have students write *acidic*, *neutral*, and *basic* below the pH values on the *x*-axis, using brackets to encompass pH ranges where appropriate. Have students refer to Table 19.5 for help. Encourage students to refer to the graph during the teacher demo.

Figure 19.9 Effects of Soil Acidity
Soil pH can affect how plants develop. **a.** In acidic soils, hydrangeas produce blue flowers. **b.** In basic soils, hydrangeas produce pink flowers.

Indicators have certain properties that limit their usefulness. The pH values of indicators are usually given for 25°C. At other temperatures, an indicator may change color at a different pH. If the solution being tested is not colorless, the color of the indicator may be misleading. Dissolved salts in a solution may affect an indicator's dissociation. Using indicator strips can help overcome these problems. An indicator strip is a piece of paper or plastic that has been soaked in an indicator, and then dried. The paper is dipped into an unknown solution. The color that results is compared with a color chart to measure the pH. Some indicator paper has absorbed multiple indicators. The colors that result will cover a wide range of pH values. Before planting the shrub shown in Figure 19.9, you might want to test the pH of your soil.

pH Meters Your chemistry laboratory probably has a pH meter. A pH meter is used to make rapid, continuous measurements of pH. The measurements of pH obtained with a pH meter are typically accurate to within 0.01 pH unit of the true pH. If the pH meter is connected to a computer or chart recorder, the user will have a record of the pH changes.

A pH meter can be easier to use than liquid indicators or indicator strips. As shown in Figure 19.10, the pH reading is visible in a display window on the meter. Hospitals use pH meters to find small but meaningful changes in the pH of blood and other body fluids. Sewage, industrial wastes, and soil pH are also easily monitored with a pH meter. The color and cloudiness of the solution do not affect the accuracy of the pH value obtained.

Figure 19.10 pH Meter
A pH meter provides a quick and accurate way to measure the pH of a system.

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the Quick Lab on the following page. Make sure each group has ELLs of varied language proficiencies so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Have students use colored markers correlated to a color key to record their observations.

INTERMEDIATE: LOW/HIGH Model Step 3 of the procedure–creating the pH scale. Then have students follow your example.

ADVANCED: LOW/HIGH Ask students to create a sorting method for less proficient students to use for help in answering Analyze and Conclude questions 3 and 4.

Evaluate

Informal Assessment

Have students use equations to describe the relationship between the concentrations of hydrogen and hydroxide ions in pure water and to show what happens to the equilibrium when HCl is added to water. Repeat the exercise with NaOH. *(At 25°C, $[H^+] \times [OH^-] = 1.0 \times 10^{-14}$. When acid is added, the $[H^+]$ increases and the $[OH^-]$ decreases. When base is added, the $[OH^-]$ increases and the $[H^+]$ decreases.)* Then direct students to complete the 19.2 Lesson Check.

Reteach

Review the key steps in calculating pH and the relationship between K_w, $[H^+]$, and $[OH^-]$. Then provide students with additional practice in calculating pH, $[H^+]$, and $[OH^-]$.

Answers

INTERPRET GRAPHS

a. methyl red
b. bromophenol blue or bromocresol green
c. The indicators change color over a very limited range of pH. This allows for a more accurate reading of pH change.

Explore

QuickLab

OBJECTIVE Students will measure the pH of various household materials by using a natural indicator and an indicator chart.

PREP TIME 20 minutes

CLASS TIME If the period allotted to lab work is short, spread the work over two days.

SAFETY Perform this lab in a well-ventilated room.

EXPECTED OUTCOME Students will use their natural indicators and pH scales to determine if tested materials are acidic, basic, or neutral.

ANALYZE AND CONCLUDE

1. The initial color is purple. In an acidic solution, the indicator is red; in a neutral solution, it is blue-purple; and in a basic solution, it is green.
2. Changes in the relative number of H^+ and OH^- ions present are responsible for the color changes.
3. Answers will vary depending on the materials chosen.
4. Personal hygiene items mainly test neutral; cleaning materials, such as soap, mainly test basic.

QuickLab

Indicators From Natural Sources

Purpose To measure the pH of household materials using a natural indicator

Materials

- red cabbage leaves
- 1-cup measure
- hot water
- 2 jars
- spoon
- cheesecloth
- 3 sheets of plain white paper
- transparent tape
- metric ruler
- pencil
- 10 small clear plastic cups
- permanent marker
- white vinegar (CH_3COOH)
- baking soda ($NaHCO_3$)
- spatula
- household ammonia
- dropper
- assorted household materials

Procedure

1. Put one-half cup of finely chopped red cabbage leaves in a jar and add one-half cup of hot water. Stir and crush the leaves with a spoon. Continue this process until the water has a distinct color.
2. Strain the mixture through a piece of clean cheesecloth into a clean jar. The liquid that collects in the jar is your indicator.
3. Tape three sheets of paper end to end. Draw a line along the center of the taped sheets. Label the line at 5-cm intervals with the numbers 1 to 14. This labeled line is your pH scale.
4. Use the permanent marker to label three cups vinegar, baking soda, and ammonia. Pour indicator into each cup to a depth of about 1 cm.
5. Add several drops of vinegar to the first cup. Use a spatula to add a pinch of baking soda to the second cup. Add several drops of ammonia to the third cup. The pH values for the solutions of vinegar, baking soda, and household ammonia are about 3, 9, and 11, respectively. Record the colors you observe at the correct locations on your pH scale.
6. Repeat the procedure for household items such as table salt, milk, lemon juice, laundry detergent, milk of magnesia, toothpaste, shampoo, and carbonated beverages.

Analyze and Conclude

1. **Observe** What color is the indicator in acidic, neutral, and basic solutions?
2. **Relate Cause and Effect** What caused the color of the indicator to change when a material was added to a cup?
3. **Classify** Divide the household materials you tested into three groups—acidic, basic, and neutral.
4. **Analyze Data** Which group contains items used for cleaning? Which group contains items used for personal hygiene?

19.2 LessonCheck

18. **Review** How are the concentrations of hydrogen ions and hydroxide ions related in an aqueous solution?
19. **Identify** What is the range of pH values in the following solutions?
    a. basic **b.** acidic **c.** neutral
20. **List** What methods can you use to measure the pH of a solution?
21. **Relate Cause and Effect** What happens to the $[H^+]$ as the pH of a solution increases?
22. **Calculate** Determine the pH of each solution.
    a. $[H^+] = 1 \times 10^{-6} M$
    b. $[H^+] = 0.00010 M$
    c. $[OH^-] = 1 \times 10^{-2} M$
    d. $[OH^-] = 1 \times 10^{-11} M$
23. **Compare** In terms of ion concentrations, how do basic solutions differ from acidic solutions?
24. **Calculate** Find the hydroxide-ion concentrations for solutions with the following pH values:
    a. 6.00 **b.** 9.00 **c.** 12.00

Lesson Check Answers

18. $[H^+] \times [OH^-] = 1.0 \times 10^{-14}$; when $[H^+]$ in a solution increases, the $[OH^-]$ decreases.
19. basic: greater than 7; acidic: less than 7; neutral: 7
20. acid-base indicator or a pH meter
21. $[H^+]$ decreases as pH increases.
22. **a.** 6.0 **b.** 4.00 **c.** 12.0 **d.** 3.0
23. In basic solutions the $[OH^-]$ is greater than $[H^+]$; in acidic solutions $[H^+]$ is greater than $[OH^-]$.
24. **a.** $1.0 \times 10^{-8} M$ **b.** $1.0 \times 10^{-5} M$ **c.** $1.0 \times 10^{-2} M$

Agronomist

Do you like the idea of working with plants but find chemistry more interesting than biology? If so, you might want to consider a career in agronomy. Agronomy is a branch of agriculture that deals with the interactions between plants, soils, and the environment. Agronomists use their knowledge of chemistry to help produce healthy crops and increase yields, while preserving the environment.

The opportunities for agronomists extend beyond laboratories and greenhouses. Agronomists also work for business firms, government agencies, conservation groups, philanthropic organizations, and universities. Agronomists can also use their knowledge of water and land management to address such issues as urban area beautification and highway landscaping.

SOIL ACIDITY The pH of the soil is among the most important factors in crop production. Agronomists can help farmers obtain the right soil pH for a specific crop.

FIELD CHEMISTRY Many agronomists have the opportunity to work with local communities. This agronomist is advising a Kenyan farming group on how to improve their crops using science.

Take It Further

1. **Apply Concepts** The ideal soil pH for corn is around 6.0. If $[H^+]$ equals $2.14 \times 10^{-5} M$, is the soil too acidic or too basic for growing corn?
2. **Infer** What are two nonfood items that an agronomist might help produce?

21st Century Learning To be successful in the 21st century, students need skills and learning experiences that extend beyond subject matter mastery. This project helps students build the following 21st Century Skills: *Creativity and Innovation; Critical Thinking and Problem Solving; Information Literacy; Information, Communication, and Technology Literacy; Initiative and Self-Direction.*

PLAN A GARDEN Pose the following challenge to your students. *You have been hired to plan a garden for a large company. After you complete the following tasks, prepare a three-page report summarizing your plan.*

- Research to find out the typical soil acidity for your area. Which plants will do well in this acidity? Which should you avoid?
- Include a variety of plants. Explain why each plant might do well.
- Include instructions for maintaining the soil pH. What tests should be done? What should be the response to the tests?

START A CONVERSATION Draw students' attention to the photo at the top of the page. Point out that the agronomist is gathering a soil sample to take back to a lab for testing. Pose the following questions. How could the agronomist determine the pH of the soil? What changes might the agronomist recommend if the pH were too high or too low? You may need to guide students in the following ways:.

- Would using an acid-base indicator or a pH meter be more convenient for testing the soil's acidity?
- What could be done to change the soil if it is too acidic? What could be done if the soil is too basic?

Explain

CRITICAL THINKING Lead students in discussing factors that might affect the pH of soil. **Ask** What do you think might contribute to high soil acidity? *(Sample answers: acid rain, the rocks from which the soil formed, fertilizers added to the soil)*

Extend

Connect to BIOLOGY

No single soil pH is best for all plants. Many plants prefer slightly acidic soil, although some prefer slightly basic soil. Explain that different types of nutrients tend to be available to plants in soils with different pH values.

Answers

TAKE IT FURTHER

1. The pH is 4.62, which is probably too acidic for growing corn.
2. Possible answers are cotton, corn that is used to produce ethanol, sod, and pharmaceutical crops, which are harvested for their proteins.

LESSON 19.3

Key Objectives

19.3.1 IDENTIFY the property used to classify acids and bases as strong or weak.

Additional Resources

Reading and Study Workbook, Lesson 19.3

Available Online or on Media:

Engage

CHEMISTRY & YOU Have students study the photograph and read the text that opens the lesson. **Ask** Do you think citric acid is a strong acid or weak acid? *(weak)* **Ask** Do you think sulfuric acid is a strong acid or a weak acid? *(strong)*

Activate Prior Knowledge

Write the ion-product constant (K_w) on the board. **Ask** What does this constant represent? *(the product of the concentrations of hydronium ions and hydroxide ions in water)* **Ask** Why does water contain these ions? *(It undergoes self-ionization.)* Explain that another term used for the process of ionization is *dissociation*. Tell students to keep this term in mind as they read this lesson.

IN ACADEMIC STANDARDS for SCIENCE

C.8.2 Describe the characteristic properties of acids and bases.

C.8.3 Compare and contrast the dissociation and strength of acids and bases in solution.

19.3 Strengths of Acids and Bases

IN **C.8.2** Properties of acids and bases; **C.8.3** Dissociation and strength of acids and bases.

CHEMISTRY & YOU

Q: *What makes one acid safer than another?* Lemon juice, which contains citric acid, has a pH of about 2.3. Yet, you consume lemon juice. When you cut a lemon, you usually don't wear gloves or safety goggles. But some acids do require such precautions. This lesson will explain the difference between a "weak" acid such as citric acid and a "strong" acid such as sulfuric acid.

Key Question

How are acids and bases classified as either strong or weak?

Vocabulary

- strong acid
- weak acid
- acid dissociation constant (K_a)
- strong base
- weak base
- base dissociation constant (K_b)

Strong and Weak Acids and Bases

How are acids and bases classified as either strong or weak?

Table 19.6 compares the strengths of some acids and bases. **Acids and bases are classified as strong or weak based on the degree to which they ionize in water.** Hydrochloric acid and sulfuric acid are examples of strong acids. In general, a **strong acid** is completely ionized in aqueous solution.

$$HCl(g) + H_2O(l) \longrightarrow H_3O^+(aq) + Cl^-(aq) \quad (100\%)$$

A **weak acid** ionizes only slightly in aqueous solution. The ionization of ethanoic acid (CH_3COOH), a typical weak acid, is not complete.

$$CH_3COOH(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + CH_3COO^-(aq) \quad (<1\%)$$

Table 19.6

Relative Strengths of Common Acids and Bases

Substance	Formula	Relative strength
Hydrochloric acid	HCl	Strong acids
Nitric acid	HNO_3	
Sulfuric acid	H_2SO_4	
Phosphoric acid	H_3PO_4	Increasing strength of acid
Ethanoic acid	CH_3COOH	
Carbonic acid	H_2CO_3	
Hypochlorous acid	HClO	
		Neutral solution
Ammonia	NH_3	Increasing strength of base
Sodium silicate	Na_2SiO_3	
Calcium hydroxide	$Ca(OH)_2$	Strong bases
Sodium hydroxide	NaOH	
Potassium hydroxide	KOH	

Focus on ELL

1 CONTENT AND LANGUAGE Assign students to four groups. Assign each group one of the words *strong*, *weak*, *concentrated*, or *diluted*. Have each group complete a Frayer model diagram for the word, with a definition, characteristics, an example and a nonexample. Have each group teach the word to the class.

2 FRONTLOAD THE LESSON Ask students to work with a partner to draw a picture or to cut out magazine pictures that represent the words *strong* and *weak*. Display the results. As students view the display, have them try to deduce what is meant by these two terms in relation to acids and bases.

3 COMPREHENSIBLE INPUT Review the process for writing an equilibrium-constant expression before introducing K_a. Then, demonstrate mathematically that the equation for the dissociation constant (K_a) is achieved by multiplying both sides of the equation by $[H_2O]$. Explain how the $[H_2O]$ values on the right-hand side of the equation cancel each other.

Interpret Graphs

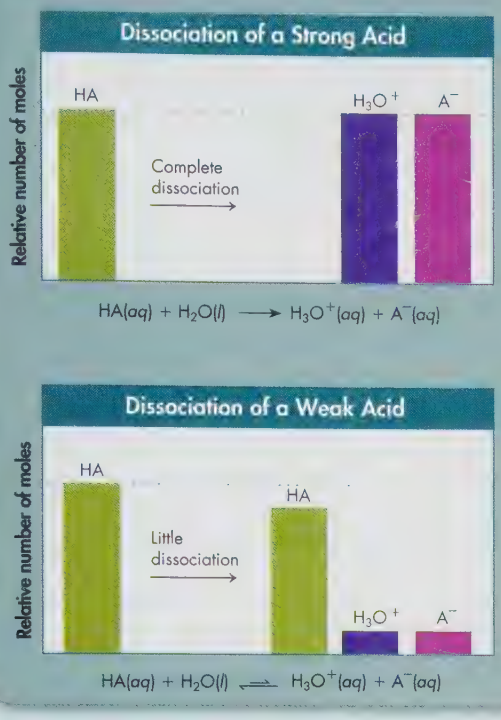

Figure 19.11 Dissociation of an acid (HA) in water yields H_3O^+ and an anion, A^-. The bar graphs compare the extent of dissociation of a strong acid and a weak acid.

a. Explain Why is there only one bar for HA in the graph for the strong acid, but two bars for HA in the graph for the weak acid?

b. Apply Concepts In the graph for the strong acid, why do the bars for H_3O^+ and A^- have the same height as the bar for HA?

c. Infer In the graph for the weak acid, why is the height of the bar for H_3O^+ equal to the distance from the top of the second HA bar to the dotted line?

Hint: The bars represent the relative amounts of the acid and the ions it forms in solution.

Acid Dissociation Constant Figure 19.11 compares the extent of dissociation of strong and weak acids. A strong acid, such as hydrochloric acid, completely dissociates in water. As a result, $[H_3O^+]$ is high in an aqueous solution of a strong acid. By contrast, weak acids remain largely undissociated. For example, in an aqueous solution of ethanoic acid, less than 1 percent of the molecules are ionized at any time.

You can use a balanced equation to write the equilibrium-constant expression for a reaction. The equilibrium-constant expression shown below is for ethanoic acid.

$$K_{eq} = \frac{[H_3O^+] \times [CH_3COO^-]}{[CH_3COOH] \times [H_2O]}$$

For dilute aqueous solutions, the concentration of water is a constant. This constant can be combined with K_{eq} to give an acid dissociation constant. An **acid dissociation constant (K_a)** is the ratio of the concentration of the dissociated form of an acid to the concentration of the undissociated form. The dissociated form includes both the H_3O^+ and the anion.

$$K_{eq} \times [H_2O] = K_a = \frac{[H_3O^+] \times [CH_3COO^-]}{[CH_3COOH]}$$

Differentiated Instruction

LPR LESS PROFICIENT READERS Some students may find the tables and figures overwhelming. Present the visuals on an overhead. During lecture, show only the parts of the visuals necessary for conveying the concept and cover up the rest. Use Socratic questioning to engage students in determining the information provided by each visual.

ELL ENGLISH LANGUAGE LEARNERS At the beginning of the discussion on dissociation constants, provide each student with a sticky note containing the word *dissociation*. During class, clearly pronounce *dissociation (dih so see AY shun)*, and have the class repeat slowly. Then brainstorm a list of synonyms for the word and elicit from students that the antonym of dissociation is *association*.

L1 SPECIAL NEEDS STUDENTS Explain the graph in Figure 19.11 by using a visual and tactile activity. Provide students with stackable colored blocks and help them to create structures similar in height to bars in Figure 19.11. Use Socratic questioning to help students understand how a strong acid differs from a weak acid.

Foundations for Reading

BUILD VOCABULARY Encourage students to create a two-column table, labeling the columns *Acid* and *Base*. Under each column, students should write the related vocabulary words and their definitions.

READING STRATEGY Have students read the key question and then quickly preview the lesson by skimming the headings, visuals, and boldfaced text. Then have students predict the answer to the key question.

Explain

Strong and Weak Acids and Bases

USE VISUALS Have students study Table 19.6. **Ask** Which is the weakest acid in the table? *(hypochlorous acid)* **Ask** Which is the weakest base in the table? *(ammonia)*

CRITICAL THINKING Point out the two equations above Table 19.6. **Ask** What do you notice about the arrows in each equation? *(One equation has a single arrow, and the other equation has a double arrow.)* **Ask** What do these arrows tell you about the degree to which an acid ionizes in water? *(The single arrow pointing to the right indicates that the acid completely ionizes; the double arrow indicates that the acid is not completely ionized.)* Point out the differing lengths of the two arrows. Explain that the shorter length of the top arrow indicates that ionization is occurring but that the preferred direction of the reaction is to the left. **Ask** If there was a greater degree of dissociation occurring, which arrow would be longer—the one for the forward reaction or the one for the reverse reaction? *(The arrow for the forward reaction would be longer.)*

USE VISUALS Direct students to Figure 19.11. Explain to students that the bar graphs compare the extent of ionization or dissociation of strong and weak acids. **Ask** What is the primary difference between strong and weak acids? *(Strong acids are nearly 100% dissociated, whereas weak acids are only partially dissociated.)*

Answers

INTERPRET GRAPHS

a. For a strong acid, there is virtually no HA left after dissociation. For a weak acid, a considerable amount of HA remains after dissociation.

b. The strong acid dissociates completely, forming equal amounts of ions.

c. The amount of acid that dissociates is equal to the amount of each resulting ion.

Explain

Strong and Weak Acids and Bases

APPLY CONCEPTS Remind students that in solution, the negative ion of an acid is a base. Explain that strong acids, such as nitric acid, dissociate almost completely because the negative ion is a very weak base. That is, its tendency to combine with a hydrogen ion is slight. In contrast, the dissociation of a weak acid, such as carbonic acid, is limited, because its negative ion is a relatively strong base. Explain that these ions combine with most of the available hydrogen ions to form the undissociated form of the acid again.

Misconception Alert

The terms *strong* and *weak*, as applied to acids, are often confused with the concept of concentration. Stress that the dissociation of an acid or base into ions involves the establishment of equilibrium. The terms *strong* and *weak* refer to the position of the equilibrium. Explain that when a strong acid or base dissolves, the equilibrium favors the products. However, when a weak acid or base dissolves, the equilibrium favors the reactants. Show students that the extent to which products or reactants are favored can be determined from the values of K_a or K_b. Discuss how values of K_a and K_b can be used to compare the strengths of acids and bases.

USE VISUALS Have students examine Table 19.7. Write out the equation for calculating the first K_a of oxalic acid to reinforce the concept that the K_a for each acid is equal to the product of the concentrations of the products divided by the concentration of the non-ionized acid. Also explain that the K_a value is a quantitative indication of acid strength. A lower K_a value means the reactants are favored in the equilibrium. Thus, the acid is weaker.

CRITICAL THINKING Have students study the dissociation constants for phosphoric acid in Table 19.7. **Ask** What pattern do you observe in the values for K_a? *(Each subsequent* K_a *is smaller than the previous value.)* Explain that as the charge on an acid becomes more negative, its attraction for the remaining protons increases, decreasing the likelihood that additional dissociations will occur to any great degree.

Table 19.7

Dissociation Constants of Weak Acids

Acid	Chemical equation for dissociation	K_a (25°C)
Oxalic acid	$HOOCCOOH(aq) \rightleftharpoons H^+(aq) + HOOCCOO^-(aq)$	5.6×10^{-2}
	$HOOCCOO^-(aq) \rightleftharpoons H^+(aq) + OOCCOO^{2-}(aq)$	5.1×10^{-5}
Phosphoric acid	$H_3PO_4(aq) \rightleftharpoons H^+(aq) + H_2PO_4^-(aq)$	7.5×10^{-3}
	$H_2PO_4^-(aq) \rightleftharpoons H^+(aq) + HPO_4^{2-}(aq)$	6.2×10^{-8}
	$HPO_4^{2-}(aq) \rightleftharpoons H^+(aq) + PO_4^{3-}(aq)$	4.8×10^{-13}
Methanoic acid	$HCOOH(aq) \rightleftharpoons H^+(aq) + HCOO^-(aq)$	1.8×10^{-4}
Benzoic acid	$C_6H_5COOH(aq) \rightleftharpoons H^+(aq) + C_6H_5COO^-(aq)$	6.3×10^{-5}
Ethanoic acid	$CH_3COOH(aq) \rightleftharpoons H^+(aq) + CH_3COO^-(aq)$	1.8×10^{-5}
Carbonic acid	$H_2CO_3(aq) \rightleftharpoons H^+(aq) + HCO_3^-(aq)$	4.3×10^{-7}
	$HCO_3^-(aq) \rightleftharpoons H^+(aq) + CO_3^{2-}(aq)$	4.8×10^{-11}

The acid dissociation constant (K_a) reflects the fraction of an acid that is ionized. For this reason, dissociation constants are sometimes called ionization constants. If the degree of dissociation or ionization of the acid in a solution is small, the value of the dissociation constant will be small. Weak acids have small K_a values. If the degree of ionization of an acid is more complete, the value of K_a will be larger. The stronger an acid is, the larger its K_a value will be. For example, nitrous acid (HNO_2) has a K_a of 4.4×10^{-4}, but ethanoic acid (CH_3COOH) has a K_a of 1.8×10^{-5}. This means that nitrous acid is more ionized in solution than ethanoic acid. Therefore, nitrous acid is a stronger acid than ethanoic acid.

Table 19.7 shows the ionization equations and dissociation constants of a few weak acids. Some of the acids have more than one dissociation constant because they have more than one ionizable hydrogen. Oxalic acid, for example, is a diprotic acid. It loses two hydrogens, one at a time. Therefore, it has two dissociation constants. Oxalic acid is found naturally in certain herbs and vegetables, such as those pictured in Figure 19.12.

The acids in Table 19.7 are ranked by the value of the first dissociation constant. Observe what happens to the K_a with each ionization. The K_a decreases from the first ionization to the second. It decreases again from the second ionization to the third.

Figure 19.12 Oxalic Acid
Chives and parsley have relatively high amounts of oxalic acid compared to other fruits and vegetables.

UbD Check for Understanding

What property is used to classify acids and bases as strong or weak?

Assess students' knowledge about acids and bases by saying that substance X is reported to be a stronger acid than substance Y. **Ask** What information could you use to determine if this statement is true or false? Explain your answer.

(I would compare the dissociation constants for the two acids. A greater K_a *for substance X than for substance Y would show that it is a stronger acid because* K_a *increases as the tendency for an acid to ionize in aqueous solution increases. The stronger the acid, the greater its tendency to ionize in solution.)*

ADJUST INSTRUCTION If students are having trouble answering, have them reread the text following Table 19.7. Then pose the question again.

Calculating Dissociation Constants To calculate the acid dissociation constant (K_a) of a weak acid, you need to know the initial molar concentration of the acid and the $[H^+]$ (or alternatively, the pH) of the solution at equilibrium. You can use these data to find the equilibrium concentrations of the acid and the ions. These values are then substituted into the expression for K_a.

In general, you can find the K_a of an acid in water by substituting the equilibrium concentrations of the acid, [HA], the anion from the dissociation of the acid, $[A^-]$, and the hydrogen ion, $[H^+]$, into the equation below.

$$K_a = \frac{[H^+][A^-]}{[HA]}$$

SampleProblem 19.6

Calculating a Dissociation Constant

In a 0.1000*M* solution of ethanoic acid, $[H^+] = 1.34 \times 10^{-3}M$. Calculate K_a of this acid. Refer to Table 19.7 for the ionization equation for ethanoic acid.

KNOWNS
[ethanoic acid] = 0.1000*M*
$[H^+] = 1.34 \times 10^{-3}M$

UNKNOWN
$K_a = ?$

1 Analyze **List the knowns and the unknown.**

2 Calculate **Solve for the unknown.**

Start by determining the equilibrium concentration of the ions.

$[H^+] = [CH_3COO^-] = 1.34 \times 10^{-3}M$

Each molecule of CH_3COOH that ionizes gives an H^+ ion and a CH_3COO^- ion.

Then determine the equilibrium concentrations of each component.

$(0.1000 - 0.00134)M = 0.0987M$

Concentration	$[CH_3COOH]$	$[H^+]$	$[CH_3COO^-]$
Initial	0.1000	0	0
Change	-1.34×10^{-3}	1.34×10^{-3}	1.34×10^{-3}
Equilibrium	0.0987	1.34×10^{-3}	1.34×10^{-3}

Substitute the equilibrium values into the expression for K_a.

$$K_a = \frac{[H^+] \times [CH_3COO^-]}{[CH_3COOH]} = \frac{(1.34 \times 10^{-3}) \times (1.34 \times 10^{-3})}{0.0987}$$

$$= 1.82 \times 10^{-5}$$

3 Evaluate **Does the result make sense?** The calculated value of K_a is consistent with that of a weak acid.

25. In a 0.1000*M* solution of methanoic acid, $[H^+] = 4.2 \times 10^{-3}M$. Calculate the K_a of this acid.

26. In a 0.2000*M* solution of a monoprotic weak acid, $[H^+] = 9.86 \times 10^{-4}M$. What is the K_a for this acid?

Foundations for Math

ASSOCIATIVE PROPERTY AND SCIENTIFIC NOTATION Explain that in multiplication of numbers written in scientific notation, numbers can be regrouped using the Associative Property of Multiplication: $(xy)(xz) = (xx)(yz)$.

In the last step of **Sample Problem 19.6,** show students how to regroup the two factors written in scientific notation in the numerator of the fraction:

$$(1.34 \times 10^{-3})(1.34 \times 10^{-3}) = (1.34 \times 1.34)(10^{-3} \times 10^{-3})$$

Next, group the decimals and group the powers:

$$= 1.34^{1+1} \times 10^{-3+(-3)}$$

Then have students use exponent rules to find the product:

$$= 1.34^2 \times 10^{-6} = 1.80 \times 10^{-5}$$

Explain

APPLY CONCEPTS Explain how the dissociation constant of an acid or base can be determined experimentally from the concentration of the solution and its pH. Tell students that the calculation is based on the assumption that the acid molecule forms an equal number of hydrogen ions and negative ions when it dissociates. Explain that this is true only if there is no additional source of either hydrogen ions or the negative ions.

Tell students that the process of calculating experimental dissociation constants is more complicated in the case of polyprotic acids, because there are multiple equilibrium reactions taking place simultaneously and they each influence the others. With polyprotic acids, all of the reactions will produce H_3O^+ but in differing amounts. The scientist must make assumptions about the relative amounts of H_3O^+ contributed by each reaction. Also, the products of some reactions are reactants in others, so the net change in their concentrations must be taken into account. Explain that for this course, students will only be expected to calculate dissociation constants for monoprotic acids.

Sample Practice Problem

A solution of a weak acid, which is exactly 0.725*M*, has a $[H^+] = 5.23 \times 10^{-6}M$.

a. What is the pH of this solution? *(5.292)*

b. What is the value of K_a for this acid? *(3.77×10^{-11})*

Answers

SAMPLE PROBLEM 19.6

25. $K_a = 1.8 \times 10^{-4}$

26. $K_a = 4.89 \times 10^{-6}$

Extend

Ask for a show of hands of students who have heard the phrase *pH-balanced shampoo*. Explain that healthy hair has a pH range of 4.5 to 5.5 and that alkaline shampoos can damage the cuticle of hairs. Divide the class into small groups to research the types of shampoo ingredients and their uses. Then, provide a selection of shampoos for normal, dry, and oily hair for students to test. Have students conduct a survey of ingredients and pH levels for the different shampoos and present their results. Supply each group with a 10-mL graduated cylinder, universal indicator paper, and beakers. Suggest that students prepare standard 1% solutions of shampoo for testing pH. Have groups present their findings to the class.

Connect to ENVIRONMENTAL SCIENCE

Have students do research about the sources and causes of acid rain. *(Acid rain is thought to be due principally to the release of sulfur oxides and nitrogen oxides into the atmosphere.)* **Ask** How do weather patterns affect the distribution of environmental damage due to acid rain? *(Prevailing winds generally carry pollutants from west to east.)* **Ask** What types of vegetation, if any, are most resistant to acid rain or tend to thrive in acidic soils? *(Students may wish to speak to staff at nurseries for help in answering this question.)* **Ask** What types of conservation efforts are used to adjust the pH of lakes and rivers that become too acidic? *(A special slurry of $CaCO_3$, or limestone, is sometimes added to lakes and rivers to control pH.)*

Figure 19.13 Use of Ammonia Window cleaners often use a solution of ammonia in water to clean glass.
Explain *Why is this solution relatively safe to use?*

Base Dissociation Constant Just as there are strong acids and weak acids, there are strong bases and weak bases. A **strong base** dissociates completely into metal ions and hydroxide ions in aqueous solution. Some strong bases, such as calcium hydroxide and magnesium hydroxide, are not very soluble in water. The small amounts of these bases that dissolve in water dissociate completely.

A **weak base** reacts with water to form the conjugate acid of the base and hydroxide ions. For a weak base, the amount of dissociation is relatively small. Ammonia is an example of a weak base. One use for an aqueous solution of ammonia is shown in Figure 19.13.

$$\underset{\text{Ammonia}}{NH_3(aq)} + \underset{\text{Water}}{H_2O(l)} \rightleftharpoons \underset{\text{Ammonium ion}}{NH_4^+(aq)} + \underset{\text{Hydroxide ion}}{OH^-(aq)}$$

When equilibrium is established, only about 1 percent of the ammonia is present as NH_4^+. This ion is the conjugate acid of NH_3. The concentrations of NH_4^+ and OH^- are low and equal. The equilibrium-constant expression for the dissociation of ammonia in water is as follows:

$$K_{eq} = \frac{[NH_4^+] \times [OH^-]}{[NH_3] \times [H_2O]}$$

Recall that the concentration of water is constant in dilute solutions. This constant can be combined with the K_{eq} for ammonia to give a base dissociation constant (K_b) for ammonia.

$$K_{eq} \times [H_2O] = K_b = \frac{[NH_4^+] \times [OH^-]}{[NH_3]}$$

In general, the **base dissociation constant (K_b)** is the ratio of the concentration of the conjugate acid times the concentration of the hydroxide ion to the concentration of the base. The general form of the expression for the base dissociation constant is shown below.

$$K_b = \frac{[\text{conjugate acid}] \times [OH^-]}{[\text{base}]}$$

You can use this equation to calculate the K_b of a weak base. You need to know the initial concentration of the base and the concentration of hydroxide ions at equilibrium. If you know the pH, you can calculate $[H^+]$ and the corresponding $[OH^-]$.

The magnitude of K_b indicates the ability of a weak base to compete with the very strong base OH^- for hydrogen ions. Because bases such as ammonia are weak relative to the hydroxide ion, the K_b for such a base is usually small. The K_b for ammonia is 1.8×10^{-5}. The smaller the value of K_b, the weaker the base.

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the Small-Scale Lab on page 670. Make sure each group has ELLs of varied language proficiencies so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Have students use colored pencils or crayons to draw pictures of their observations.

INTERMEDIATE: LOW/HIGH Provide students with a chart they can use to record their observations.

ADVANCED: LOW/HIGH Have students assist students with lower English proficiencies with the calculations and answering the questions.

Table 19.8

Comparing Concentration and Strength of Acids

Acidic solution	Concentration		Strength
	Quantitative [or Molar]	Relative	
Hydrochloric acid	12M HCl	Concentrated	Strong
Gastric juice	0.08M HCl	Dilute	Strong
Ethanoic acid	17M CH_3COOH	Concentrated	Weak
Vinegar	0.2M CH_3COOH	Dilute	Weak

CHEMISTRY & YOU

Q: *Despite its relatively low pH, lemon juice is safe to consume because citric acid is a weak acid. Citric acid has three K_a values. What does this information tell you about citric acid?*

Concentration Versus Strength Sometimes people confuse the concepts of concentration and strength. The words *concentrated* and *dilute* indicate how much of an acid or base is dissolved in solution. These terms refer to the number of moles of the acid or base in a given volume. The words *strong* and *weak* refer to the extent of ionization or dissociation of an acid or base.

Table 19.8 shows four possible combinations of concentration and strength for acids. Hydrochloric acid, HCl(*aq*), is a strong acid because it completely dissociates into ions. The gastric juice in your stomach is a dilute solution of HCl. The relatively small number of HCl molecules in a given volume of gastric juice are all dissociated into ions. To summarize, even when concentrated hydrochloric acid is diluted with water, it is still a strong acid. Conversely, ethanoic acid (acetic acid) is a weak acid because it ionizes only slightly in solution. Vinegar is a dilute solution of ethanoic acid. Even at a high concentration, ethanoic acid is still a weak acid.

The same concepts apply to bases. A solution of ammonia can be either dilute or concentrated. However, in any solution of ammonia, the relative amount of ionization will be small. Thus, ammonia is a weak base at any concentration. Likewise, sodium hydroxide is a strong base at any concentration.

19.3 LessonCheck

27. Review What factor determines whether an acid or base is strong or weak?

28. Compare How do acid dissociation constants vary between strong acids and weak acids?

29. Draw Conclusions Which of the acids in Table 19.6 would you expect to have the lowest dissociation constant?

30. Describe How do you determine the K_a of a weak acid or the K_b of a weak base?

31. Predict Acid HX has a very small K_a. How will the relative amounts of H^+ and HX compare at equilibrium?

32. Calculate A 0.500*M* solution of an acid has a hydronium-ion concentration of $5.77 \times 10^{-6}M$. Calculate the K_a of this acid.

33. Describe Write a chemical equation for the dissociation of each of the following acids and bases in water.

a. nitric acid

b. ethanoic acid

c. ammonia

d. magnesium hydroxide

34. Classify A 15*M* solution of an acid has a K_a of 7.5×10^{-3}. Explain how you would classify this solution in terms of concentration and strength.

Lesson Check Answers

27. the degree to which they ionize in water

28. A strong acid is completely ionized in aqueous solution and has a large K_a. A weak acid ionizes only slightly in aqueous solution and has a small K_a.

29. hypochlorous acid

30 Substitute the measured concentrations of all the substances present at equilibrium into the expressions for K_a or K_b.

31. [HA] will be much greater than $[H^+]$ at equilibrium.

32. $K_a = 6.66 \times 10^{-11}$.

33. a. $HNO_3 + H_2O \rightarrow H_3O + NO_3^-$

b. $CH_3COOH + H_2O \rightleftharpoons CH_3COO^- + H_3O^+$

c. $NH_3 + H_2O \rightleftharpoons NH_4^+ + H_2O$

d. $Mg(OH)_2 \rightarrow Mg^2 + 2OH^-$

34. It is concentrated based on its molarity, but weak based on its K_a.

CHEMISTRY & YOU The fact that citric acid has three acid dissociation constants indicates that citric acid is a triprotic acid.

Evaluate

Informal Assessment

Direct students to write or state the two conditions needed to calculate the dissociation constant of a weak acid. *(You must know the initial molar concentration of the acid and the pH or $[H^+]$ of the solution at equilibrium.)* Then direct students to complete the 19.3 Lesson Check.

Reteach

Place students in small groups. Have each group prepare a numbered list of steps for calculating dissociation constants. Have groups share their lists with the class. Create an overall class list of steps to follow for calculating dissociation constants. Provide a problem similar to Sample Problem 19.6, and have students use the class-generated procedure to work through the problem.

Small-Scale Lab

Dissociation Constants of Weak Acids

Purpose

To measure dissociation constants of weak acids

Materials

- paper, pencil, and ruler
- reaction surface
- 12 solutions with different pH values
- bromocresol green
- solutions of other acid-base indicators

Procedure

1. On two separate sheets of paper, draw two grids similar to the one below. Make each square 2 cm on each side.

2. Place a reaction surface over one of the grids and place one drop of bromocresol green in each square.

3. Add one drop of the solution with a pH of 1 to the square labeled 1. Add one drop of the solution with a pH of 2 to the square labeled 2. Continue adding drops in this manner until you have added a drop to each square.

4. Use the second grid as a data table to record your observations for each square.

pH

1	2	3
4	5	6
7	8	9
10	11	12

Analyze and Conclude

1. Observe What colors are the solutions with the lowest pH and the highest pH?

2. Observe At which pH does the bromocresol green change from one color to the other?

3. Infer Acid-base indicators, such as bromocresol green, are usually weak acids. Because bromocresol green has a fairly complex formula, it is convenient to represent its formula as HBCG. HBCG dissociates in water according to the following equation. HBCG and BCG^- are a conjugate acid-base pair.

$$\underset{\text{(yellow)}}{HBCG(aq)} + H_2O(l) \rightleftharpoons \underset{\text{(blue)}}{BCG^-(aq)} + H_3O^+(aq)$$

The K_a expression is

$$K_a = \frac{[BCG^-] \times [H_3O^+]}{[HBCG]}$$

When $[BCG^-] = [HBCG]$, $K_a = [H_3O^+]$.

What color is the conjugate base of HBCG? What color is the conjugate acid of BCG^-?

4. Draw Conclusions At what pH is there an equal amount of the conjugate acid and conjugate base? How can you tell?

5. Calculate What is the K_a for the solution described in Question 4?

You're the Chemist

1. Design an Experiment Design and carry out an experiment to measure the dissociation constants of some other acid-base indicators. Record the color of each conjugate acid and conjugate base. Calculate the K_a for each acid.

2. Explain How can you measure the dissociation constant of an acid-base indicator? Describe what to do and how to interpret the results.

ANALYZE AND CONCLUDE

1. THe lowest pH solutions are yellow and the highest pH solutions are blue.
2. pH 4
3. The conjugate acid, HBCG, is yellow. The conjugate base, BCG^-, is blue.
4. at pH 4, because the indicator is green
5. 1.0×10^{-4}

YOU'RE THE CHEMIST

1. Results will vary depending on the indicators chosen.
2. To measure the K_a of a colored acid-base indicator, mix one drop of the indicator solution with one drop of each pH 1–12 buffer solution. Look for the pH of the color change. This pH is close to the K_a of the acid.

Stone Erosion

All around the world, famous stone structures such as the Parthenon in Greece, the Taj Mahal in India, the Mayan carvings in Mexico, and the gargoyles on the facade of the Notre Dame Cathedral are slowly being eroded by acid rain.

Acid rain is rain with a pH of 5.0 or less. It forms when airborne pollutants, namely sulfur dioxide and nitrogen oxides, combine with water vapor in the atmosphere to produce acids.

Many famous buildings, statues, and landmarks are made of marble or limestone. Both of these materials consist of calcium carbonate, $CaCO_3$. The acids in acid rain react with the calcium carbonate in the stones to form calcium ions, water, and carbon dioxide. In this process, the intricate detail of the structure is lost. Explore for yourself how acids affect materials made of calcium carbonate by trying the activity below.

On Your Own

1. For this activity you will need **2 bowls, 2 same-size pieces of chalk made of calcium carbonate, white vinegar, tap water, masking tape, a permanent marker,** and **a paper towel.** Put vinegar in the first bowl. Label the bowl with a piece of masking tape and a marker. Put the same amount of water in the second bowl and label it. *Optional*: If you'd like, you can scratch a design (with a needle, nail, or thumb tack) into each piece of chalk before going to Step 2.

2. Place a piece of chalk in each bowl. Observe what happens to the chalk.

3. After about 5 minutes, remove the chalk pieces from the bowls and place the pieces on a paper towel. Compare the pieces of chalk.

Think About It

1. Compare How did the vinegar affect the chalk compared to the water?

2. Infer What causes the bubbles you see when the chalk is placed in vinegar?

3. Describe Write a balanced equation to explain what happens to the chalk when it is placed in vinegar. *Note*: Let $H^+(aq)$ represent the acid.

4. Draw Conclusions Why does acid rain result in a loss of detail in the gargoyle above? What would be the effect of acid rain on a statue over a long period of time?

Differentiated Instruction

L1 STRUGGLING STUDENTS Have students perform the activity with a partner. Discuss the questions as a class.

LPR LESS PROFICIENT READERS Have students make a list of difficult words in the feature, and discuss their meanings. Lead students in summarizing the feature before they perform the activity.

L3 ADVANCED STUDENTS Have students test several rocks for the presence of calcium carbonate. They should research the procedure and the types of rocks to test.

CHEMISTRY & YOU Draw students' attention to the statue in the picture. Point out the pitted stone and the discoloration on the statue's face and neck. Ask students if they have seem similar damage to stone structures in your community and, if so, to describe the damage.

Explain

CRITICAL THINKING Nitric acid and sulfuric acid are chemicals in air that can produce acid rain. Ask How would the concentration of these chemicals in air affect the pH of rain? *(Because these chemicals can combine with water vapor to form acids, an increase in concentration should cause a decrease in pH.)*

Answers

THINK ABOUT IT

1. The vinegar had a much more noticeable effect on the chalk.
2. The reaction between the acid in vinegar and the calcium carbonate in chalk produced carbon dioxide.
3. $2H^+ + CaCO_3 \rightarrow Ca^{2+} + H_2O + CO_2$
4. *Sample answer*: The acid reacts with and erodes those parts of the stone that project out from the surface. With time fewer and fewer of the original details remain.

LESSON 19.4

Key Objectives

19.4.1 DEFINE the products that form when an acid and a base react.

19.4.2 IDENTIFY the point in a titration when neutralization will occur.

Additional Resources

Reading and Study Workbook, Lesson 19.4

Available Online or on Digital Media:

Engage

CHEMISTRY & YOU Have students read the opening text and study the photograph. Tell students that adding iron to soil with a high pH will not reverse chlorosis. Ask students to hypothesize what role soil pH might play in the availability of iron to plants.

Activate Prior Knowledge

Have students review what they know about acid-base indicators. Direct students to examine Figures 19.8 and 19.9 as a prelude to discussing titration.

Foundations for Reading

BUILD VOCABULARY Have students write *standard solution, titration,* and *end point* in the first column of a three-column chart. In the second column, they should write each term's definition. Have students use the third column to explain how each term is related to the others.

IN ACADEMIC STANDARDS for SCIENCE

C.8.2 Describe the characteristic properties of acids and bases.

C.8.5 For an acid-base titration, calculate the concentration of an unknown solution.

19.4 Neutralization Reactions

C.8.2 Properties of acids and bases; C.8.5 Titration calculations.

CHEMISTRY & YOU

Q: *What could cause leaves to turn yellow during the growing season?* You may have noticed yellow leaves like these during a season when the leaves should still be green. This condition is called *chlorosis* because the plant lacks a pigment called chlorophyll. To produce chlorophyll, plants need to absorb nutrients, such as iron, from the soil. Sometimes there is plenty of iron, but it is not taken up by the roots of the plant because the pH of the soil is too high.

Key Questions

What products form when an acid and a base react?

At what point in a titration does neutralization occur?

Vocabulary

- neutralization reaction
- titration
- standard solution
- equivalence point
- end point

Acid-Base Reactions

What products form when an acid and a base react?

Suppose you mix a solution of a strong acid, such as HCl, with a solution of a strong base, such as NaOH. The products are sodium chloride and water.

$$HCl(aq) + NaOH(aq) \longrightarrow NaCl(aq) + H_2O(l)$$

In general, acids and bases react to produce a salt and water. The complete reaction of a strong acid and a strong base produces a neutral solution. Thus, this type of reaction is called a **neutralization reaction.**

When you hear the word *salt,* you may think of the substance that is used to flavor food. Table salt (NaCl) is only one example of a salt. Salts are ionic compounds consisting of an anion from an acid and a cation from a base.

A reaction between an acid and base will go to completion when the solutions contain equal numbers of hydrogen ions and hydroxide ions. The balanced equation provides the correct ratio of acid to base. For hydrochloric acid and sodium hydroxide, the mole ratio is 1:1.

$$\underset{1\ mol}{HCl(aq)} + \underset{1\ mol}{NaOH(aq)} \longrightarrow \underset{1\ mol}{NaCl(aq)} + \underset{1\ mol}{H_2O(l)}$$

For sulfuric acid and sodium hydroxide, the ratio is 1:2. Two moles of the base are required to neutralize one mole of the acid.

$$\underset{1\ mol}{H_2SO_4(aq)} + \underset{2\ mol}{2NaOH(aq)} \longrightarrow \underset{1\ mol}{Na_2SO_4(aq)} + \underset{2\ mol}{2H_2O(l)}$$

Similarly, hydrochloric acid and calcium hydroxide react in a 2:1 ratio.

$$\underset{2\ mol}{2HCl(aq)} + \underset{1\ mol}{Ca(OH)_2(aq)} \longrightarrow \underset{1\ mol}{CaCl_2(aq)} + \underset{2\ mol}{2H_2O(l)}$$

Learn more about acid-base reactions online.

Focus on ELL

1 CONTENT AND LANGUAGE Begin the lesson by writing the words *neutralization* and *titration* on the board. Pronounce each word slowly and have students repeat. Write various forms of each word. As a class, discuss other contexts where students have seen or studied the term *neutral*. Explain that the word *titration* stems from the French word *titre*, meaning "to rank." Have students predict how *neutralization* and *titration* are related in the study of acids and bases.

2 FRONTLOAD THE LESSON Have students participate in a Think-Pair-Share exercise to share personal or academic experiences with neutralization and titration.

3 COMPREHENSIBLE INPUT During the teacher demonstrations, use the think-aloud strategy by stopping intermittently during the demonstrations and explaining your thought process. During the titration, point out that a momentary color change at the point of drop impact signals that the end point of the titration is near.

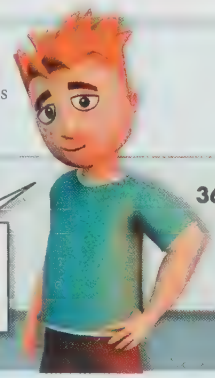
Sample Problem 19.7

Finding the Moles Needed for Neutralization

The term *neutralization* is used to describe both the reaction and the point at which a neutralization reaction is complete. How many moles of sulfuric acid are required to neutralize 0.50 mol of sodium hydroxide? The equation for the reaction is

$$H_2SO_4(aq) + 2NaOH(aq) \longrightarrow Na_2SO_4(aq) + 2H_2O(l)$$

1 Analyze **List the knowns and the unknown.** To determine the number of moles of acid, you need to know the number of moles of base and the mole ratio of acid to base.



KNOWNS	UNKNOWN
mol NaOH = 0.50 mol	mol H_2SO_4 = ? mol
1 mol H_2SO_4/2 mol NaOH (from balanced equation)	

2 Calculate **Solve for the unknown.**

Use the mole ratio of acid to base to determine the number of moles of acid.

$$0.50 \text{ mol NaOH} \times \frac{1 \text{ mol } H_2SO_4}{2 \text{ mol NaOH}} = 0.25 \text{ mol } H_2SO_4$$

3 Evaluate **Does the result make sense?** Because the mole ratio of H_2SO_4 to NaOH is 1:2, the number of moles of H_2SO_4 should be half the number of moles of NaOH.

To solve each problem, begin by writing a balanced equation.

35. How many moles of potassium hydroxide are needed to neutralize 1.56 mol of phosphoric acid?

36. How many moles of sodium hydroxide are required to neutralize 0.20 mol of nitric acid?

Titration

At what point in a titration does neutralization occur?

You can use a neutralization reaction to determine the concentration of an acid or base. The process of adding a measured amount of a solution of known concentration to a solution of unknown concentration is called a **titration.** The steps in an acid-base titration are as follows.

1. A measured volume of an acid solution of unknown concentration is added to a flask.
2. Several drops of an indicator are added to the solution while the flask is gently swirled.
3. Measured volumes of a base of known concentration are mixed into the acid until the indicator just barely changes color.

Foundations for Math

DECIMALS Explain that students can convert between equivalent decimals and fractions when solving problems. Either number form will lead them to the correct answer as long as they complete the dimensional analysis correctly.

In **Sample Problem 19.7,** show students that the moles of sodium hydroxide, 0.50 mol, is equivalent to 50 one-hundredths, or 50/100. Then show the conversion problem as follows. Have students complete the problem without the use of a calculator.

$$\frac{50 \text{ mol NaOH}}{100} \times \frac{1 \text{ mol } H_2SO_4}{2 \text{ mol NaOH}} = \frac{50 \text{ mol } H_2SO_4}{200} = \frac{1}{4} \text{ mol } H_2SO_4 = 0.25 \text{ mol } H_2SO_4.$$

READING STRATEGY Have students skim through the text to identify and list unfamiliar words before reading for content. Help students use context clues to deduce the meaning of these words. Have students write the definition of each of these words on a sticky note and place it at point of use for reference.

Explain

Acid-Base Reactions

MAKING CONNECTIONS Ask students if they have witnessed or read a news report about a chemical spill on a highway or at a factory. **Ask** If a spill involves an acid, what type of treatment is possible? *(A weak base in powder form, such as sodium carbonate, can be spread over the spill to absorb, react with, and neutralize the acid.)*

Sample Practice Problem

How many moles of aluminum hydroxide are needed to neutralize 2.30 mol of sulfuric acid? *(1.53 mol)*

APPLY CONCEPTS Point out that neutralization is a process that occurs whenever an acid reacts with a base in the mole ratios specified by the balanced equation. Explain that not all neutralization reactions produce neutral solutions. The relative strengths of the reactants determine whether the solution will be acidic, basic, or neutral.

Extend

Explain that curling hair with a permanent wave process involves an acid-base neutralization reaction. Pass around pictures or use a student volunteer to convey what a permanent wave looks like. Explain that a permanent wave process involves rolling the hair with curlers, applying a waving solution, rinsing with water, then finally applying a neutralizing solution. Have students research the chemistry behind this hair treatment process. Have students report back to the class on their findings. *(Students should discover that the waving solution is basic with a pH ≈ 9.2, and the neutralizer is acidic with a pH range of 2 to 6. The typical active ingredient in the waving solution is an ammonium compound, and prolonged exposure to this compound before neutralization can result in damaged hair.)*

SAMPLE PROBLEM 19.7

35. 4.68 mol KOH
36. 0.20 mol NaOH

Explore

Titration

Teacher Demo

PURPOSE Students will observe properties of titration using indicators.

MATERIALS equimolar solutions of HCl and NaOH, phenolphthalein, electric stirrer with a magnetic stir bar (if available), beaker, table salt

SAFETY Wear goggles and laboratory apron.

PROCEDURE Write the following equation on the board: $HCl(aq) + NaOH(aq) \rightarrow NaCl(aq) + H_2O(l)$

Prepare equimolar solutions of HCl and NaOH. Add a few drops of phenolphthalein indicator to the NaOH solution. Slowly add the HCl to the NaOH while carefully stirring. If possible, use an electric stirrer with a magnetic stir bar. **Ask** What happens to the color of the solution as the acid is added? *(The deep pink color slowly fades until the solution becomes colorless.)* Remind students that phenolphthalein is an acid-base indicator that is colorless at pH lower than 8. Have a few volunteers come up and gently touch the outside of the reaction beaker. Have students describe their observations to the class. **Ask** Is the neutralization reaction endothermic or exothermic? *(exothermic)*

Display a quantity of table salt equivalent to the amount of salt that could be retrieved if the neutral solution were evaporated.

EXTENSION Repeat the demo, placing the base in a beaker and the acid in a buret. Use a pH meter to monitor the titration. Construct a graph similar to the one in Figure 19.15. Compared with Figure 19.15, the graph will be reversed because an acidic solution is being added to a basic solution. **Ask** What happens to the graph as the titration nears its equivalence point? *(The slope becomes very steep.)* **Ask** What would happen to the pH if a small amount of base were added to the beaker after the equivalence point is reached? *(The pH would increase dramatically.)*

Add some base to the beaker and observe the pH. **Ask** What can be done to regain the equivalence point? *(Add acid from the buret.)*

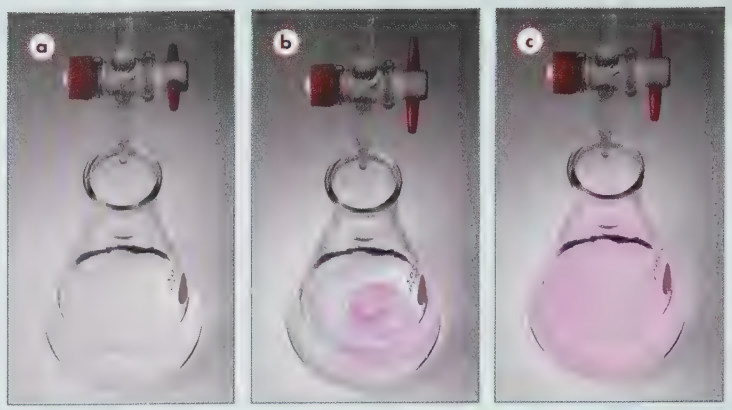

Figure 19.14 Titration
The photographs show steps in an acid-base titration. **a.** A flask with a known volume of acid (and some phenolphthalein indicator) is placed beneath a buret that is filled with a base of known concentration. **b.** Base is slowly added from the buret to the acid while the flask is gently swirled. **c.** A change in the color of the solution is the signal that neutralization has occurred.

The solution of known concentration is the **standard solution.** The steps in the titration of an acid of unknown concentration with a standard base are shown in Figure 19.14. You can use a similar procedure to find the concentration of a base using a standard acid.

Neutralization occurs when the number of moles of hydrogen ions is equal to the number of moles of hydroxide ions. Two things that are equal in value are said to be *equivalent.* Thus, the point at which neutralization occurs is called the **equivalence point.** The indicator that is chosen for a titration must change color at or near the pH of the equivalence point. The point at which the indicator changes color is the **end point** of the titration.

Figure 19.15 shows how the pH of a solution changes during the titration of a strong acid (HCl) with a strong base (NaOH). The initial acid solution has a low pH (about 1). As NaOH is added, the pH increases because some of the acid reacts with the base. The equivalence point for this reaction occurs at a pH of 7. As the titration nears the equivalence point, the pH rises dramatically because hydrogen ions are being used up. Extending the titration beyond the point of neutralization produces a further increase of pH. If the titration of HCl and NaOH could be stopped right at the equivalence point, the solution in the beaker would consist of only H_2O and NaCl, plus a small amount of indicator.

CHEMISTRY & YOU

Q: *Iron compounds need to dissociate before the iron can be absorbed by plants. However, these compounds become less soluble as the pH rises. For most plants, a pH between 5.0 and 6.5 will provide enough usable iron. How could you change the pH of soil?*

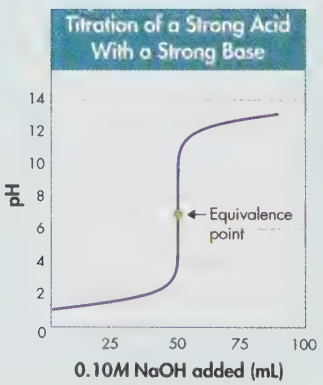

Figure 19.15 Titration Curve
In this titration, 0.10*M* NaOH is slowly added to 50.0 mL of 0.10*M* HCl. The pH of the solution is measured and recorded periodically to construct a titration curve. The equivalence point is located at the midpoint of the vertical part of the curve. Neutralization occurs when 50.0 mL of NaOH have been added to the flask.
Compare ***How are $[H^+]$ and $[OH^-]$ related at the equivalence point?***

UbD Check for Understanding

The Essential Question **What happens when acids and bases react?**

Assess students' understanding of the events that occur when an acid and base react by asking students to briefly explain what occurs during a neutralization reaction. *(In a neutralization reaction, an acid and a base react to form a salt and water, and the reaction is considered to have gone to completion when there are equal numbers of hydrogen ions and hydroxide ions in solution)*

ADJUST INSTRUCTION If students have difficulty answering, review the Titration section. Be sure students recognize that achieving an equal number of hydrogen ions and hydroxide ions at neutralization is not synonymous with a 1:1 mole ratio between acid and base, as is demonstrated by the mole ratio between hydrochloric acid and calcium hydroxide.

Sample Problem 19.8

Determining Concentration by Titration

A 25-mL solution of H_2SO_4 is neutralized by 18 mL of 1.0*M* NaOH. What is the concentration of the H_2SO_4 solution? The equation for the reaction is

$$H_2SO_4(aq) + 2NaOH(aq) \longrightarrow Na_2SO_4(aq) + 2H_2O(l)$$

KNOWNS

$[NaOH] = 1.0M$

$V_{NaOH} = 18\ mL = 0.018\ L$

$V_{H_2SO_4} = 25\ mL = 0.025\ L$

UNKNOWN

$[H_2SO_4] = ?M$

1 Analyze **List the knowns and the unknown.** The conversion steps are as follows: L NaOH ⟶ mol NaOH ⟶ mol H_2SO_4 ⟶ *M* H_2SO_4.

2 Calculate **Solve for the unknown.**

Convert volumes to liters because molarity is in moles per liter.

Use the molarity to convert the volume of base to moles of base.

$$0.018\ \text{L NaOH} \times \frac{1.0\ \text{mol NaOH}}{1\ \text{L NaOH}} = 0.018\ \text{mol NaOH}$$

Use the mole ratio to find the moles of acid.

$$0.018\ \text{mol NaOH} \times \frac{1\ \text{mol } H_2SO_4}{2\ \text{mol NaOH}} = 0.0090\ \text{mol } H_2SO_4$$

Calculate the molarity by dividing moles of acid by liters of solution.

$$\text{molarity} = \frac{\text{mol of solute}}{\text{L of solution}} = \frac{0.0090\ \text{mol}}{0.025\ \text{L}} = 0.36M\ H_2SO_4$$

3 Evaluate **Does the result make sense?** If the acid had the same molarity as the base (1.0*M*), 50 mL of base would neutralize 25 mL of acid. Because the volume of base is much less than 50 mL, the molarity of the acid must be much less than 1.0*M*.

37. How many milliliters of 0.45*M* HCl will neutralize 25.0 mL of 1.00*M* KOH?

38. What is the molarity of a solution of H_3PO_4 if 15.0 mL is neutralized by 38.5 mL of 0.150*M* NaOH?

19.4 LessonCheck

39. Review What are the products of a reaction between an acid and a base?

40. Explain Why is the point in the titration when neutralization occurs called the equivalence point?

41. Calculate How many moles of HCl are required to neutralize aqueous solutions of these bases?

a. 0.03 mol KOH

b. 2 mol NH_3

c. 0.1 mol $Ca(OH)_2$

42. Describe Write complete balanced equations for the following acid-base reactions:

a. $H_2SO_4(aq) + KOH(aq) \longrightarrow$

C.8.2 Properties of acids and bases.

CHEMISTRY & YOU

Q: *How is the pH of blood controlled in the human body?* Chemical reactions in cells are very sensitive to slight changes in pH. For example, the pH of human blood needs to be kept close to 7.4. A person cannot survive for more than a few minutes if the pH of blood drops below 6.8 or rises above 7.8. This lesson will explain the process that prevents such a life-threatening event.

Key Questions

- ***When is the solution of a salt acidic or basic?***
- ***What are the components of a buffer?***

Vocabulary

- salt hydrolysis
- buffer
- buffer capacity

Salt Hydrolysis

When is the solution of a salt acidic or basic?

Recall that a salt is one of the products of a neutralization reaction. A salt consists of an anion from an acid and a cation from a base. The solutions of many salts are neutral. Salts that form neutral solutions include sodium chloride and potassium sulfate. Some salts form acidic or basic solutions, as shown in Figure 19.16. The indicator used for Figure 19.16 is called universal indicator because it can be used for a wide range of pH values.

Figure 19.17 shows two titration curves. One curve is for the addition of sodium hydroxide, a strong base, to ethanoic acid, a weak acid. An aqueous solution of sodium ethanoate exists at the equivalence point.

$$\underset{\text{Ethanoic acid}}{CH_3COOH(aq)} + \underset{\text{Sodium hydroxide}}{NaOH(aq)} \longrightarrow \underset{\text{Sodium ethanoate}}{CH_3COONa(aq)} + \underset{\text{Water}}{H_2O(l)}$$

The second titration curve is for the reaction between hydrochloric acid, which is a strong acid, and sodium hydroxide. This second curve should look familiar. It first appeared in Lesson 19.4 in the section on titrations.

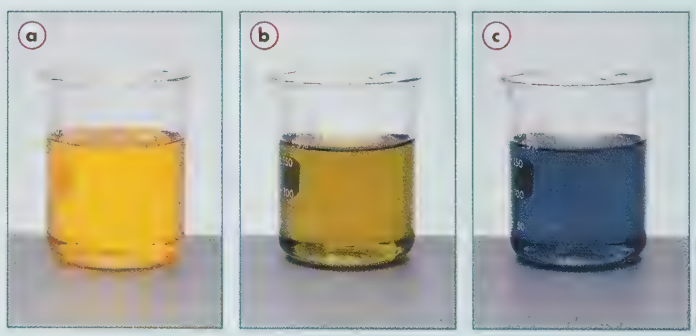

Figure 19.16
The pH of Salt Solutions
Universal indicator was added to 0.10*M* aqueous salt solutions. Based on the indicator color, the solutions can be classified as follows: **a.** Ammonium chloride, $NH_4Cl(aq)$, is acidic (pH of about 5.3). **b.** Sodium chloride, $NaCl(aq)$, is neutral (pH of 7). **c.** Sodium ethanoate, $CH_3COONa(aq)$, is basic (pH of about 8.7).

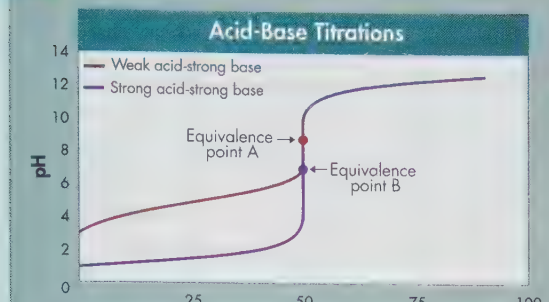
Focus on ELL

1 CONTENT AND LANGUAGE Write the word *buffer* on the board and say it out loud. Explain that this word has both common and scientific meanings. One of the common meanings is "something that provides a protective barrier." Explain that a chemical buffer performs a similar function.

2 FRONTLOAD THE LESSON Divide the class into four groups of varying English speaking capabilities. Assign each group a different feature of the lesson to preview: Vocabulary, Figures and Tables, Sample Problem, and Lesson Check. Have groups present what they discovered to the class.

3 COMPREHENSIBLE INPUT Place two colors of plastic blocks (snapped together) in a large beaker to model that the sole source of ethanoate ions resulting from salt hydrolysis is ethanoic acid. Then add free blocks of a single color to show that both ethanoic acid and its acid salt are potential sources of ethanoate ions in an ethanoic acid/ethanoate buffer system.

Interpret Graphs



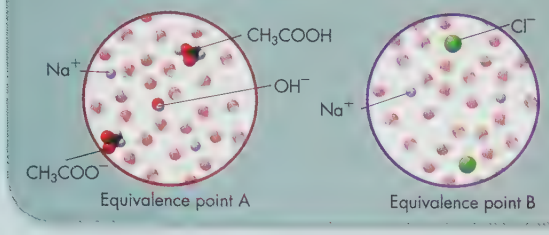


Figure 19.17 The graph compares the titration curves for a weak acid and a strong base with that for a strong acid and a strong base.

a. Read Graphs What is the pH of the equivalence point for each titration?

b. Interpret Diagrams What ions are present in each solution at the equivalence point?

c. Explain Why are the equivalence points of the two titrations different?

Hint: To answer part c, consider which reaction occurs in one solution that does not occur in the other.

The pH at the equivalence point for the weak acid-strong base titration is basic. For a strong acid-strong base titration, the pH at the equivalence point is neutral. This difference in pH exists because hydrolysis occurs with some salts in solution. In **salt hydrolysis,** the cations or anions of a dissociated salt remove hydrogen ions from, or donate hydrogen ions to, water. **Salts that produce acidic solutions have positive ions that release hydrogen ions to water. Salts that produce basic solutions have negative ions that attract hydrogen ions from water.**

Sodium ethanoate (CH_3COONa) is the salt of a weak acid and a strong base. In solution, the salt is completely ionized.

$$\underset{\text{Sodium ethanoate}}{CH_3COONa(aq)} \longrightarrow \underset{\text{Ethanoate ion}}{CH_3COO^-(aq)} + \underset{\text{Sodium ion}}{Na^+(aq)}$$

The ethanoate ion is a Brønsted-Lowry base, which means it is a hydrogen-ion acceptor. It reacts with water to form ethanoic acid and hydroxide ions. At equilibrium, the reactants are favored.

$$\underset{\substack{H^+ \text{ acceptor,}\\ \text{Brønsted-Lowry base}}}{CH_3COO^-(aq)} + \underset{\substack{H^+ \text{ donor,}\\ \text{Brønsted-Lowry acid}}}{H_2O(l)} \rightleftharpoons CH_3COOH(aq) + \underset{\substack{\text{(makes the}\\ \text{solution basic)}}}{OH^-(aq)}$$

This process is called hydrolysis because a hydrogen ion is split off a water molecule. The suffix *-lysis* comes from a Greek word meaning to "separate" or "loosen." In the solution, the hydroxide-ion concentration is greater than the hydrogen-ion concentration. Thus, the solution is basic.

UbD Check for Understanding

When is the solution of a salt acidic or basic?

Assess students' understanding of the Key Question by asking them to complete the following cloze prompt:

At the equivalence point of the titration of a _____ acid with a _____ base, the salt hydrolyzes to yield negative ions that attract hydrogen ions from water. *(weak; strong)*

ADJUST INSTRUCTION If students are having difficulty answering, have them examine the equation at the bottom of the page. **Ask** What type of ions are present in the solution at equilibrium? *(negative)* **Ask** What is the conjugate acid of ethanoate? *(ethanoic acid)* Point out that the products of the salt hydrolysis are the original reactants in the titration. Have students identify the strength of each reactant and then answer the cloze prompt again.

Foundations for Reading

BUILD VOCABULARY Have students look up the definitions of *capacity* and determine which definition is most appropriate for this lesson. Then have them define *buffer capacity* in their own words.

READING STRATEGY Have students construct a KWL chart about buffers, with the three column titles *What I Know About Buffers; What I Want to Know About Buffers; and What I Learned About Buffers.* Have students complete the appropriate columns before, during, and after reading this lesson.

Explain

Salt Hydrolysis

USE VISUALS Have students compare Figures 19.16 and 19.17. Note that the equivalence point is not always at pH 7. Explain that the salts may hydrolyze, resulting in a reversible reaction that produces a higher concentration of hydrogen or hydroxide ions. **Ask** How do neutralization reactions that produce a neutral solution at the equivalence point differ from those that produce acidic or basic solutions? *(In the strengths of the reactants; when a strong acid and a strong base react, the solution is neutral; when a strong base and a weak acid react, the solution is basic; when a strong acid and a weak base react, the solution is acidic.)*

Explore

Teacher Demo

PURPOSE Students predict the pH of different salt solutions and give reasons for their predictions.

MATERIALS 1*M* solutions of NH_4NO_3, KCl, $NaHCO_3$, Na_2SO_4; pH meter or universal pH paper

PROCEDURE Have students predict the pH of these solutions and explain their reasoning. After some discussion, check the pH of the solutions. Then ask students to explain about the data. *(NH_4NO_3 is acidic because the salt results from a strong acid and a weak base; KCl is neutral because the salt results from a strong acid and a strong base; $NaHCO_3$ is basic because the salt results from a strong base and a weak acid; Na_2SO_4 is neutral because the salt results from a strong acid and a strong base.)*

Answers

INTERPRET GRAPHS

a. (a) 8.7, (b) 7

b. (a) Na^+, OH^-, $CH3COO^-$ (b) Na^+, Cl^-

c. CH_3COO^- can react with water to produce OH^-.

MAKE A CONNECTION Point out that the salts that give non-neutral solutions in the pH demo are classified as Brønsted-Lowry acids and bases because the cations and anions of these salts accept or donate hydrogen ions from water (hydrolysis). Point out that the following relationships are a guide to predicting the type of solution expected from each combination of acid and base, and suggest that students commit them to memory:

Strong acid + Strong base → Neutral solution

Strong acid + Weak base → Acidic solution

Weak acid + Strong base → Basic solution

Explain

Buffers

USE VISUALS Direct students' to Figure 19.18. Explain that buffers are solutions in which the pH stays relatively constant when small amounts of either acid or base are added. Point out that in the buffered solution on the left, there is little change in pH.

Explore

TeacherDemo

PURPOSE To demonstrate that the neutralizing capacities of commercial buffers differ, students compare antacid tablets, buffered aspirin, and aspirin.

MATERIALS antacid tablets, flasks and burets, 0.5*M* HCl and NaOH, distilled water, methyl red, bromothymol blue

PROCEDURE Set up pairs of flasks containing 100 mL of distilled water to test each product. Dissolve equal masses of the tablets in each flask. Add a few drops of methyl red to one of the paired flasks and titrate with 0.5*M* NaOH. To the other flask, add a few drops of bromothymol blue and titrate with 0.5*M* HCl. Titrate until the end point is reached. Explain that the buffering capacity is directly related to the amount of acid or base required to reach the end point. Have students compare the buffering capacities of the tablets tested.

Ammonium chloride (NH_4Cl) is the salt of the strong acid hydrochloric acid (HCl) and the weak base ammonia (NH_3). It is completely ionized in solution.

$$NH_4Cl(aq) \longrightarrow NH_4^+(aq) + Cl^-(aq)$$

The ammonium ion (NH_4^+) is a strong enough acid to donate a hydrogen ion to a water molecule. The products are ammonia molecules and hydronium ions. The reactants are favored at equilibrium, as shown by the relative sizes of the forward and reverse arrows.

$$\underset{\substack{H^+ \text{ donor,}\\ \text{Brønsted-Lowry acid}}}{NH_4^+(aq)} + \underset{\substack{H^+ \text{ acceptor,}\\ \text{Brønsted-Lowry base}}}{H_2O(l)} \rightleftharpoons NH_3(aq) + \underset{\substack{\text{(makes the}\\ \text{solution acidic)}}}{H_3O^+(aq)}$$

This process is another example of hydrolysis. At equilibrium the $[H_3O^+]$ is greater than the $[OH^-]$. Thus, a solution of ammonium chloride is acidic. To determine if a salt will form an acidic or basic solution, remember the following rules:

Strong acid + Strong base ⟶ Neutral solution

Strong acid + Weak base ⟶ **Acidic** solution

Weak acid + **Strong base** ⟶ **Basic** solution

Buffers

What are the components of a buffer?

Suppose you add 10 mL of 0.10*M* sodium hydroxide to 1 L of pure water. The pH will increase about 4 pH units—from 7.0 to about 11.0. This change is a relatively large increase in pH. Now consider a solution containing 0.20*M* each of ethanoic acid and sodium ethanoate. This solution has a pH of 4.76. If you add 10 mL of 0.10*M* sodium hydroxide to 1 L of this solution, the pH increases 0.01 pH units—from 4.76 to 4.77. This is a relatively small change in pH. If 10 mL of acid had been added instead of the base, the amount of change in pH would also have been small.

The solution of ethanoic acid and sodium ethanoate is an example of a buffer. A **buffer** is a solution in which the pH remains fairly constant when small amounts of acid or base are added. **A buffer is a solution of a weak acid and one of its salts or a solution of a weak base and one of its salts.** Figure 19.18 compares what happens when 1.0 mL of 0.01*M* HCl solution is added to an unbuffered solution and to a solution with a buffer.

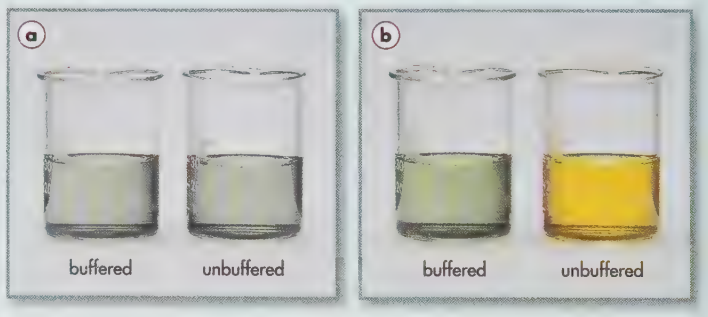

Figure 19.18 Effect of a Buffer In a buffer solution, the pH does not shift dramatically. **a.** The indicator shows that both solutions are basic (pH of about 8). **b.** HCl is added to each solution. The indicator shows no visible pH change in the buffered solution. The color change in the unbuffered solution indicates a change in pH from 8 to about 3. **Predict** ***How would the original solutions respond if NaOH were added?***

Differentiated Instruction

L1 STRUGGLING STUDENTS For students who may benefit from a closer examination of the teacher demos, allow time before class for them to come in and observe the lab on a closer level. Allow students to participate in the lab, and guide student understanding by using the thinking aloud technique.

ELL ENGLISH LANGUAGE LEARNERS Students with limited English proficiency may be confused by the terms *equivalents* and *equivalence*, which sound alike and have similar spellings. Have them write out both words and underline or circle the differences in the endings. Help them write out meaningful definitions for both words.

L3 ADVANCED STUDENTS Have students design and implement a lab to determine the difference between a buffered aspirin and a regular aspirin.

How Buffers Work A buffer solution is better able to resist drastic changes in pH than is pure water. The reason is fairly simple. A buffer solution contains one component that can react with hydrogen ions (a hydrogen-ion acceptor) and another component that can react with hydroxide ions (a hydrogen-ion donor). These components act as reservoirs of neutralizing power that can be tapped when either hydrogen ions or hydroxide ions are added to the solution.

The ethanoic acid–ethanoate ion buffer can be used to show how a buffer works. When an acid is added to the buffer, the ethanoate ions (CH_3COO^-) act as a hydrogen-ion "sponge." As the ethanoate ions react with the hydrogen ions, they form ethanoic acid. This weak acid does not ionize extensively in water, so the change in pH is very slight.

$$\underset{\text{Ethanoate ion}}{CH_3COO^-(aq)} + \underset{\text{Hydrogen ion}}{H^+(aq)} \rightleftharpoons \underset{\text{Ethanoic acid}}{CH_3COOH(aq)}$$

When hydroxide ions are added to the buffer, the ethanoic acid and the hydroxide ions react to produce water and the ethanoate ion.

$$\underset{\text{Ethanoic acid}}{CH_3COOH(aq)} + \underset{\text{Hydroxide ion}}{OH^-(aq)} \rightleftharpoons \underset{\text{Ethanoate ion}}{CH_3COO^-(aq)} + \underset{\text{Water}}{H_2O(l)}$$

The ethanoate ion is not a strong enough base to accept hydrogen ions from water to a great extent. Therefore, the reverse reaction is minimal and the change in pH is very slight.

The Capacity of a Buffer Buffer solutions have their limits. As acid is added to an ethanoate buffer, eventually no more ethanoate ions will be present to accept the hydrogen ions. At that point, the buffer can no longer control the pH. The ethanoate buffer also becomes ineffective when too much base is added. In that case, no more ethanoic acid molecules are present to donate hydrogen ions. Adding too much acid or base will exceed the buffer capacity of a solution. The **buffer capacity** is the amount of acid or base that can be added to a buffer solution before a significant change in pH occurs.

Table 19.9 lists some common buffer systems. Two of these buffer systems help maintain optimal human blood pH. One is the carbonic acid–hydrogen carbonate buffer system. The other is the dihydrogen phosphate–hydrogen phosphate buffer system.

CHEMISTRY & YOU

Q: *The equilibrium between carbonic acid (H_2CO_3) and hydrogen carbonate ions (HCO_3^-) helps keep the pH of blood within a narrow range (7.35–7.45). If the pH rises, molecules of carbonic acid donate hydrogen ions. What can happen if the pH drops, that is, if the $[H^+]$ increases?*

Table 19.9

Important Buffer Systems

Buffer name	Formulas	Buffer pH*
Ethanoic acid–ethanoate ion	CH_3COOH/CH_3COO^-	4.76
Dihydrogen phosphate ion–hydrogen phosphate ion	$H_2PO_4^-/HPO_4^{2-}$	7.20
Carbonic acid–hydrogen carbonate ion (solution saturated with CO_2)	H_2CO_3/HCO_3^-	6.46
Ammonium ion–ammonia	NH_4^+/NH_3	9.25

*Components have concentrations of 0.1*M*.

Professional Development Note

Blood Buffers

Your body functions properly only when the pH of your blood lies between 7.35 and 7.45. A blood pH outside these narrow limits can be life threatening. To keep your blood at the proper pH, your blood contains buffers. The most important blood buffer consists of carbonic acid and hydrogen carbonate ions. Hydrogen ions produced by chemical reactions in your body are the main threat to your blood's pH. This buffer maintains the desired blood pH by removing excess hydrogen ions.

$$HCO_3^-(aq) + H^+(aq) \rightleftharpoons H_2CO_3(aq)$$

As long as there are hydrogen carbonate ions available, the excess hydrogen ions are removed, and the pH of the blood changes very little.

Explain

APPLY CONCEPTS Explain that buffers present a practical application of concepts in this chapter. Point out that the limited dissociation of weak acids and bases gives these substances the ability to act as buffers. This ability is greatly expanded if the salt of the acid or base is added to the solution. Explain that buffer action utilizes the equilibrium established when a weak acid or base is combined with its salt. Convey that when a base is added to a buffered solution, the acidic form removes hydroxide ions from the solution. When an acid is added to a buffered solution, the basic form removes hydrogen ions from the solution.

CHEMISTRY & YOU If the pH drops, carbonate ions react with the excess hydrogen ions and form carbonic acid.

Extend

Connect to BIOCHEMISTRY

Explain that the choice of buffering system is determined by its effective pH range, which can be determined by calculating the pK_a of the system's acid. **Ask** How do you think that a pK_a is calculated? *(Students should notice that pK_a looks similar to pH and should suggest that it can be calculated by taking the negative logarithm of the acid's dissociation constant.)* Explain that the effective pH range is approximately equal to the pK_a +/– 1. **Ask** Why do you think many biochemical experiments use buffers with pK_a values in the 7 to 8 range? *(Many biochemical experiments involve chemicals found in the body, which has a pH of 7.4, which is referred to as physiological pH. Enzymes in particular are sensitive to pH. Buffers with pK_a values in the 7 to 8 range are used because they help maintain the pH of the experimental system at physiological pH.)*

Answers

FIGURE 19.18 There would be no visible change in the buffered solution. There would be a color change in the unbuffered solution indicating an increase in pH.

Evaluate

Informal Assessment

Have students explain in their own words what determines whether a solution containing a hydrolyzing salt is acidic or basic. *(Salts formed from a strong acid and strong base are neutral. Those formed from a strong base and weak acid are basic; those formed from a strong acid and weak base are acidic.)* **Ask** How can ethanoate ions effectively remove hydrogen ions from solution? *(The ethanoate ions are a Brønsted–Lowry base that accept the hydrogen ions to form ethanoic acid.)* Then have students complete the 19.5 Lesson Check.

Reteach

Point out that a hydrolysis reaction always uses one part of the water molecule and leaves behind the other. Use equations to show students how the salt of a weak acid always reacts with water to produce hydroxide ions and the salt of a weak base always reacts to produce hydrogen ions. Remind students that chemical buffers are equilibrium systems that tend to resist change due to external influences.

Sample Practice Problem

Contact lens solution often contains boric acid as a buffer. Write the equation for the reaction that shows what happens when an acid is added to a buffer system containing boric acid (H_3BO_3) and dihydrogen borate ions ($H_2BO_3^-$). *($H_2BO_3^- + H^+ \rightarrow H_3BO_3$)*

Answers

SAMPLE PROBLEM 19.9

44. **a.** $HPO_4^{2-} + H^+ \rightarrow H_2PO_4^-$
b. $H_2PO_4^- + OH^- + HPO_4^{2-} \rightarrow H_2O$

45. $HCOO^- + H^+ \rightarrow HCOOH$

Sample Problem 19.9

Describing Buffer Systems

Write balanced chemical equations to show how the carbonic acid–hydrogen carbonate buffer can "mop up" added hydroxide ions and hydrogen ions.

1 Analyze **Identify the relevant concepts.** A buffer contains two components: a hydrogen-ion acceptor (which can react with H^+) and a hydrogen-ion donor (which can react with OH^-).

2 Solve **Apply the concepts to this problem.**

Identify the hydrogen ion acceptor and the hydrogen-ion donor.

H_2CO_3, a weak acid, can release hydrogen ions. HCO_3^- is the conjugate base, which can accept hydrogen ions.

Write the equation for the reaction that occurs when a base is added to the buffer.

When a base is added, the hydroxide ions react with H_2CO_3.

$$H_2CO_3(aq) + (OH^-)(aq) \rightleftharpoons HCO_3^-(aq) + H_2O(l)$$

Write the equation for the reaction that occurs when an acid is added to the buffer.

When an acid is added, the hydrogen ions react with HCO_3^-.

$$HCO_3^-(aq) + (H^+)(aq) \rightleftharpoons H_2CO_3(aq)$$

44. Write equations to show what happens in the following situations:
a. Acid is added to a solution that contains HPO_4^{2-} ions.
b. Base is added to a solution that contains $H_2PO_4^-$ ions.

45. A buffer consists of methanoic acid (HCOOH) and methanoate ion ($HCOO^-$). Write an equation to show what happens when an acid is added to this buffer.

19.5 LessonCheck

46. **Review** What type of salt produces an acidic solution? What type of salt produces a basic solution?

47. **Describe** What types of substances can be combined to make a buffer solution?

48. **Classify** Which of these salts would hydrolyze to produce an acidic aqueous solution, and why?
a. $KC_2H_3O_2$
b. LiCl
c. $NaHCO_3$
d. $(NH_4)_2SO_4$

49. **Identify** Which of the following pairs can form a buffer solution? Explain.
a. NH_3 and HCO_3^-
b. C_6H_5COOH and $C_6H_5COO^-$

50. **Describe** Write a balanced chemical equation to show what happens when an acid is added to an ammonium ion–ammonia buffer. Write an equation to show what happens when a base is added.

51. **Relate Cause and Effect** Use Le Châtelier's principle to explain how a buffer system maintains the pH of a solution.

Lesson Check Answers

46. acidic solution: salt of a strong acid and weak base; basic solution: salt of a weak acid and a strong base

47. a weak acid and one of its salts or a weak base and one of its salts

48. d

49. Pair (b) because it consists of a weak acid and one of its salts.

50. $NH_3 + H \rightarrow NH_4^+$
$NH_4^+ + OH^- \rightarrow NH_3 + H_2O$

51 According to Le Châtelier, when a system in equilibrium is disturbed, the response is an attempt to restore the equilibrium. When the stress is the addition of an acid or a base, a buffer system helps to restore the equilibrium.

Ocean Buffers

As atmospheric carbon dioxide (CO_2) levels rise due to increased burning of fossil fuels, global warming is not the only potential environmental problem that Earth faces. Additionally, ocean water becomes more acidic, which can disrupt the ocean ecosystem.

The oceans naturally absorb CO_2 from the atmosphere. Some of the absorbed CO_2 is converted to carbonic acid (H_2CO_3), which can lower the pH of ocean water. Fortunately, the oceans have an excellent natural buffer system that helps maintain the optimal pH for supporting ocean life—about 8.2. The ocean's buffer system is largely based on the hydrogen carbonate–carbonate ion buffer system. However, the buffer capacity of the buffers in ocean water is limited, and current human activities are pushing these limits.

Try the following activity at home to gain a better understanding of the effects of CO_2 and sea salt on the pH of ocean water.

On Your Own

1. For this activity, you will need the following materials: **4 drinking glasses, masking tape, a permanent marker, distilled water, carbonated water, sea salt, a measuring cup, ¼ teaspoon measuring spoon,** and **4 pH test strips.** (You can ask your teacher for pH test strips if you do not have them at home.) Use the masking tape and marker to label the glasses 1, 2, 3, and 4.

2. Add ½ cup of distilled water to glasses 1 and 2. Add ½ cup of carbonated water to glasses 3 and 4.

3. Add ¾ teaspoon of sea salt to containers 2 and 4. Stir until the salt is dissolved. (This ratio of sea salt to water is similar to that found in the ocean.)

4. Measure the pH of each solution and record it in a table similar to the one shown to the right.

What Did You Find?				
Glass	1	2	3	4
Contents				
pH				

Think About It

1. Compare Determine whether each solution is acidic, basic, or neutral. How do the four solutions differ?

2. Explain How does a solution containing hydrogen carbonate ions (HCO_3^-) and carbonate ions (CO_3^{2-}) act as a buffer? Use chemical equations to support your explanation.

3. Draw Conclusions What does this experiment demonstrate about the effects of dissolved CO_2 (in the carbonated water) and sea salt on the pH of ocean water?

Differentiated Instruction

L1 STRUGGLING STUDENTS Arrange for students to work on the activity in pairs. Discuss each step with them beforehand. Ask questions to be sure they understand what to do.

LPR LESS PROFICIENT READERS Help students make a checklist that includes gathering the materials for the activity and following each step. They should rewrite the instructions for each step in simple words.

L3 ADVANCED STUDENTS Have students gather the data from the entire class and prepare a class chart or graph. Students should display their chart or graph in the classroom and explain it.

CHEMISTRY & YOU Have students look at the photograph. Discuss what might happen to the organisms if the acidity of the water increased significantly. Explain that organisms are adapted to live in certain ecosystems. If the ecosystem changes, organisms that cannot adapt to the change must move to a different area or they will die. In the ocean, moving to an ecosystem that is not affected by the change in pH may not be possible.

Explain

Draw a Diagram To help students understand the purpose and importance of ocean buffers, have a student volunteer make a flow chart on the board, with the help of the class. Starting with factors that increase carbon dioxide levels in the atmosphere, go to the absorption of carbon dioxide by ocean water, and then to the action of buffers in the ocean. Encourage students to add information they already know to the facts provided in the feature. After the flowchart is complete, discuss causes and results of each step. For example, burning fossils fuel can increase the carbon dioxide levels in the atmosphere. Water can absorb carbon dioxide through the following reaction.

$$CO_2(g) + H_2O + Ca^{2+}(aq) \rightleftharpoons CaCO_3(s) + 2H^+(aq)$$

Extend

Connect to BIOLOGY

Explain that coral reefs are made from the skeletons of corals, and these skeletons are made of calcium carbonate. Coral reefs are home to a vast number of organisms. **Ask** Why could even a slight increase in ocean acidity be devastating to a coral reef ecosystem? *(The acidic water could dissolve the calcium carbonate, and destroy the reef.)*

Answers

THINK ABOUT IT

1. Cup 1 is neutral, cup 2 is basic, cups 3 and 4 are acidic, but cup 4 is less acidic.
2. The sea salt added hydroxide ions to the water. The hydrogen carbonate ions reacted with the hydroxide ions, producing carbonate ions and water.
3. Sea salt increase the pH of water. The dissolved carbon dioxide establishes a buffer system that helps maintain the pH at an optimum level.

WALK-THRU Each of the Math Tune-Up problems on this page has as animated step-by-step tutorial that explains the problem-solving strategy in detail.

PROBLEM SETS Have students practice more problems by using the Chapter 19 Online Problem Set.

MATH SKILLS Have struggling students practice manipulating algebraic equations by using the MathXL learning module.

VIRTUAL LABS Have students complete a virtual lan as an in-class or take-home assignment to help reinforce the concept of acid-base reactions.

Study Tip

GET INTO THE HABIT OF ACTIVELY STUDYING EACH DAY Offer students the following advice: Take time each night to review the day's work. Make notes of difficult concepts to ask your teacher about or to discuss with a study friend.

19 Study Guide

BIG IDEA REACTIONS

Chemists define acids and bases according to the ions they yield in aqueous solution. Chemists also define acids and bases based on whether they accept or donate hydrogen ions, and whether they are electron-pair donors or acceptors. The pH of a solution reflects the hydrogen-ion concentration. Chemists use acid-base reactions to determine the concentration of an acid or a base in solution.

Key Equations

$$K_w = [H^+] \times [OH^-] = 1.0 \times 10^{-14}$$

$$pH = -\log[H^+]$$

19.1 Acid-Base Theories

- According to Arrhenius, acids are hydrogen-containing compounds that ionize to yield hydrogen ions in aqueous solution. Bases are compounds that ionize to yield hydroxide ions in aqueous solution.
- According to the Brønsted-Lowry theory, an acid is a hydrogen-ion donor and a base is a hydrogen-ion acceptor.
- According to Lewis, an acid accepts a pair of electrons and a base donates a pair of electrons.

- hydronium ion (H_3O^+) (647)
- conjugate acid (650)
- conjugate base (650)
- conjugate acid-base pair (650)
- amphoteric (651)
- Lewis acid (651)
- Lewis base (651)

19.2 Hydrogen Ions and Acidity

- For aqueous solutions, the product of the hydrogen-ion concentration and the hydroxide-ion concentration equals 1×10^{-14}.
- A solution with a pH less than 7.0 is acidic. A solution with a pH of 7 is neutral. A solution with a pH greater than 7.0 is basic.
- Either acid-base indicators or pH meters can be used to measure pH.

- self-ionization (653)
- neutral solution (653)
- ion-product constant for water (K_w) (654)
- acidic solution (654)
- basic solution (654)
- pH (656)

19.3 Strengths of Acids and Bases

- Acids and bases are classified as strong or weak based on the degree to which they ionize in water.

- strong acid (664)
- weak acid (664)
- acid dissociation constant (K_a) (665)
- strong base (668)
- weak base (668)
- base dissociation constant (K_b) (668)

Key Equation

$$K_a = \frac{[H^+][A^-]}{[HA]}$$

19.4 Neutralization Reactions

- In general, acids and bases react to produce a salt and water.
- Neutralization occurs when the number of moles of hydrogen ions is equal to the number of moles of hydroxide ions.

- neutralization reaction (672)
- titration (673)
- standard solution (674)
- equivalence point (674)
- end point (674)

19.5 Salts in Solution

- Salts that produce acidic solutions have positive ions that release hydrogen ions to water. Salts that produce basic solutions have negative ions that attract hydrogen ions from water.
- A buffer is a solution of a weak acid and one of its salts or a weak base and one of its salts.

- salt hydrolysis (677)
- buffer (678)
- buffer capacity (679)

UbD Performance Tasks

KITCHEN CHEMISTRY Have students randomly select six solutions from their kitchens to investigate. Tell them to create a table noting the common name, chemical name, and purpose for each substance. Review the lists for safety before students determine whether the solutions are acidic, basic, or neutral. Tell students to create a plot that visually shows the items from least basic to most basic and to present their findings to the class.

PHUN IN CHEMISTRY Tell students to create a computer slide show that compares the two methods of measuring pH and explains how, when, and why you use each method. Have them determine five different household items that can each be used as an acid/base indicator pH paper or a pH meter were not available. Tell them to explain how they know these items can be used as indicators and to describe the method for preparing and using each of them.

Math Tune-Up: Acid-Base Problems

Problem	❶ Analyze	❷ Calculate	❸ Evaluate
The pH of an unknown solution is 3.70. What is the hydrogen-ion concentration?	Known: pH = 3.70 Unknown: $[H^+] = ?M$ Use the following equation: $pH = -\log[H^+]$	Rearrange the expression for pH and substitute the known pH value to solve for the unknown: $-\log[H^+] = pH$ $-\log[H^+] = 3.70$ $\log[H^+] = -3.70$ The antilog of −3.70 is 2.0×10^{-4}. Thus, $[H^+] = 2.0 \times 10^{-4}M$. Note: To determine the antilog on most calculators, press the 2nd or INV key then the log key.	The pH is between 3 and 4. So, the hydrogen ion concentration must be between $1 \times 10^{-3}M$ and $1 \times 10^{-4}M$.
In a 0.500M solution of a weak acid (HA), the $[H^+]$ is 4.02×10^{-3} at equilibrium. Find the K_a for this acid. The acid dissociates as follows: $HA \rightleftharpoons H^+ + A^-$	Knowns: $[HA] = 0.500M$ $[H^+] = 4.02 \times 10^{-3}$ Unknown: $K_a = ?$ Use the general expression for K_a: $K_a = \frac{[H^+] \times [A^-]}{[HA]}$ Hint: Review Sample Problem 19.6 for help on finding equilibrium concentrations.	At equilibrium, $[H^+]$ is equal to $[A^-]$: $[H^+] = [A^-] = 4.02 \times 10^{-3}$ Calculate [HA] at equilibrium: $0.500M - 0.00402M = 0.496M$ Substitute the equilibrium concentrations into the equation for K_a and solve: $K_a = \frac{(4.02 \times 10^{-3}) \times (4.02 \times 10^{-3})}{0.496}$ $K_a = 3.26 \times 10^{-5}$	The value of K_a is consistent with that of a weak acid.
How many moles of KOH are needed to neutralize 0.25 mol of H_2SO_4? The equation for the reaction is $2KOH(aq) + H_2SO_4(aq) \longrightarrow K_2SO_4(aq) + 2H_2O(l)$	Known: mol H_2SO_4 = 0.25 mol Unknown: mol KOH = ? mol	Use the mole ratio of base to acid (2 mol KOH to 1 mol H_2SO_4) to determine the number of moles of base: $0.25 \text{ mol } H_2SO_4 \times \frac{2 \text{ mol KOH}}{1 \text{ mol } H_2SO_4}$ = 0.50 mol KOH	The mole ratio of KOH to H_2SO_4 is 2:1. So, the number of moles of KOH should be twice the number of moles of H_2SO_4.

Focus on ELL

5 ASSESS UNDERSTANDING Assess students' understanding by using a portfolio. Include various learning assignments, based on each student's language proficiency.

BEGINNING:

LOW Include models or pictures of models created by the student.

HIGH Include copies of the graphic organizers used to take notes or any cause-and- effect charts.

INTERMEDIATE:

LOW Include any prereading predictions about lesson topics, as well as the results of those predictions.

HIGH Include any lab write-ups that were assigned during the chapter.

ADVANCED: LOW/HIGH Include an essay that requires the student to compare and contrast different acid-base theories.

19.1 Acid-Base Theories

*52. How did Arrhenius describe acids and bases?

53. Classify each compound as an Arrhenius acid or an Arrhenius base.
a. $Ca(OH)_2$ **c.** HNO_3 **e.** HBr
b. C_2H_5COOH **d.** KOH **f.** H_2SO_4

54. Write an equation for the dissociation of each compound in water.
a. KOH **b.** $Mg(OH)_2$

*55. Write balanced equations for the reaction of each metal with water.
a. lithium **b.** barium

56. Identify each reactant in the following equations as a hydrogen-ion donor (acid) or a hydrogen-ion acceptor (base). All the reactions take place in aqueous solution.
a. $HNO_3 + H_2O \longrightarrow H_3O^+ + NO_3^-$
b. $CH_3COOH + H_2O \rightleftharpoons H_3O^+ + CH_3COO^-$
c. $NH_3 + H_2O \rightleftharpoons NH_4^+ + OH^-$
d. $H_2O + CH_3COO^- \rightleftharpoons CH_3COOH + OH^-$

57. Label the conjugate acid-base pairs for each equation in Question 56.

58. What is a Lewis acid? What is a Lewis base?

19.2 Hydrogen Ions and Acidity

59. Write an equation showing the self-ionization of water.

60. What are the concentrations of H^+ and OH^- in pure water at 25°C?

61. How is the pH of a solution calculated?

62. Why is the pH of pure water at 25°C equal to 7.0?

*63. Calculate the pH for the following solutions and indicate whether each solution is acidic or basic.
a. $[OH^-] = 1 \times 10^{-2}M$ **b.** $[H^+] = 1 \times 10^{-2}M$

64. What are the hydroxide-ion concentrations for solutions with the following pH values?
a. 4.00 **b.** 8.00 **c.** 12.00

65. Calculate the pH or $[H^+]$ for each solution.
a. $[H^+] = 2.4 \times 10^{-6}M$ **b.** pH = 13.20

19.3 Strengths of Acids and Bases

*66. Identify each compound as a strong or weak acid or base.
a. NaOH **b.** NH_3 **c.** H_2SO_4 **d.** HCl

67. Would a strong acid have a large or a small K_a? Explain your answer.

68. Why are $Mg(OH)_2$ and $Ca(OH)_2$ classified as strong bases even though their saturated solutions are only mildly basic?

69. Write the expression for K_a for each acid. Assume only one hydrogen is ionized.
a. HF **b.** H_2CO_3

19.4 Neutralization Reactions

70. Write a general word equation for a neutralization reaction.

71. Identify the products and write balanced equations for each neutralization reaction.
a. $HNO_3(aq) + KOH(aq) \longrightarrow$
b. $HCl(aq) + Ca(OH)_2(aq) \longrightarrow$
c. $H_2SO_4(aq) + NaOH(aq) \longrightarrow$

72. How is it possible to recognize the end point of a titration?

*73. What is the molarity of sodium hydroxide if 20.0 mL of the solution is neutralized by each of the following 1.00*M* solutions?
a. 28.0 mL of HCl
b. 17.4 mL of H_3PO_4

19.5 Salts in Solution

74. What kinds of salts hydrolyze water?

*75. Write an equation showing why an aqueous solution of sodium hydrogen carbonate is basic.

76. Explain why solutions of salts that hydrolyze water do not have a pH of 7.

77. Predict whether an aqueous solution of each salt will be acidic, basic, or neutral.
a. $NaHCO_3$ **d.** Na_2CO_3
b. NH_4NO_3 **e.** Na_2SO_4
c. KCl **f.** NH_4Cl

78. Explain why a buffered solution cannot absorb an unlimited amount of acid or base.

LESSON 19.5

74. salts with a cation from a week base and an anion from a strong acid, or with a cation from a strong base and an anion from a weak acid.

75. $HCO_3^-(aq) + H_2O(l) \rightarrow H_2CO_3(aq) + OH^-(aq)$

76. Weak-acid anions accept protons from water, increasing the ph of the solution. Weak-base cations donate protons to water, decreasing the pH.

77. **a.** basic **b.** acidic **c.** neutral
d. basic **e.** neutral **f.** acidic.

78. Eventually the buffer capacity of the buffer is exceeded and the pH will change significantly with the addition of a strong acid or base.

Understand Concepts

79. Explain how the Lewis theory is a more general classification system than either the Arrhenius descriptions or the Brønsted-Lowry theory.

80. Is it possible to have a concentrated weak acid? Explain.

***81.** Write equations showing that the hydrogen phosphate ion (HPO_4^{2-}) is amphoteric.

82. The pH of a 0.5000*M* HNO_2 solution is 1.83. What is the K_a of this acid?

83. How do the $[H^+]$ and the $[OH^-]$ compare in each type of solution?

a. neutral solution
b. basic solution
c. acidic solution

84. Write the formula and name of the conjugate base of each Brønsted-Lowry acid.

a. HCO_3^- **b.** NH_4^+ **c.** HI **d.** H_2SO_3

***85.** Write the formula and name of the conjugate acid of each Brønsted-Lowry base.

a. ClO_2^- **b.** H_2O **c.** $H_2PO_4^-$ **d.** NH_3

86. Calculate the $[OH^-]$ or pH of each solution.

a. pH = 4.60 **c.** $[OH^-] = 1.8 \times 10^{-2}M$
b. pH = 9.30 **d.** $[OH^-] = 7.3 \times 10^{-9}M$

87. Write the three equations for the stepwise ionization of phosphoric acid.

88. Use the Brønsted-Lowry and Lewis definitions of acids and bases to identify each reactant as an acid or a base.

a. $KOH(aq) + HBr(aq) \longrightarrow KBr(aq) + H_2O(l)$
b. $HCl(aq) + H_2O(l) \longrightarrow Cl^-(aq) + H_3O^+(aq)$

89. Write the formula for the conjugate base of each of the following acids:

a. H_2SO_4 **b.** CH_3COOH **c.** H_2O

90. Use the phosphate buffer ($H_2PO_4^-/HPO_4^{2-}$) to illustrate how a buffer system works. Use equations to show how the pH of a solution can be kept almost constant when small amounts of acid or base are added.

***91.** Write an equation for the reaction of each antacid with hydrochloric acid.

a. magnesium hydroxide
b. calcium carbonate
c. aluminum hydroxide

92. How would the addition of each substance affect the equilibrium between hypochlorous acid and the hypochlorite ion?

$$HOCl(aq) + OH^-(aq) \rightleftharpoons OCl^-(aq) + H_2O(l)$$

a. HCl **b.** NaOH

93. The following data were collected from a titration of 50.00 mL of ethanoic acid (CH_3COOH) of unknown concentration with 0.100*M* NaOH. Plot these data to obtain a titration curve. Place pH on the *y*-axis.

Volume of NaOH (mL)	pH	Volume of NaOH (mL)	pH
0	3.18	50.00	8.73
10.00	4.15	50.01	8.89
25.00	4.76	51.00	11.00
40.00	5.36	60.00	11.96
49.00	6.45	75.00	12.30
49.99	8.55	100.00	12.52

a. What is the pH at the end point of this titration?
b. Use Figure 19.8 to identify one or more acid-base indicators that could be used to determine the end point in this titration.

94. Write an equation to show that an aqueous solution of sodium ethanoate will be basic.

***95.** Arrange the following solutions in order of decreasing acidity:

a. 0.1*M* NaOH **c.** 0.1*M* NH_4Cl
b. 0.1*M* HCl **d.** 0.1*M* CH_3COONa

96. Vapors of the strong acid HCl(*aq*) and the weak base $NH_3(aq)$ combine to form a white salt.

a. What is the name and formula of the salt?
b. What kind of solution will this salt form when it dissolves in water?

Answers

UNDERSTAND CONCEPTS

79. The Lewis theory explains the behavior of compounds that act like bases without accepting hydrogen ions or that act like acids without donating hydrogen.

80. Yes, acids like acetic acid dissolve well but ionize poorly.

81. $HPO_4^{2-} \rightarrow H^+ + PO_4^{3-}$ (acting as an acid);
$HPO_4^{2-} + H^+ \rightarrow H_2PO_4^-$ (acting as a base)

82. 4.6×10^{-4}

83. **a.** The concentrations are equal.
b. $[OH^-]$ is greater than $[H^+]$
c. $[H^+]$ is greater than $[OH^-]$

84. **a.** CO_3^{2-}, carbonate ion
b. NH_3, ammonia
c. I^-, iodide ion
d. HSO_3^-, hydrogen sulfite ion.

85. **a.** $HClO_2$, chlorous acid
b. H_3O^+, hydronium ion
c. H_3PO_4, phosphoric acid
d. NH_4^+, ammonium ion.

86. **a.** $[OH^-] = 4.0 \times 10^{-10}M$
b. $[OH^-] = 2.0 \times 10^{-5}M$
c. pH = 12.26
d. pH = 5.86

87. $H_3PO_4 \rightleftharpoons H^+ + H_2PO_4^-$;
$H_2PO_4^- \rightleftharpoons H^+ + H_2PO_4^{2-}$;
$HPO_4^{2-} \rightleftharpoons H^+ + PO_4^{3-}$

88. **a.** KOH is the base; HBr is the acid.
b. HCl is the acid; H_2O is the base.

89. **a.** HSO_4^-
b. CH_3COO^-
c. OH^-

90. $H_2PO_4 + OH \rightleftharpoons H_2O + HPO_4^{2-}$

91. **a.** $2HCl + Mg(OH)_2 \rightarrow MgCl_2 + 2H_2O$
b. $2HCl + CaCO_3 \rightarrow H_2O + CO_2 + CaCl_2$
c. $Al(OH)_3 + 3HCl \rightarrow AlCl_3 + 3H_2O$

92. **a.** shift to the left
b. shift to the right

93. **a.** 8.73
b. phenolphthalein or phenol red

94. $NaC_2H_3O_2 + H_2O \rightarrow Na^+ + HC_2H_3O_2 + OH^-$

95. b, c, d, a

96. **a.** NH_4Cl
b. acidic

ASSESSMENT

Evaluate

Answers

THINK CRITICALLY

97. a. Students are likely to consider the Arrhenius explanation the easiest to understand, and the Lewis theory the best because it is the most general.

b. All three explanations provide definitions and describe accepted behavior of a certain group of compounds. The Brønsted-Lowry theory includes a greater number of compounds than the Arrhenius explanation because it is more general, and the Lewis theory includes the greatest number of compounds because it is the most general.

98. CO_2 concentration is higher in pure water. Less CO_2 becomes carbonate because pure water does not have OH^- ions needed to reduce H^+ concentration.

99. a. False; an indicator determines a range of pH values.

b. False; an Arrhenius base dissociates to give hydroxide ions in aqueous solution. Ammonia does not do this.

c. False; strength is a measure of dissociation or ionization, not concentration.

100. $HOCN + OH^- \rightleftharpoons H_2O + OCN^-$
$OCN^- + H^+ \rightleftharpoons HOCN$

101. The *y*-axis might correspond to $[H^+]$ because HCl is a strong acid.

102. 3.88×10^{-4}

103. a. $NaOH + HCl \rightarrow NaCl + H_2O$

b. 0.72*M* NaOH

104. 50.0 mL; The pH = 7 when $[H^+] = [OH^-]$. Because HCl is a strong acid that supplies one hydrogen ion per formula unit and NaOH is a strong base that supplies one hydroxide ion per formula unit, $[H^+] = [OH^-]$ when equal volumes of solutions of the same molarity are combined.

105. a. neutral
b. neutral
c. basic
d. acidic
e. neutral

106. $pOH = -\log [OH^-]$

107. pOH = 7.3

108. Because $\log (a \times D) = \log a + \log b$, and $K_w = [H^+] \times [OH^-] = 1.0 \times 10^{-14}$, taking the log of each concentration term gives: $\log [H^+] + \log [OH^-] = -14$; $-\log [H^+] - \log [OH^-] = 14$; $pH + pOH = 14$.

Think Critically

97. Compare Arrhenius, Brønsted-Lowry, and Lewis all offered explanations for the behavior of acids and bases.

a. Which explanation is easiest for you to understand?

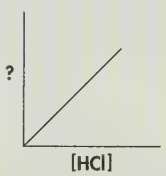
b. How is it possible for all three explanations to be accepted by chemists?

98. Predict The solubility of carbon dioxide in water depends on four different reversible reactions.

$$CO_2(g) \rightleftharpoons CO_2(aq)$$
$$CO_2(aq) + H_2O(l) \rightleftharpoons H_2CO_3(aq)$$
$$H_2CO_3(aq) \rightleftharpoons H^+(aq) + HCO_3^-(aq)$$
$$HCO_3^-(aq) \rightleftharpoons H^+(aq) + CO_3^{2-}(aq)$$

If seawater is slightly alkaline, would you expect the concentration of dissolved CO_2 to be higher or lower than in pure water? Explain your answer.

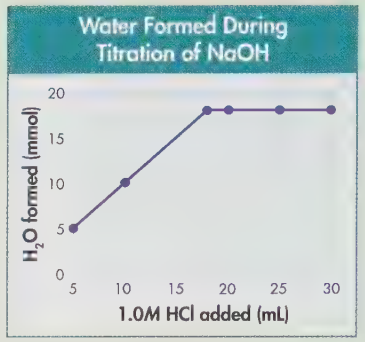
99. Evaluate Critique the accuracy of each of these statements.



a. Indicators such as methyl red provide accurate and precise measurements of pH.

b. According to the Arrhenius definition of acids and bases, ammonia qualifies as a base.

c. The strength of an acid or base changes as its concentration changes.



***100. Relate Cause and Effect** Use the cyanate buffer $HOCN/OCN^-$ to explain how a buffer system works. Use equations to show how the pH of a solution can be kept almost constant when small amounts of acid or base are added.

***101. Identify** Which quantity might correspond to the *y*-axis on this graph: $[H^+]$, pH, or $[OH^-]$? Explain your answer.

102. Calculate The sugar substitute saccharin ($HNC_7H_4SO_3$) has one acidic hydrogen. A 1.000*M* aqueous solution of saccharin has a pH of 1.71. Calculate the K_a of saccharin.

103. Interpret Graphs The graph shows the number of millimoles (mmol) of water formed as drops of 1.0*M* HCl are added to a 25.0-mL sample of NaOH of unknown concentration.

a. Write an equation for the reaction.

b. Estimate the concentration of the NaOH.

104. Calculate Suppose you slowly add 0.1*M* NaOH to 50.0 mL of 0.1*M* HCl. What volume of NaOH must you add before neutralization will occur? Explain your reasoning.

105. Predict Will the resulting solutions be neutral, acidic, or basic at the equivalence point for each of the following titrations? Explain.

a. HCl titrated with NaOH
b. NaOH titrated with HCl
c. CH_3COOH titrated with NaOH
d. NH_3 titrated with HCl
e. CH_3COOH titrated with NH_3

***106. Use Models** You can use the following expression to find the pH of a solution:

$$pH = -\log[H^+]$$

What expression could you use to find the analogous quantity, the pOH of a solution?

107. Apply Concepts Milk, an aqueous emulsion, has a pH of about 6.7. Calculate the pOH of milk using the equation you derived in Question 106. If the equation you derived is correct, the sum of the values for pH and pOH will equal 14.

108. Apply Concepts Use the expression for K_w to demonstrate the following relationship:

$$pH + pOH = 14$$

Enrichment

109. Calculate What is the pH of a 0.010*M* solution of NaCN ($K_b = 2.1 \times 10^{-5}$)?

***110. Make Generalizations** Show that for any conjugate acid-base pair, $K_a \times K_b = K_w$.

111. Interpret Data The K_w of water varies with temperature, as shown in the table.

Temperature (°C)	K_w	pH
0	1.137×10^{-15}	a. ____
10	2.917×10^{-15}	b. ____
20	6.807×10^{-15}	c. ____
30	1.469×10^{-14}	d. ____
40	2.917×10^{-14}	e. ____
50	5.470×10^{-14}	f. ____

a. Calculate the pH of water for each temperature in the table.
b. Use the data to prepare a graph of pH versus temperature. Use the graph to estimate the pH of water at 5°C.
c. At what temperature is the pH of water approximately 6.85?

112. Calculate What is the molarity of an H_2SO_4 solution if 80.0 mL of the solution reacts with 0.424 g Na_2CO_3?

$$H_2SO_4(aq) + Na_2CO_3(aq) \longrightarrow H_2O(l) + CO_2(aq) + Na_2SO_4(aq)$$

***113. Apply Concepts** The hydrogen carbonate ion–carbonic acid buffer system is an important buffer system in the blood. This system is represented by the following equations:

$$H_2O(l) + CO_2(g) \rightleftharpoons H_2CO_3(aq)$$
$$H_2CO_3(aq) \rightleftharpoons H^+(aq) + HCO_3^-(aq)$$

Reactions in cells produce carbon dioxide. Excess carbon dioxide is released through the lungs. How could rapid breathing lead to an abnormally high blood pH (alkalosis)? How could slow breathing lead to an abnormally low blood pH (acidosis)?

114. Calculate Household bleach is a solution of sodium hypochlorite. What is the $[OH^-]$ in an aqueous solution that is 5.0% NaClO by mass? What is the pH of the solution? (The density of the solution is 1.0 g/mL, and $K_a = 3.5 \times 10^{-8}$.)

Write About Science

115. Research The main cause of tooth decay is the weak acid lactic acid (C_2H_5OCOOH). Lactic acid forms when bacteria, such as *Streptococcus mutans*, feed on sugar. In the mouth, sugars are present in the sticky plaque on tooth surfaces. Starting with the information on page R30, research current efforts to fight tooth decay. Write a report summarizing your findings.

116. Connect to the BIGIDEA Hypochlorite salts are used to disinfect swimming pools. On page R30 in the Elements Handbook, read about what happens when chlorine compounds are added to pool water. Use hydrolysis reactions to explain how the pH of the water affects the concentration of hypochlorous acid (HOCl).

CHEMYSTERY

Paper Trail

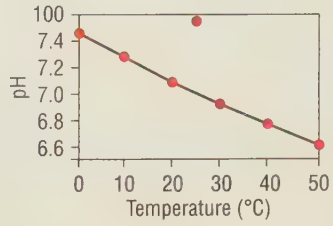
The wood pulp used to make paper is a suspension of cellulose fibers in water. Wood chips can be ground into a pulp. This is the process used to make newsprint. For higher-quality paper, the pulp is treated chemically to remove parts of the wood other than cellulose.

The paper is often coated with a chemical such as aluminum sulfate to keep it from absorbing too much ink. The chemicals that were used for this purpose often left a residue of acid in the paper. Over time, the acid caused the cellulose fibers to decay.

117. Infer The process of treating the paper is called deacidification. The first step in a popular deacidification method is to immerse the paper in a dilute solution of calcium hydroxide. Write a chemical equation to describe what occurs in this deacidification step.

***118. Connect to the BIGIDEA** What type of reaction is performed in the process of deacidification? Would you expect the pH of the paper to be raised or lowered in the process of deacidification?

Answers



ENRICHMENT

109. pH = 10.66

110.

$$K_w = K_w = \frac{[H^+][A^-]}{[HA]} \times \frac{[HA][OH^-]}{[A^-]} = [H^+][OH^-]$$

111. a. 7.4721, 7.2675, 7.0835, 6.9165, 6.7675, 6.6310

b. 7.37
c. 35°C

112. $5.00 \times 10^{-2} M$

113. Hyperventilation releases CO_2. The equilibrium shift causes H_2CO_3 and H^+ concentrations to decrease. The loss of H^+ increases the basicity of the blood and alkalosis results. Hypoventilation does not release enough CO_2. The CO_2 build up increases the H_2CO_3 and H^+ concentrations. The H^+ concentration increases the acidity of the blood and acidosis results.

114. $[OH^-] = 4.4 \times 10^{-4} M$ pH = 10.66

WRITE ABOUT SCIENCE

115. To fight tooth decay, reduce sugar intake; brush and floss regularly; use a fluoride toothpaste or rinse; and have regular dental checkups.

116. Students should note that the pH affects the relative concentrations of ClO^- and HClO in pool water. If the pH of the water is too high, solid sodium hydrogen sulfate can be used to lower the pH. If the pH is too low, sodium carbonate can be used to neutralize some of the acid.

CHEMYSTERY

START A CONVERSATION Have students reread CHEMystery. Call on volunteers to summarize why the wood-based paper tended to yellow and crack over time. **Ask** How did chemical reactions cause the paper to become crumbly? *(An acid used in the production of the paper reacted with the cellulose, causing the fibers to decay.)*
Ask Why don't the books made of rag-based paper become crumbly? Rag-based paper is acid-free.

CHEMYSTERY ANSWERS

117. $H_2SO_4 + Ca(OH)_2 \rightarrow CaSO_4 + 2H_2O$

118. BIGIDEA Deacidificaiton involves a double-replacement reaction, during which the pH increases.

Cumulative Review

119. a. $K_2O(s)$
b. $CaS(s)$
c. $AlF_3(s)$
120. 131 gO_2
121. liquid
122. The total pressure in a mixture of gases is equal to the sum of the partial pressures of each gas in the mixture.
123. b. Boyle's law
124. suspension
125. c. $SiO_2(s)$
126. hydrogen bond
127. 2.25 g KCl
128. Dissolve 0.272 mol KOH(s) in water and add sufficient water to give 400.0 mL of solution.
129. 0.49 L
130. b, c, and d
131. 1.8×10^4 J
132. a. 144 J
b. 1.0×10^3 kJ
c. 82.9 cal
133. 2.8 kJ
134. The product of the concentrations of two ions must be greater than the solubility product.
135. a. $K_{eq} = \dfrac{[CO]^2 \times [O_2]}{[CO_2]^2}$
b. $K_{eq} = \dfrac{[NH_3]^2}{[N_2] \times [N_2]^3}$
136. 2.0×10^{-8} *M*
137. a. NaCl(*aq*)
b. $CO_2(g)$
c. hot water
138. a. shift right
b. no change
c. shift right
d. shift right
e. shift rght
139. A: first order
B: second order
C: zero order overall: third order

Cumulative Review

119. Write the product of each of these combination reactions.
a. $K(s) + O_2(g) \longrightarrow$
b. $Ca(s) + S(s) \longrightarrow$
c. $F_2(g) + Al(s) \longrightarrow$

120. How many grams of oxygen are needed to completely burn 87.4 g of sulfur to form sulfur trioxide?

$$S(s) + O_2(g) \longrightarrow SO_3(g)$$

***121.** Which state of matter is not part of the process of sublimation?

122. State Dalton's law of partial pressures.

123. Which of these laws describes an inverse relationship?
a. Charles's law
b. Boyle's law
c. Gay-Lussac's law

124. Which has the largest particles, a solution, a colloid, or a suspension?

125. Which of these is not an electrolyte?
a. NaCl(*l*)
b. $KNO_2(aq)$
c. $SiO_2(s)$
d. NaCl(*aq*)

***126.** What type of bond is responsible for water's high surface tension?

127. How many grams of potassium chloride are in 45.0 mL of a 5.00% (by mass) solution?

128. How would you prepare 400.0 mL of a 0.680*M* KOH solution?

***129.** How many liters of 8.0*M* HCl are needed to prepare 1.50 L of 2.5*M* HCl?

130. Which of these is an endothermic process? Provide an explanation.
a. burning wax
b. evaporating water
c. melting wax
d. roasting a marshmallow

131. How many joules of heat are required to melt a 55.0-g ice cube at 0°C?

***132.** Make the following conversions:
a. 34.5 cal to joules
b. 250 Cal to kilojoules
c. 0.347 kJ to calories

133. The specific heat capacity of iron is 0.46 J/(g·°C). How many kilojoules of energy are needed to raise the temperature of a 432-g iron bar 14°C?

134. What must be true about the concentration of two ions if precipitation occurs when solutions of the two ions are mixed?

135. Write an equilibrium-constant expression for each equation.
a. $2CO_2(g) \rightleftharpoons 2CO(g) + O_2(g)$
b. $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$

136. What is the equilibrium concentration of barium ion in a 1.0-L saturated solution of $BaCO_3$ to which 0.25 mol K_2CO_3 has been added?

***137.** In each pair, which has the higher entropy?
a. NaCl(*s*) or NaCl(*aq*)
b. $CO_2(s)$ or $CO_2(g)$
c. hot water or cold water

138. How would each change affect the position of equilibrium of this reaction?

$$2H_2(g) + O_2(g) \rightleftharpoons 2H_2O(g) + \text{heat}$$

a. increasing the pressure
b. adding a catalyst
c. increasing the concentration of $H_2(g)$
d. cooling the reaction mixture
e. removing water vapor from the container

139. For the reaction $A(g) + B(g) + C(g) \longrightarrow D(g)$, the following data were obtained at a constant temperature. From the data, determine the order of reaction with respect to A, B, and C, and the overall order of reaction.

Initial [A] (mol/L)	Initial [B] (mol/L)	Initial [C] (mol/L)	Initial rate (mol/[L·min])
0.0500	0.0500	0.0100	6.25×10^{-3}
0.1000	0.0500	0.0100	1.25×10^{-2}
0.1000	0.1000	0.0100	5.00×10^{-2}
0.0500	0.0500	0.0200	6.25×10^{-3}

Standardized Test Prep for Indiana

Standards: C.8.4, C.8.5

Select the choice that best answers each question or completes each statement.

1. If an acid has a measured K_a of 3×10^{-6},
   (A) the acid is a strong acid.
   (B) an aqueous solution of the acid would have a pH < 7.
   (C) the acid is a strong electrolyte.
   (D) All of the above are correct.

2. The pH of a sample of orange juice is 3.5. A sample of tomato juice has a pH of 4.5. Compared to the $[H^+]$ of orange juice, the $[H^+]$ of tomato juice is
   (A) 1.0 times higher. (C) 10 times higher.
   (B) 10 times lower. (D) 1.0 times lower.

Tips for Success

Eliminate Wrong Answers If you don't know which choice is correct, eliminate those you know are wrong. If you can rule out some choices, you'll increase your chances of choosing the correct answer.

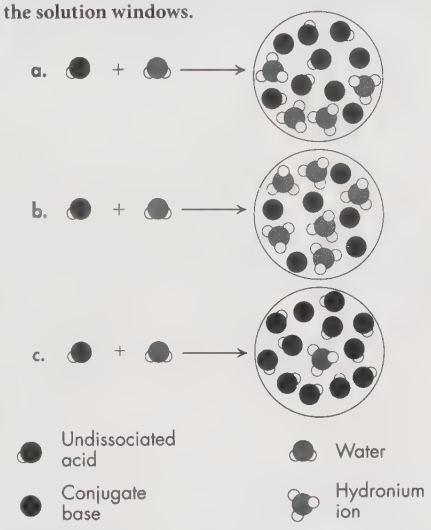
3. Which ion or molecule is the conjugate base of the ammonium ion, NH_4^+?
   (A) H_2O (B) OH^- (C) NH_3 (D) H_3O^+

4. How many moles of NaOH are required to neutralize 2.4 mol H_2SO_4?
   (A) 1.2 mol (B) 2.4 mol (C) 3.6 mol (D) 4.8 mol

5. A solution with a hydrogen-ion concentration of $2.3 \times 10^{-8} M$ has a pH between
   (A) 2 and 3. (B) 3 and 4. (C) 7 and 8. (D) 8 and 9.

6. The net ionic equation for the neutralization reaction between solutions of potassium hydroxide and hydrochloric acid is
   (A) $H^+(aq) + OH^-(aq) \longrightarrow H_2O(l)$
   (B) $KOH(aq) + HCl(aq) \longrightarrow H_2O(l) + KCl(aq)$
   (C) $K^+(aq) + Cl^-(aq) \longrightarrow KCl(aq)$
   (D) $K^+(aq) + OH^-(aq) + H^+(aq) + Cl^-(aq) \longrightarrow KCl(aq) + H_2O(l)$

7. Calculate the molarity of an HCl solution if 25.0 mL of the solution is neutralized by 15.5 mL of 0.800*M* NaOH.
   (A) 0.248*M* (B) 0.496*M* (C) 1.29*M* (D) 0.645*M*



8. Which combination of compound and ion would not make a useful buffer solution?
   (A) ammonium ion and ammonia
   (B) hydrogen carbonate ion and carbonic acid
   (C) sulfate ion and sulfuric acid
   (D) ethanoate ion and ethanoic acid

The lettered choices below refer to Questions 9–11. In each formula, P is the cation, and Q is the anion.
(A) PQ (B) P_2Q_3 (C) PQ_3 (D) PQ_2

Which of the choices is the general formula for the salt formed in each of the following neutralization reactions?

9. $H_3PO_4 + NaOH \longrightarrow$
10. $H_2SO_4 + Mg(OH)_2 \longrightarrow$
11. $HNO_3 + Al(OH)_3 \longrightarrow$

Use the drawings below to answer Questions 12 and 13. Water molecules have been omitted from the solution windows.

12. Rank the acids in order of increasing strength.
13. How many of the acids are strong acids?

Materials List

For the Student

Quick Lab, p 699
- spot plates
- medicine droppers
- liquid and powder bleach
- 3% H_2O_2
- 1% oxalic acid
- 0.2*M* $Na_2S_2O_3$, I_2 in KI(*aq*)
- $KMnO_4$(*aq*)
- grape juice
- rusty water
- colored fabric
- grass-stained fabric
- flower petals

Small-Scale Lab, p 717
- reaction surfaces
- 1.0*M* HCl, HNO_3, and H_2SO_4
- pieces of Zn, Mg, Cu, and Fe

For the Teacher

Teacher Demo, p 693
- 3 g copper(II) oxide (CuO)
- 3 g charcoal (C)
- crucible with cover
- Bunsen burner
- tongs
- glass plate

Teacher Demo, p 703
- 100 mL of 0.1*M* lead(II) acetate [$Pb(CH_3COO)_2$]
- 150-mL beaker
- 1-cm × 3-cm zinc strip
- sodium sulfide
- 3*M* NaOH
- 1*M* iron(III) chloride
- stirring rod
- plastic container

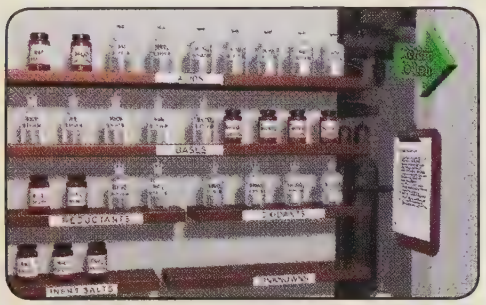
Class Activity, p 705
- 3 small glass test tubes
- zinc
- copper
- magnesium
- 0.1*M* HCl
- medicine dropper or pipet

Teacher Demo, p 710
- 6 crystals of potassium permanganate ($KMnO_4$)
- 540 mL of water, large beaker
- 1 g sodium hydrogen sulfite ($NaHSO_3$)
- two 50-mL beakers
- 1 g barium chloride dihydrate ($BaCl_2 \cdot 2H_2O$)
- 3*M* H_2SO_4
- stirring rod
- plastic container

Class Activity, p 713
- potatoes
- apples
- beakers
- water
- boiled water
- lemon juice
- carbonated beverage
- sugar
- salt
- vinegar solutions
- paper towels

Additional Digital Resources

Online Student Edition
Online Teacher's Edition
20.2 Virtual Chem Lab 30: Redox Titrations: Determination of Iron
Redox Titrations: Determining the Purity of a Sample



What's Online

CHEM TUTOR Students access guided, step-by-step tutorials for solving various oxidation-reduction problems.

PROBLEM SETS Students can practice key problem-solving skills in an online problem set.

MATH HELP Identify the students that struggle with math by assigning an online math skills diagnostic test. These students can then improve and practice math skills by using the MathXL tutorial system.

VIRTUAL LAB Students go on an animated virtual lab tour in which redox titrations are studied in a simulated laboratory environment.

KINETIC ART Students watch animations of selected figures from the chapter followed by questions to check for understanding.

CONCEPTS IN ACTION Students watch an overview of a key chapter concept using real-world contexts and concrete examples and analogies. Each activity includes an interactive animation followed by analysis questions.

690

The color of the Statue of Liberty is the result of the copper in her outer shell reacting with water, carbon dioxide, and other compounds in the air.

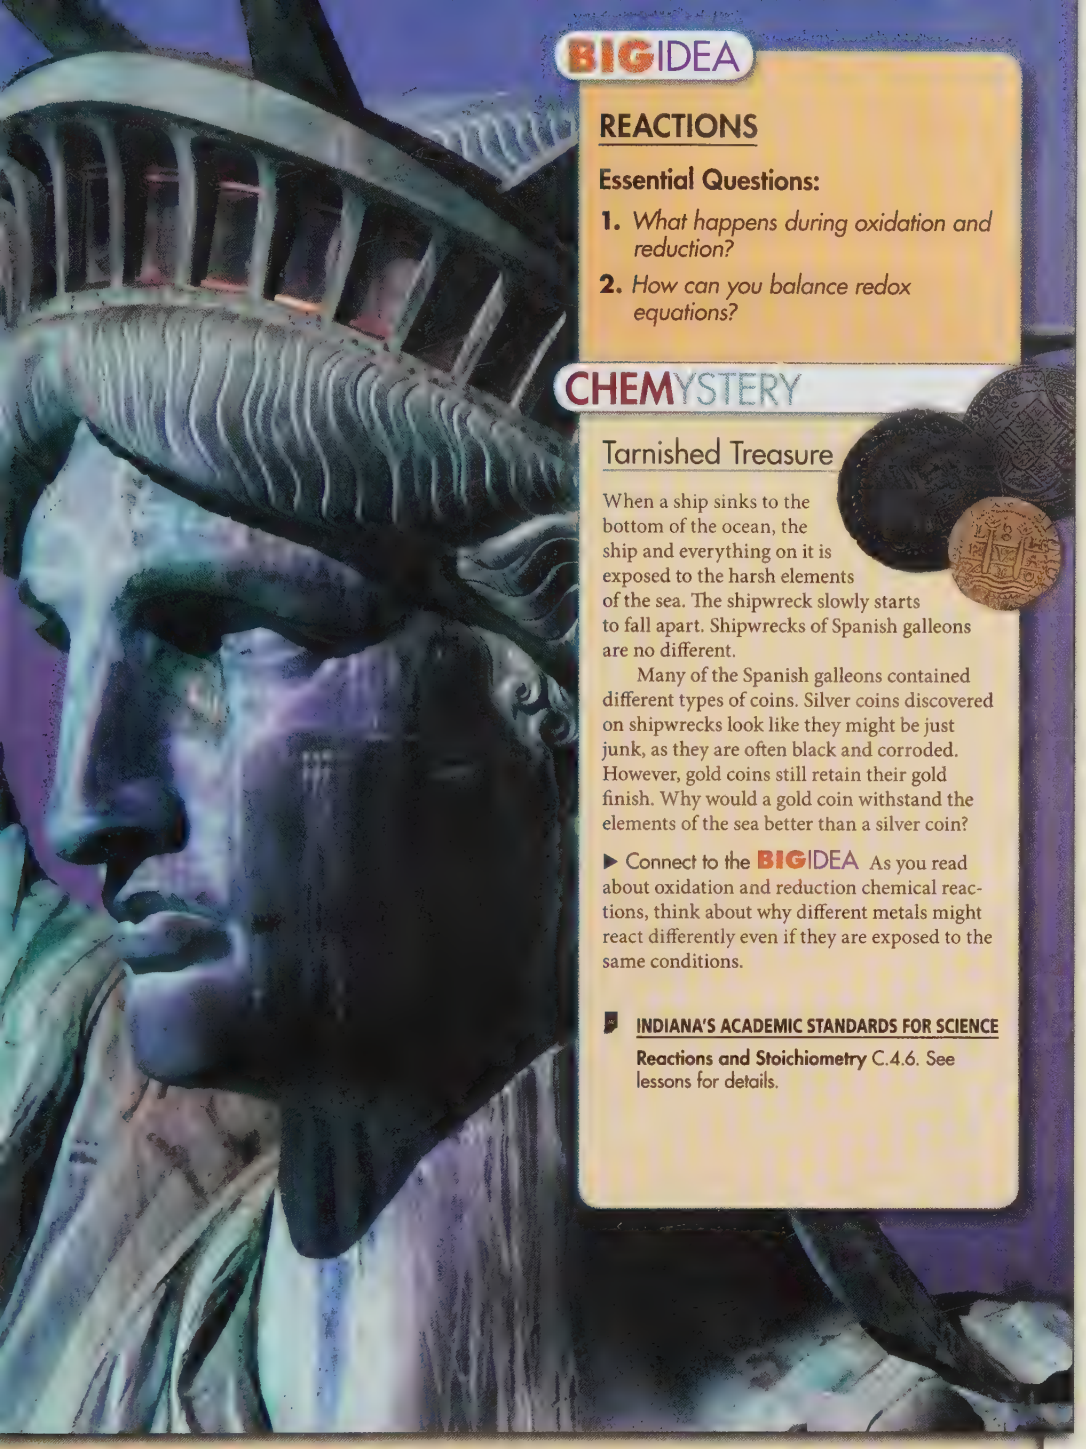
IN ACADEMIC STANDARDS for SCIENCE

Nature of Science

- Develop explanations based on reproducible data and observations gathered during laboratory investigations.
- Clearly communicate their ideas and results of investigations verbally and in written form using tables, graphs, diagrams, and photographs.

Standard 4: Reactions and Stoichiometry

C.4.6 Determine oxidation states and identify the substances gaining and losing electrons in redox reactions.



Focus on ELL

1 CONTENT AND LANGUAGE Write the chapter title on the board. Below the title, write the word *redox* from the title of Lesson 20.3. Slowly read the words aloud, taking care to enunciate the prefixes in *oxidation* and *reduction*. Convey that the word *redox* is a simpler way to say *oxidation-reduction*.

BEGINNING: LOW/HIGH Use colored markers to combine the words *oxidation-reduction* to form the word *redox*. Have students share simple words in their native language that are the combination of two larger words.

INTERMEDIATE: LOW/HIGH Write simplified English definitions of the words *oxidation* and *reduction* and present them to the class.

ADVANCED: LOW/HIGH Have students look up *oxidation* and *reduction* in a dictionary and use the definitions to predict what they will learn in each lesson.

BIG IDEA

REACTIONS

Essential Questions:

1. *What happens during oxidation and reduction?*
2. *How can you balance redox equations?*

CHEMYSTERY

Tarnished Treasure

When a ship sinks to the bottom of the ocean, the ship and everything on it is exposed to the harsh elements of the sea. The shipwreck slowly starts to fall apart. Shipwrecks of Spanish galleons are no different.

Many of the Spanish galleons contained different types of coins. Silver coins discovered on shipwrecks look like they might be just junk, as they are often black and corroded. However, gold coins still retain their gold finish. Why would a gold coin withstand the elements of the sea better than a silver coin?

▶ Connect to the BIG IDEA As you read about oxidation and reduction chemical reactions, think about why different metals might react differently even if they are exposed to the same conditions.

INDIANA'S ACADEMIC STANDARDS FOR SCIENCE

Reactions and Stoichiometry C.4.6. See lessons for details.

Introduce the Chapter

IDENTIFY PRECONCEPTIONS Students may incorrectly interpret redox reactions in terms of unrelated everyday experiences. Use the activity below to encourage them to consider chemical explanations for changes they see in their everyday life. (Note: this activity requires the treated metal to sit overnight for the results to develop.)

Activity *You will need some corroded and pitted nickels and pennies, some shiny strips of nickel and copper metal, and some clear nail polish.* Allow students to observe the coins. **Ask** What do you think caused the differences between the coins and the metal strips? *(Students may say the corroded coins are just old, have been damaged by misuse, or have something on them.)* Have students coat half of each shiny metal strip with nail polish. After the polish dries, have students place the metal strips in water and then set them on a paper towel to dry overnight. The next day, students will observe that only the uncoated portions of the strips corroded.

UbD

Understanding by Design

Students are building toward describing what happens during oxidation and reduction, using their knowledge of chemical reactions.

PERFORMANCE GOALS At the end of Chapter 20, students will be able to answer the essential questions by applying their knowledge of oxidation and reduction. Students will also be able to identify redox reactions.

ESSENTIAL QUESTIONS Read the essential questions aloud. **Ask** What do you think *oxidation* and *reduction* mean? *(Students may say that oxidation is related to oxygen and that reduction is related to decreasing.)* Caution students that sometimes names have historical meanings that are no longer accurate. **Ask** How do you balance an equation, based on conservation of mass? *(The number of atoms of each element must be the same in the reactants and the products.)* Tell students that in this chapter they will learn a different way to balance equations.

BIG IDEA Use the photo of the Statue of Liberty to help students connect to the concepts they will learn in this chapter. Activate prior knowledge by asking students who have visited the Statue of Liberty to describe its color. Point out that the statue is made of copper, which naturally has a reddish-brown color. Explain that a chemical reaction changed the outer layer of copper to the green patina. **Ask** What are other examples of chemical reactions changing the outer layer of a metal object? *(Sample answers: A bike left outside rusts; silverware tarnishes.)* Discuss conditions students have noticed when these changes occur.

CHEMYSTERY Have students read over the CHEMystery. Connect the CHEMystery to the Big Idea of Reactions by reminding students that whether a reaction occurs depends on the types of elements involved. It also depends on the environment of the elements. Because silver and gold are in the same group on the periodic table, they have the same outer electron configuration, but their tendencies to react are different. Have students predict how this might cause silver to corrode but gold to retain its finish in the underwater conditions.

LESSON 20.1

Key Objectives

20.1.1 DESCRIBE what happens to a substance that undergoes oxidation and a substance that undergoes reduction.

20.1.2 EXPLAIN how the presence of salts and acids accelerates the corrosion of metals.

Additional Resources

Engage

CHEMISTRY & YOU Have students read the opening paragraph. **Ask** What are some ways that you can protect a car against this type of corrosion? *(Put a protective undercoat on the car or use plastic car parts.)*

Activate Prior Knowledge

Review the concept of valence electrons. Then assess students' knowledge about electron transfer. **Ask** What happens to magnesium and oxygen when they react to form magnesium oxide, MgO? *(Mg loses electrons to form Mg^{2+}, and oxygen gains electrons to form O^{2-}.)*

IN ACADEMIC STANDARDS for SCIENCE

- Develop explanations based on reproducible data and observations gathered during laboratory investigations.

C.4.6 Determine oxidation states and identify the substances apparently gaining and losing electrons in redox reactions.

20.1 The Meaning of Oxidation and Reduction

C.4.6 Redox reactions

CHEMISTRY & YOU

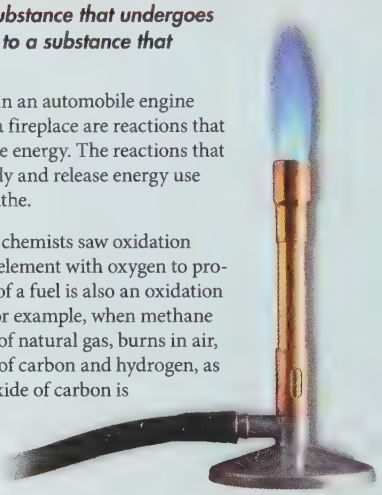
Q: *Why do you need to wash the bottom of your car?* A clean car may look better than a dirty car, but looks aren't the only reason to wash your car. During winter in cold climates, salt is often spread on roads to lower the freezing point of water and thereby prevent the buildup of slippery ice. Salt may make driving safer, but the salt that clings to the metallic parts of cars can cause damage to your car. In this lesson, you will learn about oxidation-reduction reactions, including those that damage salty cars by causing them to corrode or rust relatively quickly.

Key Questions

What happens to a substance that undergoes oxidation? What happens to a substance that undergoes reduction?

How does the presence of salts and acids accelerate the corrosion of metals?

Vocabulary



- oxidation-reduction reactions
- oxidation
- reduction
- reducing agent
- oxidizing agent

What Are Oxidation and Reduction?

What happens to a substance that undergoes oxidation? What happens to a substance that undergoes reduction?

The combustion of gasoline in an automobile engine and the burning of wood in a fireplace are reactions that require oxygen as they release energy. The reactions that break down food in your body and release energy use oxygen from the air you breathe.

Oxygen and Redox Early chemists saw oxidation only as the combining of an element with oxygen to produce an oxide. The burning of a fuel is also an oxidation reaction that uses oxygen. For example, when methane (CH_4), the main component of natural gas, burns in air, it oxidizes and forms oxides of carbon and hydrogen, as shown in Figure 20.1. One oxide of carbon is carbon dioxide, CO_2.

See Oxidation animated online.

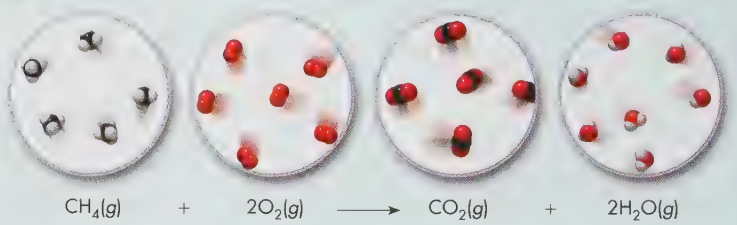


Figure 20.1
Oxidation of Methane
In a Bunsen burner, oxygen from the air is mixed with methane from the gas line. The methane is oxidized, and carbon dioxide and water are produced.

Focus on ELL

1 CONTENT AND LANGUAGE Write the word *reduction* on the board and pronounce it slowly. Explain that this term comes from the Latin word *reducere*, meaning "to lead back." Have students brainstorm phrases that refer to reductions, and help them connect the concept of reduction with a decrease in something, such as mass or volume.

2 FRONTLOAD THE LESSON Ask students if they have ever worn jewelry that turned their skin green or had jewelry that turned dark. Explain that these color changes are the result of oxidation-reduction reactions, and both reactions were related to the metals' ability to lose electrons—also known as their reactivities.

3 COMPREHENSIBLE INPUT On the board, rewrite the redox reaction from page 695 by using electron dot structures with different colors for the Mg and S electrons. Then draw the arrows showing the transfer of electrons. Use the Kinetic Art activity to reinforce the discussion on corrosion.

Not all oxidation processes that use oxygen involve burning. For example, when elemental iron turns to rust as in Figure 20.2, it slowly oxidizes to compounds such as iron(III) oxide (Fe_2O_3). Bleaching stains in fabrics is another example of oxidation that does not involve burning. Common liquid household bleach contains sodium hypochlorite (NaClO), a substance that releases oxygen, which oxidizes stains to a colorless form. Powder bleaches may contain calcium hypochlorite ($Ca(ClO)_2$), sodium perborate ($NaBO_3$), or sodium percarbonate ($2Na_2CO_3 \cdot 3H_2O_2$). Hydrogen peroxide (H_2O_2) also releases oxygen when it decomposes. It is both a bleach and a mild antiseptic that kills bacteria by oxidizing them.

A process called reduction is the opposite of oxidation. Originally, reduction meant the loss of oxygen from a compound. The reduction of iron ore to metallic iron involves the removal of oxygen from iron(III) oxide. The reduction is accomplished by heating the ore with carbon, usually in the form of coke. The equation for the reduction of iron ore is shown below.

$$\underset{\text{Iron(III) oxide}}{2Fe_2O_3(s)} + \underset{\text{Carbon}}{3C(s)} \longrightarrow \underset{\text{Iron}}{4Fe(s)} + \underset{\text{Carbon dioxide}}{3CO_2(g)}$$

The reduction of iron also includes an oxidation process. As iron(III) oxide is reduced to iron by losing oxygen, carbon oxidizes to carbon dioxide by gaining oxygen. Oxidation and reduction always occur simultaneously. **A substance that undergoes oxidation gains oxygen. A substance that undergoes reduction loses oxygen.** No oxidation occurs without reduction, and no reduction occurs without oxidation. Reactions that involve the processes of oxidation and reduction are therefore called **oxidation-reduction reactions.** Oxidation-reduction reactions are also known as *redox reactions.*

Figure 20.2 Oxidation of Iron
When items made of iron are exposed to moist air, the Fe atoms react with O_2 molecules. The iron rusts; it is oxidized to compounds such as iron(III) oxide (Fe_2O_3).

Differentiated Instruction

L3 ADVANCED STUDENTS Have advanced students do research on redox reactions involving oxygen that are important in nature. Examples are the reduction of carbon in carbon dioxide to form carbohydrates during photosynthesis and the oxidation of glucose during cell respiration to release energy. Have students prepare reports or posters based on their research.

L1 SPECIAL NEEDS STUDENTS Give each student two index cards, one with a large + symbol and the other with a large – symbol. To assess students' understanding, tell them to answer reduction questions by holding up the + card to represent a gain in electrons and to answer oxidation questions by holding up the – card to represent a loss of electrons.

Foundations for Reading

BUILD VOCABULARY Use a web diagram to connect the vocabulary terms. Place the terms *oxidation-reduction reactions* and *redox reactions* in the center, and then place the four remaining terms around the center, along with an explanation of how the terms relate.

READING STRATEGY Have students preview the lesson content by creating an outline using the orange and blue section headings.

Explain

What Are Oxidation and Reduction?

START A CONVERSATION Recall the electron structure of an oxygen atom and how oxygen atoms bond with other atoms. Be sure to identify the source of the electrons an oxygen atom gains during bonding. **Ask** When a metal combines with oxygen, does the metal gain or lose electrons? *(It loses electrons.)* **Ask** When oxygen is removed from the oxide of a metal, does the metal gain or lose electrons? *(It gains electrons.)* Explain to students that this information is what led to the broader definition of *oxidation and reduction* as an exchange of electrons.

Explore

Teacher Demo

PURPOSE Students will observe how pure metals are obtained from their oxide ores by reduction.

MATERIALS 3 g copper(II) oxide (CuO), 3 g charcoal (C), crucible with cover, Bunsen burner, tongs, glass plate

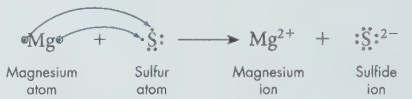
PROCEDURE Mix 3 g copper(II) oxide (CuO) and 3 g charcoal (C) in a crucible. Cover the crucible. Then heat strongly and evenly over a Bunsen burner for 10 minutes. Cool the crucible and remove the copper with tongs. Pass the copper around on a glass plate for the students to examine. Pass around a bit of the original CuO as well so that the students can see the change in appearance. On the board, write the reaction that occurred: $2CuO(s) + C(s) + 2Cu(s) \rightarrow CO_2(g)$. **Ask** Based on loss or gain of oxygen, what species were oxidized and reduced? *(C was oxidized and CuO was reduced.)*

EXPECTED OUTCOME Copper metal is formed.

Explore

USE AN ANALOGY To reinforce the dual nature of redox reactions, compare redox reactions to acid-base reactions. Explain that the transfer of electrons from a reducing agent to an oxidizing agent is analogous to the transfer of protons from acids to bases. In neither case can the donor act independently from an acceptor.

Extend



Connect to PHYSICAL CHEMISTRY

Show students how to construct Born-Haber cycles for the redox reactions of sodium and magnesium with oxygen by finding tabulated energy values for the heats of formation of MgO and Na_2O; heats of vaporization of Mg(*s*) and Na(*s*); heat of forming O atoms from O_2; ionization energies of gaseous Mg and Na; and the electron affinity of O. *(From their diagrams, the students should be able to determine the lattice energies of MgO and Na_2O. Large lattice energies indicate that these redox reactions are highly exothermic.)*

Electron Shift in Redox Reactions The modern concepts of oxidation and reduction have been extended to include many reactions that do not even involve oxygen. You learned in Chapter 6 that, with the exception of fluorine, oxygen is the most electronegative element. As a result, when oxygen bonds with an atom of a different element (other than fluorine), electrons from that atom shift toward oxygen. Redox reactions are currently understood to involve any shift of electrons between reactants. **Oxidation** is now defined to mean complete or partial loss of electrons or gain of oxygen. **Reduction** is now defined to mean complete or partial gain of electrons or loss of oxygen.

Oxidation	Reduction
Loss of electrons	Gain of electrons
Gain of oxygen	Loss of oxygen

Redox Reactions That Form Ions During a reaction between a metal and a nonmetal, electrons are transferred from atoms of the metal to atoms of the nonmetal. For example, when magnesium metal is heated with the nonmetal sulfur, the ionic compound magnesium sulfide is produced as shown in Figure 20.3. Two electrons are transferred from a magnesium atom to a sulfur atom. The magnesium atoms are made more stable by the loss of electrons. The sulfur atoms become more stable due to the gain of electrons.

Because it loses electrons, the magnesium atom is said to be oxidized to a magnesium ion. Simultaneously, the sulfur atom gains two electrons and is reduced to a sulfide ion. The overall process is represented as the two component processes below.

Oxidation: $\cdot Mg\cdot \longrightarrow Mg^{2+} + 2e^-$ (loss of electrons)

Reduction: $\cdot\ddot{S}\cdot + 2e^- \longrightarrow :\ddot{S}:^{2-}$ (gain of electrons)

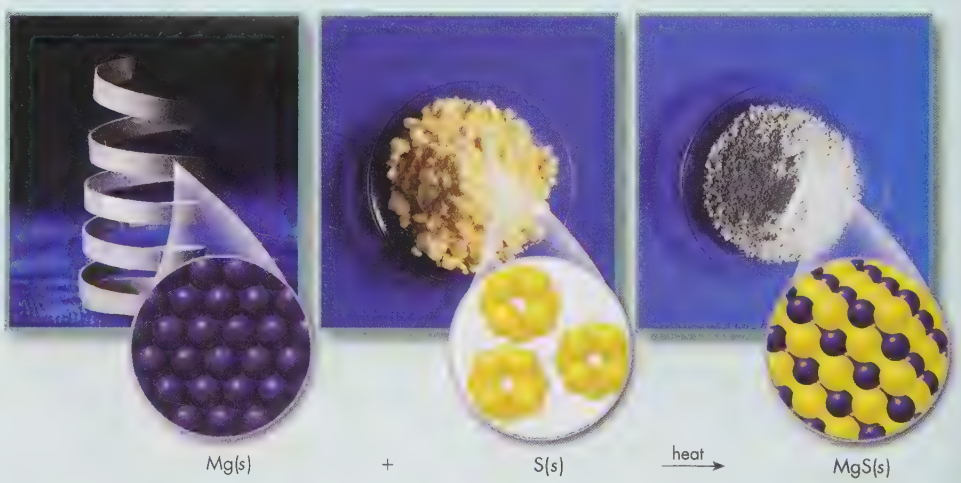


Figure 20.3
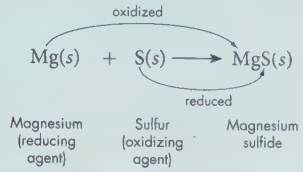
Synthesis of an Ionic Compound
When magnesium and sulfur are heated together, they undergo an oxidation-reduction reaction to form magnesium sulfide.



Professional Development Note

The History of the Word *Copper*

Reduction processes were used to produce some metals more than 5000 years ago. Copper oxide and copper sulfide ores were roasted with charcoal to form copper, carbon dioxide, and sulfur dioxide. Large amounts of copper ore were mined on the island of Cyprus, off the coast of the area now known as Turkey. The Romans, who eventually imported this valuable ore, called it *aes cyprium*, or *ore of Cyprus*. The name was later shortened to *cyprium* and then corrupted to *cuprum*. The English word *copper* derives from this corruption of the Latin word for Cyprus.

694 Chapter 20 • Lesson 1

A substance that undergoes oxidation loses electrons. A substance that undergoes reduction gains electrons. The substance that loses electrons is the **reducing agent.** By losing electrons to sulfur, magnesium reduces the sulfur. Magnesium is thus the reducing agent. The substance that accepts electrons is the **oxidizing agent.** By accepting electrons from magnesium, sulfur oxidizes the magnesium. Sulfur is the oxidizing agent. Another way to identify oxidizing and reducing agents is to remember that the species that is reduced is the oxidizing agent and the species oxidized is the reducing agent.

READING SUPPORT

Build Study Skills: *Use Mnemonics* To help you remember the definitions of *oxidation* and *reduction*, use the phrase *"LEO* the lion goes *GER."* LEO stands for Losing Electrons is Oxidation; GER stands for Gaining Electrons is Reduction.

SampleProblem 20.1

Identifying Oxidized and Reduced Reactants

Silver nitrate reacts with copper to form copper nitrate and silver. From the equation below, determine what is oxidized and what is reduced. Identify the oxidizing agent and the reducing agent.

$$2AgNO_3(aq) + Cu(s) \longrightarrow Cu(NO_3)_2(aq) + 2Ag(s)$$

1 Analyze **Identify the relevant concepts.** Identify the ions in the reaction and then trace how the electrons were transferred.

2 Solve **Apply concepts to this situation.**

Rewrite the equation in ionic form so it will be easier to analyze the reaction.

$$2Ag^+ + 2NO_3^- + Cu \longrightarrow Cu^{2+} + 2NO_3^- + 2Ag$$

In this reaction, two electrons are lost from a copper atom (Cu) when it becomes a Cu^{2+} ion. These electrons are gained by two silver ions (Ag^+), which become neutral silver atoms.

The species that loses electrons is oxidized and is the reducing agent. The species that gains electrons is reduced and is the oxidizing agent.

Oxidation: $Cu \longrightarrow Cu^{2+} + 2e^-$ (loss of electrons)
Reduction: $2Ag^+ + 2e^- \longrightarrow 2Ag$ (gain of electrons)

The Cu is the reducing agent. The Ag^+ is the oxidizing agent.

1. Determine what is oxidized and what is reduced in each reaction. Identify the oxidizing agent and reducing agent in each case.
- **a.** $2Na(s) + S(s) \longrightarrow Na_2S(s)$
- **b.** $4Al(s) + 3O_2(g) \longrightarrow 2Al_2O_3(s)$

2. Identify these processes as either oxidation or reduction.
- **a.** $Li \longrightarrow Li^+ + e^-$
- **b.** $2I^- \longrightarrow I_2 + 2e^-$
- **c.** $Zn^{2+} + 2e^- \longrightarrow Zn$
- **d.** $Br_2 + 2e^- \longrightarrow 2Br^-$

UbD Check for Understanding

What happens during oxidation and reduction?

To assess students' understanding of electron transfer during a redox reaction with ionic compounds, ask students to use a thumbs up to indicate *true* or a thumbs down to indicate *false* in response to the following statement:

A substance that undergoes oxidation becomes more negative, and a substance that undergoes reduction becomes more positive. *(false)*

ADJUST INSTRUCTION If students are having difficulty with this concept, have them review the oxidation and reduction reactions for Mg and S on the previous page. Point out that the charge on Mg becomes more positive when it loses two electrons during oxidation, while the charge on S becomes more negative. It may be helpful to plot the charges on a number line so that students can visually trace the direction of change.

Explore

PURPOSE Students will write a reaction equation and identify the oxidizing and reducing agents.

MATERIALS paper, pencil, periodic table

PROCEDURE Assign students to groups of two or three. Have one student in each group select an active metal and a nonmetal from the periodic table. Have this student ask the other student(s) to identify the ionic compound that forms when electron transfer occurs between the metal and the nonmetal. Have students write the equation for the reaction and identify the oxidizing and reducing agents.

Sample Practice Problem

Determine what is oxidized and what is reduced in the following reaction. Also identify the oxidizing agent and reducing agent.

$6Li(s) + N_2(g) \rightarrow 2Li_3N(s)$

(Li is oxidized and is the reducing agent; N is reduced and is the oxidizing agent.)

Answers

1. **a.** Na: oxidized (reducing agent)
   S: reduced (oxidizing agent)
   b. Al: oxidized (reducing agent)
   O_2: reduced (oxidizing agent)
2. **a.** oxidation
   b. oxidation
   c. reduction
   d. reduction

Explain

APPLY CONCEPTS As a class, generate supporting examples of redox reactions based on the processes listed in Table 20.1. Then, have students identify the oxidizing and reducing agents. Emphasize that for any given reaction, one or more of the processes may be in effect. Point out any such examples generated by the class. Tell students that the issue of oxidation numbers will be addressed in Lesson 20.2.

USE VISUALS Have students examine the photograph in Figure 20.4. Have a volunteer slowly read the caption aloud. On the board, write the balanced redox reaction for hydrogen burning in oxygen. Identify the reducing and oxidizing agents, and explain the identities on the basis of partial loss or gain of electrons. State that another gas, acetylene, C_2H_2, is also used in torches because it produces a large amount of heat when it burns. **Ask** What is the balanced chemical equation for this redox reaction? *($2C_2H_2(g) + 5O_2(g) \rightarrow 4CO_2(g) + 2H_2O(g)$)*

Then, have students underline the oxidizing agents and circle the reducing agents. As a class, discuss the reasoning behind students' answers.

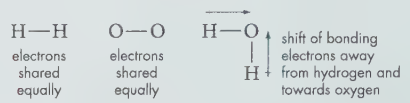


Figure 20.4 Oxyhydrogen
This welder is using an oxyhydrogen torch to cut and weld steel. When hydrogen burns in oxygen, the redox reaction generates temperatures of about 2600°C.

Redox With Covalent Compounds When a metal and a nonmetal react and form ions, it is easy to identify complete transfers of electrons. But some reactions involve covalent compounds, that is, compounds in which complete electron transfer does not occur. One example is the reaction of hydrogen with oxygen.

$$2H_2(g) + O_2(g) \longrightarrow 2H_2O(l)$$

Consider what happens to the bonding electrons in the formation of a water molecule. In each reactant hydrogen molecule, the bonding electrons are shared equally between the hydrogen atoms. In water, however, the bonding electrons are pulled toward oxygen because it is much more electronegative than hydrogen. The result is a shift of bonding electrons away from hydrogen, even though there is not a complete transfer. Hydrogen is oxidized because it undergoes a partial loss of electrons.

In oxygen, the other reactant, the bonding electrons are shared equally between oxygen atoms in the reactant oxygen molecule However, when oxygen bonds to hydrogen in the water molecule, there is a shift of electrons toward oxygen. Oxygen is thus reduced because it undergoes a partial gain of electrons.

In the reaction of hydrogen and oxygen to produce water, hydrogen is the reducing agent because it is oxidized. Oxygen is the oxidizing agent because it is reduced. This redox reaction is highly exothermic—that is, it releases a great deal of energy, as shown in Figure 20.4.

In some reactions involving covalent reactants or products, the partial electron shifts are less obvious. Some general guidelines are helpful. For example, for carbon compounds, the addition of oxygen or the removal of hydrogen is always oxidation. Table 20.1 below lists processes that constitute oxidation and reduction. The last entry in the table refers to oxidation numbers, which are introduced in Lesson 20.2.

Table 20.1

Processes Leading to Oxidation and Reduction

Oxidation	Reduction
Complete loss of electrons (ionic reactions)	Complete gain of electrons (ionic reactions)
Shift of electrons *away* from an atom in a covalent bond	Shift of electrons *toward* an atom in a covalent bond
Gain of oxygen	Loss of oxygen
Loss of hydrogen by a covalent compound	Gain of hydrogen by a covalent compound
Increase in oxidation number	Decrease in oxidation number

Developing Film

Black-and-white photography involves oxidation-reduction reactions. Exposing black-and-white film to light activates very fine grains of silver bromide in the film. The film is developed by placing it in a developing solution that is actually a reducing agent. The developer, usually an organic chemical, such as hydroquinone, $C_6H_4(OH)_2$, reduces the activated silver bromide to finely divided, black metallic silver. Any silver bromide that remains unactivated is removed from the film by using a solvent called a fixer. Sodium thiosulfate, commonly called hypo, is used for this purpose. On the film, the areas exposed to the most light appear darkest because they have the highest concentration of metallic silver. The reversed image, called a negative, is used to produce a positive print, the black-and-white photograph, of the image.

Corrosion

How does the presence of salts and acids accelerate the corrosion of metals?

Billions of dollars are spent yearly to prevent and to repair damage caused by the corrosion of metals. Iron, a common construction metal often used in the form of the alloy steel, corrodes by being oxidized by oxygen to ions of iron. Water in the environment accelerates the rate of corrosion. Oxygen, the oxidizing agent, is reduced to oxide ions (in compounds such as Fe_2O_3) or to hydroxide ions. The following equations describe the corrosion of iron to iron hydroxides in moist conditions.

$$2Fe(s) + O_2(g) + 2H_2O(l) \longrightarrow 2Fe(OH)_2(s)$$

$$4Fe(OH)_2(s) + O_2(g) + 2H_2O(l) \longrightarrow 4Fe(OH)_3(s)$$

Corrosion occurs more rapidly in the presence of salts and acids. **The presence of salts and acids accelerates corrosion by producing conductive solutions that make electron transfer easier.** The corrosion of some metals can be a desirable feature, as Figure 20.5 shows.

Resistance to Corrosion Not all metals corrode easily. Gold and platinum are called noble metals because they are very resistant to losing their electrons by corrosion. Other metals lose electrons easily but are protected from extensive corrosion by the oxide coating formed on their surface. For example, aluminum oxidizes quickly in air to form a coating of very tightly packed aluminum oxide particles. This coating protects the aluminum object from further corrosion, as shown in Figure 20.6. Iron also forms a coating when it corrodes, but the coating of iron oxide that forms is not tightly packed. Water and air can penetrate the coating and attack the iron metal beneath it. The corrosion continues until the iron object becomes only a pile of rust.

Figure 20.5 Corrosion
Oxidation-reduction reactions cause corrosion. The copper on this building reacted with water vapor, carbon dioxide, and other substances in the air to form a patina. This patina consists of a pale-green film of basic copper(II) carbonate. Patinas enhance the surface appearance of copper objects.

See corrosion animated online.

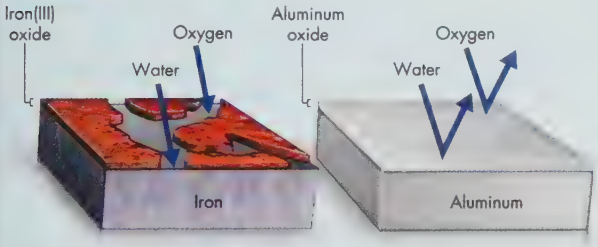

Figure 20.6 Comparing Oxides
Oxidation causes the complete corrosion of some metals. **a.** Iron reacts with water and oxygen to form iron(III) oxide, or rust. **b.** Aluminum, however, resists such corrosion because it forms a protective coating of aluminum oxide.
Apply Concepts ***How does the aluminum oxide on aluminum differ from the iron(III) oxide formed on corroding iron?***

CHEMISTRY & YOU

Q: *If your car is exposed to salt on the roads in the winter, why is it important to wash the salt off your car?*

UbD Check for Understanding

What happens during oxidation and reduction?

Assess students' knowledge of the difference between redox reactions involving ionic compounds and redox reactions involving covalent compounds by having students write a one-minute comparison of electron transfer in the two types of compounds. *(In ionic compounds, electrons are transferred between ions. In covalent compounds, there is a shift of electrons toward one of the atoms in the compound, but no electrons are actually transferred between the atoms.)*

ADJUST INSTRUCTION If students are having difficulty answering the question, have them review Table 20.1 and the preceding text, and then allow them the opportunity to revise their answers. It may be helpful to compare electron transfer between ions to passengers switching seats from one side of a bus to the other when going around a curve. Then compare passengers leaning into the curve but staying in the same seat to electrons shifting toward one atom in covalent compounds.

Explain

Corrosion

START A CONVERSATION Discuss with the class what happens if they leave a bike, skateboard, or wagon outside for a period of time. **Ask** Have you ever noticed any changes to the metal parts on these objects after they have been exposed to the weather? *(Sample answer: Yes; the parts rust.)* **Ask** Do you think all metals react the same way to long-term weather exposure? *(Answers will vary.)* Explain that rusting is a type of corrosion. Convey that many metals oxidize when exposed to the oxygen in air. **Ask** Can you identify the common chemical characteristic of all metal corrosion? *(the transfer of electrons from metals to oxidizing agents)* **Ask** What are some factors that increase the rate of corrosion? *(Sample answers: temperature, concentration of salts and acids, exposure.)* **Ask** What are some ways in which the rate of corrosion can be decreased or eliminated? *(Sample answers: Protect the objects from the weather; coat the metal parts; replace metal parts with plastic.)*

Explore

Class Activity

PURPOSE Students will order metals based on their ease of corrosion.

PROCEDURE Have students try to prepare a list of metals ordered by their ease of corrosion. Have students base their lists on known behaviors of specific metals. As a clue to metals' behavior, suggest that students consider how different metals are used. After students compile their lists, refer them to Table 11.2, the activity series for metals, on page 361. Have students write a paragraph discussing how closely their lists correspond to the actual activity series. **Ask** Why might there be discrepancies between your lists and the activity series? *(Reasons might include unavailability of data for some metals or difficulty in rating metals whose behaviors and uses are similar.)*

CHEMISTRY & YOU Salt causes metal car parts to corrode more quickly.

Answers

FIGURE 20.6 Unlike iron(III) oxide, the tough aluminum oxide coating on the surface of the metal actually protects the aluminum object from further corrosion.

Extend

Students may incorrectly assume that corrosion is always undesirable, because people spend a lot of time, money, and energy trying to prevent or inhibit the redox reaction that causes corrosion. Point out that corrosion is not always a bad thing. Explain that because the oxidation of metal is generally an exothermic reaction, it can be used to generate useful heat—as long as the oxidation takes place quickly enough to release the heat energy in a short span of time. Have students research ways in which metal oxidation can be useful to humans. Then, have them identify the reaction involved and write an equation for it. Students should also identify which reactant was oxidized and which one was reduced.

Evaluate

Informal Assessment

On the board, write several equations for redox reactions. Ask students to identify the oxidizing and reducing agents. Be sure to assess the logic students use to arrive at their answers. Then have students complete the 20.1 Lesson Check.

Reteach

Use the illustrations in this lesson as a basis for review. Starting with Figure 20.1 and continuing to Figure 20.7, question students about what is being illustrated and what is significant about it. Have students use information supplied by the captions of Figures 20.5, 20.6, and 20.7 to write redox equations for the reactions taking place in the images.

Controlling Corrosion The corrosion of objects such as shovels or knives is a common problem but not usually a serious one. In contrast, the corrosion of a steel support pillar of a bridge or the steel hull of an oil tanker is much more serious and costly. To prevent corrosion in such cases, the metal surface may be coated with oil, paint, plastic, or another metal, as shown in Figure 20.7. These coatings exclude air and water from the surface, thus preventing corrosion. If the coating is scratched or worn away, however, the exposed metal will begin to corrode.

In another method of corrosion control, one metal is "sacrificed," or allowed to corrode, to save a second metal. For example, to protect an iron object, a piece of magnesium (or another active metal) may be placed in electrical contact with the iron. When oxygen and water attack the iron object, the iron atoms lose electrons as the iron begins to be oxidized. However, because magnesium is a better reducing agent than iron, the magnesium immediately transfers electrons to the iron atoms, preventing their oxidation.

Sacrificial zinc and magnesium blocks are sometimes attached to piers and ship hulls to prevent corrosion damage in areas submerged in water. Figure 20.7b shows zinc blocks attached to the steel hull of a ship. The blocks corrode instead of the iron. Underground pipelines and storage tanks may be connected to magnesium blocks for protection. It is easier and cheaper to replace a block of magnesium or zinc than to replace a bridge or a pipeline.

Figure 20.7 Corrosion Control
Painting a surface, like the Golden Gate Bridge, protects it from the effects of the environment. **a.** Chromium metal also serves as a protective coating and imparts an attractive, mirrorlike finish. Like aluminum, chromium forms a corrosion-resistant oxide film on its surface. **b.** Zinc blocks are attached to the steel (iron) hull of this ship. The zinc blocks oxidize (corrode) instead of the iron, preventing the hull from corroding.

Learn more about corrosion online.

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the Quick Lab on the following page. Make sure each group has ELLs of varied language proficiencies so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Provide the data grid for students and model how to record the observations. Allow students to use single words or symbols in their answers.

INTERMEDIATE: LOW/HIGH Paraphrase the procedure and Analyze and Conclude questions for students. Have students generate their own questions to help them compare and contrast the oxidizing agents.

ADVANCED: LOW Pair students with writing partners for peer feedback.

HIGH Ask students to complete the Analyze and Conclude questions with written responses.

Quick Lab

Purpose To test the effect of oxidizing agents on stains and dyes

Bleach It! Oxidize the Color Away

Materials

- spot plate
- dropper
- water
- colorimeter (optional)

Oxidizing Agents

- liquid chlorine bleach (5% (m/v) sodium hypochlorite)
- powder bleach
- oxalic acid solution (1% (m/v))
- sodium thiosulfate solution (hypo) (0.2*M* $Na_2S_2O_3$)
- hydrogen peroxide (3% (v/v) H_2O_2)

Samples

- iodine solution (1% I_2 in 2% (m/v) KI)
- potassium permanganate solution (0.05*M* $KMnO_4$)
- grape juice
- rusty water
- piece of colored fabric
- colored flower petals
- grass stain on piece of white fabric

Procedure

1. Place samples on a spot plate. Use 4 drops of each liquid or a small piece of each solid.
2. Describe the color and appearance of each sample in Step 1.
3. Add a few drops of the first oxidizing agent to each sample.
4. Describe any immediate change in appearance and any further change after 15 minutes.
5. Repeat Steps 1–4 with each oxidizing agent, using a new sample for each oxidizing agent.

Analyze and Conclude

1. **Organize Data** Make a grid and record your observations.
2. **Compare and Contrast** Compare the oxidizing power of the oxidizing agents.
3. **Explain** How do you know that chemical changes have occurred?

20.1 LessonCheck

3. **Define** Define oxidation and reduction in terms of the gain or loss of oxygen.
4. **Define** Define oxidation and reduction in terms of the gain or loss of electrons.
5. **Explain** How does the presence of salts and acids accelerate the corrosion of metals?
6. **Explain** How do you identify the oxidizing agent and the reducing agent in a redox reaction?
7. **Identify** Which of the following would most likely be oxidizing agents and which would most likely be reducing agents? (*Hint:* Think in terms of tendencies to lose or gain electrons.)
   a. Cl_2 **b.** K **c.** Ag^+
8. **Apply Concepts** Use electron transfer or electron shift to identify what is oxidized and what is reduced in each reaction. Use the electronegativity values in Table 6.2 in Chapter 6, for covalent compounds.
   a. $2Na(s) + Br_2(l) \longrightarrow 2NaBr(s)$
   b. $H_2(g) + Cl_2(g) \longrightarrow 2HCl(g)$
   c. $2Li(s) + F_2(g) \longrightarrow 2LiF(s)$
   d. $S(s) + Cl_2(g) \longrightarrow SCl_2(g)$
   e. $N_2(g) + 2O_2(g) \longrightarrow 2NO_2(g)$
   f. $Mg(s) + Cu(NO_3)_2(aq) \longrightarrow Mg(NO_3)_2(aq) + Cu(s)$
9. **Identify** For each reaction in Problem 8, identify the reducing agent and the oxidizing agent.

Lesson Check Answers

3. Oxidation is the gain of oxygen. Reduction is the loss of oxygen.
4. Oxidation is the loss of electrons. Reduction is the gain of electrons.
5. Salts and acids produce conductive solutions that make electron transfer easier.
6. The species reduced is the oxidizing agent. The species oxidized is the reducing agent.
7. **a.** oxidizing agent **b.** reducing agent **c.** both
8. **a.** Na oxidized; Br_2 reduced **b.** H_2 oxidized; Cl_2 reduced **c.** Li oxidized; F_2 reduced **d.** S oxidized; Cl_2 reduced **e.** N_2 oxidized; O_2 reduced **f.** Mg oxidized; Cu reduced
9. **a.** reducing agent, Na; oxidizing agent, Br_2
   b. reducing agent, H_2; oxidizing agent, Cl_2
   c. reducing agent, Li; oxidizing agent, F_2
   d. reducing agent, S; oxidizing agent, Cl_2
   e. reducing agent, N_2; oxidizing agent, O_2
   f. reducing agent, Mg; oxidizing agent, Cu

Explore

Quick Lab

OBJECTIVE After completing this activity, students will be able to test the effect of oxidizing agents on stains and dyes.

SKILLS FOCUS observing, comparing, drawing conclusions

PREP TIME 20 minutes

MATERIALS spot plates, medicine droppers, liquid and powder bleach, 3% H_2O_2, 1% oxalic acid, 0.2*M* $Na_2S_2O_3$, I_2 in KI(*aq*), $KMnO_4$(*aq*), grape juice, rusty water, colored fabric, grass-stained fabric, flower petals

ADVANCE PREPARATION Prepare the oxidizing agents and other solutions before class. Arrange to bring items such as grape juice and flower petals to class on the day of the lab.

SAFETY The oxidizing agents in this lab pose a slight contact hazard and should be handled carefully. Safety goggles should be worn at all times. Students should also be careful to avoid splashing and spilling because the oxidizing solutions can bleach or destroy clothing; lab coats are recommended.

EXPECTED OUTCOME Various color changes occur.

ANALYZE AND CONCLUDE

1. Grids contain student observations.
2. Rankings depend on observations.
3. Color changes occur.

FOR ENRICHMENT Have students extend this lab by bringing in stained or old clothing from home. Have them test the effect of the oxidizing agents on these materials.

CHEMISTRY & YOU Fireworks are probably one of the most spectacular demonstrations of oxidation-reduction reactions that students will encounter in their daily lives. Have students look at the different colors produced by the fireworks display in the photo. Point out that the differences in the display show that different elements were involved in the chemical reactions that produced the explosions. Encourage students to describe fireworks displays they have seen. Emphasize that each of these displays depended on redox reactions.

Explain

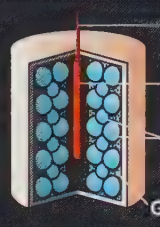
APPLY CONCEPTS Explain that a fireworks display might include the reaction of potassium nitrate (KNO_3) and sulfur (S) to produce sodium potassium oxide (K_2O), nitrogen gas (N_2), and sodium dioxide (SO_2). Have students write an equation for this reaction, and then use oxidation numbers to balance it. *($4KNO_3 + 5S \rightarrow 2K_2O + 2N_2 + 5SO_2$)* **Ask** What is the oxidizing agent in this reaction? *(potassium nitrate)* **Ask** What is the reducing agent? *(sulfur)*

Answers

1. yes; the chlorine ion in KCl is oxidized and O_2 is reduced
2. $2Mg + O_2 \rightarrow 2MgO$

CHEMISTRY & YOU: TECHNOLOGY

Fireworks



It's New Year's Eve, and at the stroke of midnight, a dazzling array of fireworks begins bursting overhead. The sights and sounds of each explosion are the result of several oxidation-reduction reactions taking place within the firework as it ascends into the sky.

There are four basic components in any firework: oxidizers, reducing agents, colorants, and binders. Oxidizers, such as nitrates, chlorates, and perchlorates, produce the oxygen needed to let the firework burn. The reducing agents, usually sulfur and carbon, combine with the oxygen to produce the heat energy for the explosion. Metal ions, such as lithium, calcium, and sodium, create the bright colors you see. And the binders hold the materials together.

These four materials are formed into small lumps known as stars. The stars are placed in a cardboard or paper shell along with gunpowder (also called black powder) and two charges. When the first charge is lit, the gunpowder propels the firework into the air. Then the second charge causes additional gunpowder to propel the stars into the sky and ignite the oxidizers, which react with the reducing agents, causing the stars to explode in brilliant flashes of color.

RED, WHITE, AND BLUE Different metal salts and compounds are used to create the different colors in fireworks. Lithium and strontium are used for red, magnesium and aluminum are used for white, and copper is used for blue.

FIREWORK ANATOMY Aerial fireworks contain stars and gunpowder within a cardboard shell. The charge and fuse are used to ignite the firework. The arrangement of the stars determines the shape of the burst, while the size and shape of the star determine the size, shape, and speed of the burst.

Take It Further

1. Identify Potassium nitrate (KNO_3) was originally used in fireworks and gunpowder. The reaction for the production of KNO_3 is

$$4KCl + 4HNO_3 + O_2 \longrightarrow 4KNO_3 + 2Cl_2 + 2H_2O$$

Is this a redox reaction? If so, which substance is oxidized and which is reduced?

2. Describe The bright white light of some fireworks is produced when magnesium reacts with oxygen in the air to form magnesium oxide. Write a balanced equation for this reaction.

21st Century Learning To be successful in the 21st century, students need skills and learning experiences that extend beyond subject matter mastery. The following project helps students build the following 21st Century Skills: *Creativity and Innovation; Critial Thinking and Problem Solving; Communication and Collaboration; Information Literacy; Media Literacy; Information, Communications and Technology Literacy; Initiative and Self-Direction; Productivity and Accountability.*

FIREWORKS CHEMISTRY Pose the following challenge to your students. *Suppose you work for a fireworks company, and it is your job to choose the oxidizing and reducing chemicals to use for one of their fireworks. What will you use?*

- Research various chemicals used to produce colors in fireworks.
- Choose one color, and produce a creative computer display that includes the redox reaction as a balanced equation.
- Identify the color of the fireworks produced, the oxidizing agent, and the reducing agent.

20.2 Oxidation Numbers

C.4.6 Redox reactions

CHEMISTRY & YOU

Q: *Why does a sparkler have such a bright light?* If you have ever seen or held a sparkler, then you know that sparklers give off very bright light. They are like handheld fireworks. Sparklers contain powdered metals. As the sparklers burn, a chemical reaction changes the metals. In this lesson, you will learn about how oxidation and reduction in reactions like these are defined in terms of a change in oxidation number.

Key Questions

What is the general rule for assigning oxidation numbers?

How are oxidation and reduction defined in terms of a change in oxidation number?

Vocabulary

- oxidation number

Assigning Oxidation Numbers

What is the general rule for assigning oxidation numbers?

An **oxidation number** is a positive or negative number assigned to an atom to indicate its degree of oxidation or reduction. **As a general rule, a bonded atom's oxidation number is the charge that it would have if the electrons in the bond were assigned to the atom of the more electronegative element.** In the next lesson, you will learn that equations of complex redox reactions can be balanced by the use of oxidation-number changes. The set of rules on the next page should help you determine oxidation numbers.

In binary ionic compounds, such as NaCl and $CaCl_2$, the oxidation numbers of the atoms equal their ionic charges (Rule 1). The compound sodium chloride is composed of sodium ions (Na^{1+}) and chloride ions (Cl^{1-}). Thus the oxidation number of sodium is +1, and that of chlorine is −1. In $CaCl_2$, the oxidation number of calcium is +2, and that of chlorine is −1. Notice that the sign is put before the oxidation number.

Because water is a molecular compound, no ionic charges are associated with its atoms. However, oxygen is reduced in the formation of water. Oxygen is more electronegative than hydrogen. So, in water, the two shared electrons in the H—O bond are shifted toward oxygen and away from hydrogen. Picture the electrons contributed by the two hydrogen atoms as being completely transferred to the oxygen. The charges that would result from this transfer are the oxidation numbers of the bonded elements. The oxidation number of oxygen is −2, and the oxidation number of each hydrogen is +1 (Rules 2 and 3). Oxidation numbers are often written above the chemical symbols in a formula. For example, water can be represented as

$$\overset{+1\ -2}{H_2O}$$

Focus on ELL

1 CONTENT AND LANGUAGE Direct students' attention to the chart called Rules for Assigning Oxidation Numbers, on the following page. Guide students in creating a visual aid using colors, symbols, and examples of the rules. Allow them to refer to this visual throughout the chapter.

2 FRONTLOAD THE LESSON Review the concepts of oxidation and reduction by asking students to explain how each process affects an atom's oxidation number. Then, write a sample reaction on the board. Ask students to write an oxidation reaction and a reduction reaction to help them identify the oxidizing and reducing agents in the reaction.

3 COMPREHENSIBLE INPUT Prepare a two-column chart of the rules for assigning oxidation numbers. Write a simplified form of each rule in the first column, and place examples in the second column. When discussing the sample problems, identify any polyatomic ions, and make sure that students understand the charge distribution within them before proceeding with the solutions.

Key Objectives

20.2.1 STATE the general rule for assigning oxidation numbers.

20.2.2 DEFINE oxidation and reduction in terms of a change in oxidation number.

Additional Resources

Reading and Study Workbook, Lesson 20.2

Available Online or on Digital Media:

- Teaching Resources, Lesson 20.2

PearsonChem.com

Engage

CHEMISTRY & YOU Have students read the opening paragraph. Explain that sparklers burn when lit with a match because the reaction of metal with oxygen is a combustion reaction. **Ask** Does a metal gain or lose electrons when it reacts with oxygen? *(It loses electrons.)* Remind students that oxidation is the complete or partial loss of electrons or gain of oxygen.

Activate Prior Knowledge

To prepare students for learning the rules for assigning oxidation numbers, have them define and provide two examples of the following: monoatomic ion, metal hydride, peroxide, element, neutral compound, polyatomic ion.

Foundations for Reading

BUILD VOCABULARY Have students relate the vocabulary term, *oxidation number*, with other, similar terms used in the chapter, such as *oxidize* and *oxide*.

IN ACADEMIC STANDARDS for SCIENCE

C.4.6 Determine oxidation states and identify the substances apparently gaining and losing electrons in redox reactions.

READING STRATEGY Have students preview the lesson's content by making index cards, one for each of the six rules for assigning oxidation numbers. As they read the lesson, students should try to find an example for each rule and write it on the back of the corresponding card.

Explain

Assigning Oxidation Numbers

START A CONVERSATION Explain that determining oxidation numbers of elements in compounds is a way for chemists to keep track of electron transfer during redox reactions. Point out that oxidation numbers are an accounting system for electrons. Then review the chart called Rules for Assigning Oxidation Numbers with the class, going over many examples of each rule until students are comfortable with these numbers.

Misconception Alert

Students may tend to assign an element the same oxidation number in every compound. Explain that the same element can have several oxidation numbers, depending on the compound. **Ask** What are the oxidation numbers of iodine in HIO_4, HIO_3, HIO, I_2, and HI? *(7, 5, 1, 0, 1, respectively)*

Extend

Connect to ENVIRONMENTAL SCIENCE

Have students examine why carbon monoxide is extremely poisonous to living systems whereas carbon dioxide is relatively harmless. Have students write a paragraph using what they have learned about oxidation numbers to support their findings. *(Carbon in carbon monoxide has an oxidation number that is lower than the oxidation number for carbon in carbon dioxide. Carbon monoxide is a better reducing agent than carbon dioxide.)*

Explore

Class Activity

PURPOSE Students will work cooperatively to assign oxidation numbers to various elements.

PROCEDURE Write formulas for ionic and molecular compounds on the board. Divide the class into groups of two and have students work together to assign oxidation numbers to all of the elements in each compound. Students can use the problem-solving strategy outlined in Sample Problem 20.2.

Many elements can have several different oxidation numbers. Use rules 5 and 6 to determine the oxidation number of atoms of these elements, plus other elements not covered in the first four rules. All the substances shown in Figure 20.8 contain chromium, but chromium has a different oxidation number in its uncombined state and in each compound.

Rules for Assigning Oxidation Numbers

1. The oxidation number of a monatomic ion is equal in magnitude and sign to its ionic charge. For example, the oxidation number of the bromide ion (Br^{1-}) is -1; that of the Fe^{3+} ion is $+3$.
2. The oxidation number of hydrogen in a compound is $+1$, except in metal hydrides, such as NaH, where it is -1.
3. The oxidation number of oxygen in a compound is -2, except in peroxides, such as H_2O_2, where it is -1, and in compounds with the more electronegative fluorine, where it is positive.
4. The oxidation number of an atom in uncombined (elemental) form is 0. For example, the oxidation number of the potassium atoms in potassium metal (K) or of the nitrogen atoms in nitrogen gas (N_2) is 0.
5. For any neutral compound, the sum of the oxidation numbers of the atoms in the compound must equal 0.
6. For a polyatomic ion, the sum of the oxidation numbers must equal the ionic charge of the ion.

Figure 20.8
Chromium in its uncombined state is a dull silvery color. Orange potassium dichromate ($K_2Cr_2O_7$) and purple chromium(III) potassium sulfate ($CrK(SO_4)_2{\cdot}12H_2O$) are both compounds of chromium.
Infer ***What is the oxidation number of chromium in each compound?***

Differentiated Instruction

L3 ADVANCED STUDENTS Tell students that a breath analyzer is used to estimate the level of alcohol in a person's bloodstream. The chemical potassium dichromate is used in this process. Ask students to research the color change and the change in oxidation number of chromium if any ethanol is present in a person's breath when breathing into the apparatus. *(The Cr^{6+} in the potassium dichromate (orange) is reduced to one of its lower states, such as Cr^{3+} (green). The color change can be related to the amount of alcohol in the bloodstream.)*

ELL ENGLISH LANGUAGE LEARNERS Students may have difficulty distinguishing the word *assign* from the word *sign* when spoken. Write the word *assign* on the board and pronounce it slowly, being sure to clearly enunciate the first syllable. To avoid confusion, be sure to use the term *mathematical sign* instead of *sign* when referring to the charge on an oxidation number.

Sample Problem 20.2

Assigning Oxidation Numbers to Atoms

What is the oxidation number of each kind of atom in the following ions and compounds?

a. SO_2 **c.** Na_2SO_4
b. CO_3^{2-} **d.** $(NH_4)_2S$

1 Analyze **Identify the relevant concepts.** Use the set of rules you just learned to assign and calculate oxidation numbers.

2 Solve **Apply concepts to this situation.**

a. There are two oxygen atoms, and the oxidation number of each oxygen is −2 (Rule 3). The sum of the oxidation numbers for the neutral compound must be 0 (Rule 5). Therefore, the oxidation number of sulfur is +4, because $+4 + (2 \times (-2)) = 0$.

+4 −2
SO_2

b. The oxidation number of oxygen is −2 (Rule 3).

The sum of the oxidation numbers of the carbon and oxygen atoms must equal the ionic charge, −2 (Rule 6). The oxidation number of carbon must be +4, because $+4 + (3 \times (-2)) = -2$.

? −2
CO_3^{2-}

+4 −2
CO_3^{2-}

c. The oxidation number of each sodium ion, Na^+, is the same as its ionic charge, +1 (Rule 1). The oxidation number of oxygen is −2 (Rule 3).

+1 ? −2
Na_2SO_4

For the sum of the oxidation numbers in the compound to be 0 (Rule 5), the oxidation number of sulfur must be +6, because $(2 \times (+1)) + (+6) + (4 \times (-2)) = 0$.

+1 +6 −2
Na_2SO_4

d. Ammonium ions, NH_4^+, have an ionic charge of +1, so the sum of the oxidation numbers of the atoms in the ammonium ion must be +1. The oxidation number of hydrogen is +1 in this ion. So, the oxidation number of nitrogen must be −3.

? +1
NH_4^+
$? + 4(+1) = +1$
$-3 + 4(+1) = +1$

Two ammonium ions have a total charge of +2. Since the compound $(NH_4)_2S$ is neutral, sulfur must have a balancing oxidation number of −2.

−3 +1 −2
$(NH_4)_2S$

3 Evaluate **Do the results make sense?** The results are consistent with the rules for determining oxidation numbers. Also, addition of the oxidation numbers correctly gives the final overall charge for the ion and the three neutral compounds.

10. Determine the oxidation number of each element in the following:
a. S_2O_3 **c.** P_2O_5
b. Na_2O_2 **d.** NO_3^-

11. Determine the oxidation number of chlorine in each of the following substances:
a. $KClO_3$ **c.** $Ca(ClO_4)_2$
b. Cl_2 **d.** Cl_2O

Foundations for Math

WRITING EQUATIONS Show students that they can set up and solve an equation to assign an oxidation number to an ion or a compound.

In **Sample Problem 20.2c,** use an equation to find the oxidation number for Na_2SO_4. Let x equal the oxidation number for sulfur; set the sum of the charges equal to zero since the compound is neutral.

Follow the order of operations and use an inverse operation to isolate x.

$(+1)(2) + x + (-2)(4) = 0$ Sum of the charges = 0.
$2 + x - 8 = 0$ Multiply from left to right.
$x - 6 = 0$ Add.
$x = 6$ Add −6 to both sides.

The charge on sulfur is +6.

Sample Practice Problem

Determine the oxidation number for the carbon atom in each of the following compounds:

CH_4, CH_3OH, H_2CO

(CH_4 (−4); CH_3OH (−2); H_2CO (0))

Explore

Teacher Demo

PURPOSE Students will observe a redox reaction and write a balanced equation describing it.

MATERIALS 100 mL of 0.1*M* lead(II) acetate [$Pb(CH_3COO)_2$], 150-mL beaker, 1-cm × 3-cm zinc strip, sodium sulfide, 3*M* NaOH, 1*M* iron(III) chloride, stirring rod, plastic container

SAFETY Lead(II) acetate is a suspected carcinogen and mutagen. Perform the activity in a well-ventilated area. Wear safety an goggles, an apron, and disposable gloves.

PROCEDURE Pour 100 mL of 0.1*M* lead(II) acetate [$Pb(CH_3COO)_2$] into a 150-mL beaker and add a 1-cm × 3-cm zinc strip.

EXPECTED OUTCOME A "tree" of lead will form over the course of a day. Ask students to write a balanced equation for the redox reaction that occurred. Have them assign oxidation numbers for Zn and Pb. Based on changes in oxidation number, have students identify the elements that were oxidized and reduced.

ANSWERS $Zn(s) + Pb(CH_3COO)_2\,(aq) \rightarrow Pb(s) + Zn\,(CH_3COO)_2\,(aq)$

Reactants: Zn^0, Pb^{2+}; Products: Zn^{2+}, Pb^0
Zn was oxidized. Pb was reduced.

DISPOSAL Dispose of the reaction mixture by adding a threefold molar excess of sodium sulfide to the contents of the beaker and stirring occasionally for one hour. Adjust the pH to neutral with 3*M* NaOH. Filter or decant the mixture. Allow the residue to dry. Add a threefold excess of 1*M* iron(III) chloride to the filtrate, stirring slowly. Allow the precipitate to settle, and then filter or decant. Put the dry precipitate and filtered residue in a plastic container and bury the container at an approved landfill site. Flush the neutral filtrate down the drain with excess water.

Oxidation-Number Changes in Chemical Reactions

CHEMISTRY & YOU The oxidation numbers of the metals change.

USE VISUALS Have students examine Figure 20.10. **Ask** What would happen if a copper nail were added to a solution of iron(II) sulfate instead? Explain. *(Nothing would happen because copper is below iron in the activity series of metals.)*

CHEMISTRY & YOU

Q: *What happens to the oxidation numbers of metals as they burn in a sparkler?*

Oxidation-Number Changes in Chemical Reactions

How are oxidation and reduction defined in terms of a change in oxidation number?

Figure 20.9 shows what happens when copper wire is placed in a solution of silver nitrate. In this reaction, the oxidation number of silver decreases from +1 to 0 as each silver ion (Ag^{1+}) gains an electron and is reduced to silver metal (Ag^0). Copper's oxidation number increases from 0 to +2 as each atom of copper metal (Cu^0) loses two electrons and is oxidized to a copper(II) ion (Cu^{2+}). Here is the equation with oxidation numbers added:

$$\overset{+1\ +5-2}{2AgNO_3(aq)} + \overset{0}{Cu(s)} \longrightarrow \overset{+2\ +5-2}{Cu(NO_3)_2(aq)} + \overset{0}{2Ag(s)}$$

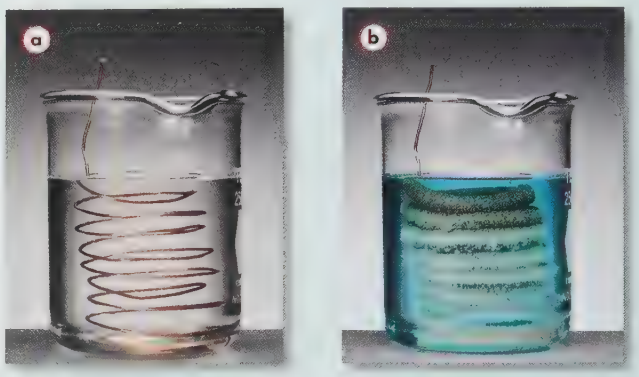

Figure 20.9
Oxidation of Copper
Copper reacts with silver nitrate. **a.** A copper wire is placed in a silver nitrate solution. **b.** Crystals of silver coat the wire, and the solution slowly turns blue as a result of the formation of copper(II) nitrate.
Draw Conclusions *What change occurs in the oxidation number of silver? How does the oxidation number of copper change?*

Figure 20.10 illustrates a redox reaction that shows what occurs when a shiny iron nail is dipped into a solution of copper(II) sulfate.

You can define oxidation and reduction in terms of a change in oxidation number. **An increase in the oxidation number of an atom or ion indicates oxidation. A decrease in the oxidation number of an atom or ion indicates reduction.**

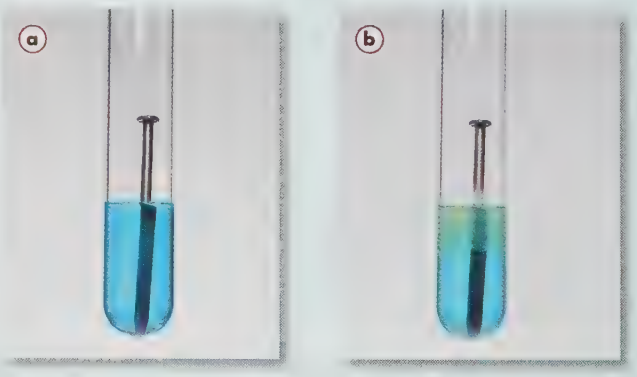

Figure 20.10
Reduction of Copper
A redox reaction occurs between iron and copper. **a.** An iron nail is placed in a copper(II) sulfate solution. **b.** The iron reduces Cu^{2+} ions in solution and is simultaneously oxidized to Fe^{2+}. The iron becomes coated with metallic copper.

UbD Check for Understanding

How are oxidation and reduction defined in terms of a change in oxidation number?

Assess students' understanding of this concept by having them write a balanced equation for the reaction shown in Figure 20.10 and assign an oxidation number to each atom or ion. Have them then show mathematically the changes in oxidation number that indicate reduction and oxidation. *[$Fe(s) + CuSO_4(aq) \rightarrow Cu(s) + FeSO_4(aq)$; Fe: 0, $CuSO_4$: +2,+6, −2,Cu: 0, $FeSO_4$: +2,+6, −2; Fe: 0 to +2 (oxidation), Cu: +2 to 0 (reduction)]*

Ask students to write a one-minute answer to this question, using the reaction between $AgNO_3$ and Cu (above) as an example.

ADJUST INSTRUCTION If students are having difficulty answering this question, have them reread the first paragraph on this page and the bold text following the key icon in the last paragraph. Then walk them through the process of answering the question.

SampleProblem 20.3

Identifying Oxidized and Reduced Atoms

Use changes in oxidation number to identify which atoms are oxidized and which are reduced in the following reactions. Also identify the oxidizing agent and the reducing agent.

a. $Cl_2(g) + 2HBr(aq) \longrightarrow 2HCl(aq) + Br_2(l)$

b. $C(s) + O_2(g) \longrightarrow CO_2(g)$

1 Analyze **Identify the relevant concepts.** An increase in oxidation number indicates oxidation. A decrease in oxidation number indicates reduction. The substance that is oxidized in a redox reaction is the reducing agent. The substance that is reduced is the oxidizing agent.

2 Solve **Apply concepts to this situation.**

a. Use the rules to assign oxidation numbers to each atom in the equation.

Then, use the changes in oxidation numbers to identify which atoms are oxidized and which are reduced.

Finally, identify the oxidizing and reducing agent.

$$\overset{0}{Cl_2}(g) + 2\overset{+1-1}{HBr}(aq) \longrightarrow 2\overset{+1-1}{HCl}(aq) + \overset{0}{Br_2}(l)$$

The element chlorine is reduced because its oxidation number decreases (0 to −1). The bromide ion from HBr(*aq*) is oxidized because its oxidation number increases (−1 to 0). Chlorine is reduced, so Cl_2 is the oxidizing agent. The bromide ion from HBr(*aq*) is oxidized, so Br^- is the reducing agent.

b. Use the rules to assign oxidation numbers to each atom in the equation.

Then, use the changes in oxidation numbers to identify which atoms are oxidized and which are reduced.

Finally, identify the oxidizing agent and reducing agent.

$$\overset{0}{C}(s) + \overset{0}{O_2}(g) \longrightarrow \overset{+4-2}{CO_2}(g)$$

The element carbon is oxidized because its oxidation number increases (0 to +4). The element oxygen in reduced because its oxidation decreases (0 to −2). Carbon is oxidized, so C is the reducing agent. Oxygen is reduced, so O_2 is the oxidizing agent.

3 Evaluate **Do the results make sense?** It makes sense that what is oxidized in a chemical reaction is the reducing agent because it loses electrons—it becomes the agent by which the atom that is reduced gains electrons. Conversely, it makes sense that what is reduced in a chemical reaction is the oxidizing agent because it gains electrons—it is the agent by which the atom that is oxidized loses electrons.

12. Use the changes in oxidation numbers to identify which atoms are oxidized and which are reduced in each reaction.

a. $2H_2(g) + O_2(g) \longrightarrow 2H_2O(l)$

b. $2KNO_3(s) \longrightarrow 2KNO_2(s) + O_2(g)$

13. Identify the oxidizing agent and the reducing agent in each equation in Problem 12.

Foundations for Math

COMPARING INTEGERS Explain that the charges of the atoms are integer values. To determine which atoms in a redox equation are oxidized and which are reduced, students need to simply compare integers.

In **Sample Problem 20.3a** have students use the symbols >, <, and = to compare the charges in the order in which they appear in the reaction.

For chlorine: 0 > −1

The charge goes from a greater value to a lesser value, so chlorine is reduced.

For hydrogen: +1 = +1

The charges are equal, so hydrogen is neither oxidized nor reduced.

For bromine: −1 < 0

The charge goes from a lesser value to a greater value, so bromine is oxidized.

For struggling students, use an integer number line to plot and compare the values.

Explain

Sample Practice Problem

For the following equation, identify which atoms are oxidized and which atoms are reduced. Then identify the oxidizing and reducing agents.

$$2HgO \rightarrow O_2 + 2Hg$$

(Mercury is reduced; it is the oxidizing agent. Oxygen is oxidized; it is the reducing agent.)

Explore

Class Activity

PURPOSE Students will identify and write equations for redox reactions.

MATERIALS 3 small glass test tubes, zinc, copper, magnesium, 0.1*M* HCl, medicine dropper or pipet

PROCEDURE Have students work in pairs. Give each pair a set of three small glass test tubes containing a small portion of zinc, copper, and magnesium. Have students add approximately 10 drops of 0.1*M* HCl to the metals and note signs of reaction. They should see bubbles form in the tubes containing zinc and magnesium but not in the tube containing copper. **Ask** Can you guess the identity of the gas in the tubes containing zinc and magnesium? *(H_2(g))* Have students write equations for the reactions of zinc and magnesium with HCl. Have students explain why these reactions are redox reactions.

Answers

FIGURE 20.9 The oxidation number of silver changes from +1 to 0; the oxidation number of copper changes from 0 to +2.

12. **a.** H_2 oxidized, O_2 reduced

b. N reduced, O oxidized

13. **a.** H_2 reducing agent, O_2 oxidizing agent

b. N oxidizing agent, O reducing agent

Explain

Sample Practice Problem

For the following equation, identify which atoms are oxidized and which atoms are reduced. Then identify the oxidizing and reducing agents.

$$2B_2O_3(s) + 6Cl_2(g) \rightarrow 4BCl_3(l) + 3O_2(g)$$

(Chlorine is reduced; it is the oxidizing agent. Oxygen is oxidized; it is the reducing agent.)

Evaluate

Informal Assessment

To assess students' understanding of oxidation numbers, ask students to determine the oxidation numbers for the following compounds: KNO_3 *(K +1, N +5, O –2)*; Na_2SO_3 *(Na +1, S +4, O –2)*; P_2O_5 *(P +5, O –2)*; MgH_2 *(Mg +2, H –1)*; ClF_3 *(Cl +3, F –1)*; HIO *(H +1, I +1, O –2)*. **Ask** What do the sign and magnitude of the oxidation number of an element in a compound indicate? *(The sign indicates loss (+) or gain (–) of electrons compared to the isolated element; the magnitude indicates the degree of the gain or loss.)* **Ask** If fluorine is converted to F^- from F_2, what is the change in oxidation number? Is this oxidation or reduction? *(Change is 0 to –1; reduction.)* Then have students complete the 20.2 Lesson Check.

Reteach

Stress that oxidation numbers refer to the combining capacity of single atoms. Thus, a change in oxidation number must be calculated on a per-atom basis. Review the rules for assigning oxidation numbers and use examples such as Mn_2O_3 and $Cr_2O_7^{2}$ to explain to students that they must consider the number of atoms involved. Then have students repeat using a different pair of compounds than before.

Answers

14. **a.** N in NH_4^+ is oxidized (–3 to 0); H is unchanged; N in NO_2^- is reduced (+3 to 0); O is unchanged.
b. Pb is reduced (+4 to +2); O is unchanged; H is unchanged; I is oxidized (–1 in HI to 0 in I_2).

15. **a.** N in NH_4^+ is the reducing agent; N in NO_2^- is the oxidizing agent.
b. Pb is the oxidizing agent; I is the reducing agent.

FIGURE 20.11 The oxidation number of potassium changes from 0 to +1, so this is a redox reaction. The oxidation number of zinc changes from 0 to +2, so this is a redox reaction.

Sample Problem 20.4

Identifying Oxidized and Reduced Atoms

Use changes in oxidation number to identify which atoms are oxidized and which are reduced in the following reactions. Also identify the oxidizing agent and the reducing agent.

$$Zn(s) + 2MnO_2(s) + 2NH_4Cl(aq) \longrightarrow ZnCl_2(aq) + Mn_2O_3(s) + 2NH_3(g) + H_2O(l)$$

1 Analyze **Identify the relevant concepts.**

2 Solve **Apply concepts to this situation.**

Use the rules to assign oxidation numbers to each atom in the equation.

$$\overset{0}{Zn(s)} + \overset{+4\,-2}{2MnO_2(s)} \; \overset{-3+1\,-1}{2NH_4Cl(aq)} \longrightarrow \overset{+2\,-1}{ZnCl_2(aq)} + \overset{+3\,-2}{Mn_2O_3(s)} + \overset{-3+1}{2NH_3(g)} + \overset{+1-2}{H_2O(l)}$$

Then, use the changes in oxidation numbers to identify which atoms are oxidized and which are reduced.

The element zinc is oxidized because its oxidation number increases (0 to +2).
The manganese ion is reduced because its oxidation number decreases (+4 to +3).

Finally, identify the oxidizing and reducing agent.

Zinc is oxidized, so Zn is the reducing agent.
Manganese (in MnO_2) is reduced, so Mn^{4+} is the oxidizing agent.

14. Identify which atoms are oxidized and which are reduced in each reaction.
a. $NH_4NO_2(s) \longrightarrow N_2(g) + 2H_2O(g)$
b. $PbO_2(aq) + 4HI(aq) \longrightarrow I_2(aq) + PbI_2(s) + 2H_2O(l)$

15. Identify the oxidizing agent and the reducing agent in each equation in Problem 14.

20.2 LessonCheck

16. **Explain** What is the general rule for assigning oxidation numbers?

17. **Explain** How is a change in oxidation number related to the process of oxidation and reduction?

18. **Explain** How is charge used to assign oxidation numbers to the elements in a polyatomic ion?

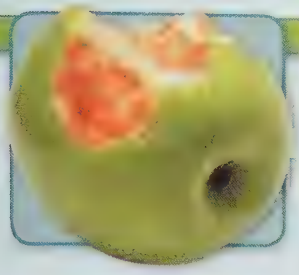
19. **Identify** Use the changes in oxidation numbers to identify which atoms are oxidized and which are reduced in each reaction.
a. $2Na(s) + Cl_2(g) \longrightarrow 2NaCl(s)$
b. $2HNO_3(aq) + 6HI(aq) \longrightarrow 2NO(g) + 3I_2(s) + 4H_2O(l)$
c. $3H_2S(g) + 2HNO_3(aq) \longrightarrow 3S(s) + 2NO(g) + 4H_2O(l)$
d. $2PbSO_4(s) + 2H_2O(l) \longrightarrow Pb(s) + PbO_2(s) + 2H_2SO_4(aq)$

20. **Identify** Identify the oxidizing agent and the reducing agent in each reaction in Problem 19.

Lesson Check Answers

16. The oxidation number is the charge a bonded atom would have if the electrons in the bond were assigned to the more electronegative element.

17. An increase in oxidation number indicates oxidation; a decrease in oxidation number indicates reduction.



18. For a polyatomic ion, the sum of the oxidation numbers must equal the ionic charge of the ion.

19. **a.** Na, oxidized; Cl_2, reduced
b. I, oxidized; N, reduced
c. S, oxidized; N, reduced
d. Pb, oxidized and reduced

20. **a.** Na reducing agent, Cl_2 oxidizing agent
b. N in HNO_3 oxidizing agent, I in HI reducing agent
c. N in HNO_3, oxidizing agent; S in H_2S, reducing agent
d. Pb in $PbSO_4$, oxidizing-reducing agent

20.3 Describing Redox Equations

C.4.6 Redox reactions

CHEMISTRY & YOU

Q: *Why does cut fruit turn brown?* If you have eaten an apple, then you have probably noticed that the flesh of the apple turns brown after you remove the skin. The apple is still safe to eat; it just doesn't look as appetizing. As you may have guessed, the browning is a chemical reaction. In this lesson, you will learn more about identifying certain types of chemical reactions and how to write and balance chemical equations for redox reactions.

Key Questions

- *What are the two classes of chemical reactions?*
- *What are two different methods for balancing a redox equation?*

Vocabulary

- oxidation-number-change method
- half-reaction
- half-reaction method

Identifying Redox Reactions

What are the two classes of chemical reactions?

In general, all chemical reactions can be assigned to one of two classes. **One class of chemical reactions is oxidation-reduction (redox) reactions, in which electrons are transferred from one reacting species to another. The other class includes all other reactions, in which no electron transfer occurs.** Many single-replacement reactions, combination reactions, decomposition reactions, and combustion reactions are redox reactions. Two examples of redox reactions are shown in Figure 20.11. Figure 20.11a shows what happens when potassium metal reacts with water. Figure 20.11b shows the reaction of zinc with hydrochloric acid. Examples of reactions that are not redox reactions include double-replacement reactions and acid-base reactions.

Figure 20.11 Single-Replacement Redox Reactions
Single-replacement reactions are redox reactions. **a.** Potassium metal reacts violently with water to produce hydrogen gas (which ignites) and potassium hydroxide. **b.** Zinc metal reacts vigorously with hydrochloric acid to produce hydrogen gas and zinc chloride.
Apply Concepts *Explain why each reaction is a redox reaction.*

Focus on ELL

1 CONTENT AND LANGUAGE Direct students' attention to the Key Questions. Read each question aloud. Write the words *classes*, *balance*, and *procedure* on the board. Have students use a dictionary to look up the various uses of these words. Ask students to retell, in their own words, what the questions are asking before they begin reading.

2 FRONTLOAD THE LESSON Review the process of assigning oxidation numbers and have students practice determining oxidation numbers for various polyatomic ions. Then review the concept of ionic equations and have students practice writing complete and net ionic equations in preparation for balancing redox reactions by using the half-reaction method.

3 COMPREHENSIBLE INPUT Create large visuals to display the steps to follow for using oxidation-number changes and for using the half-reaction method to balance redox equations. Simplify the steps and use symbols below words when appropriate.

LESSON 20.3

Key Objectives

20.3.1 IDENTIFY the two classes of chemical reactions.

20.3.2 BALANCE a redox equation by using the oxidation-number-change method.

20.3.3 BALANCE a redox equation using half-reactions.

Additional Resources

Reading and Study Workbook, Lesson 20.3

PearsonChem.com

Engage

CHEMISTRY & YOU Direct students to look at the photograph of the apple and to read the corresponding text. Explain that the chemicals involved in the browning of fruit are called phenols. **Ask** Do you think the phenols in the apple are oxidized or reduced during the browning process? Why? *(The chemicals are oxidized because they are reacting with oxygen.)*

Activate Prior Knowledge

Ask students to recall the types of chemical reactions they studied in previous chapters. Write an example of each kind of equation on the board or overhead projector. Ask students to predict which equations represent redox reactions.

IN ACADEMIC STANDARDS for SCIENCE

C.4.6 Determine oxidation states and identify the substances apparently gaining and losing electrons in redox reactions.

Foundations for Reading

BUILD VOCABULARY Explain the meaning of the new terms by using examples. Then have students create a short summary in their own words to convey their understanding of each term.

READING STRATEGY Tell students to consider previous concepts, such as the law of conservation of mass, when reading about balancing redox equations.

Explain

Identifying Redox Reactions

APPLY CONCEPTS Remind students of the concepts that underlie the need to balance chemical equations. Explain that for all equations, mass must be conserved by balancing the number of atoms and electrical neutrality must be maintained by balancing charges. **Ask** How does the statement *Electrons cannot be created or destroyed* relate to the balancing of redox reactions? *(The balancing of redox reactions must also reflect the electrons gained and lost by oxidizing and reducing agents.)*

USE AN ANALOGY To convey the concepts involved with balancing chemical equations, use an analogy of a checking account. Explain that to maintain sufficient funds to cover checks written, money withdrawn eventually needs to be balanced by deposits.

CHEMISTRY & YOU A redox reaction is occurring on the surface of the fruit.

Figure 20.12 Redox in Lightning When lightning bolts heat the air to extreme temperatures, the redox reaction that takes place between nitrogen and oxygen forms nitrogen monoxide.

During an electrical storm, as shown in Figure 20.12, oxygen molecules and nitrogen molecules in the air react to form nitrogen monoxide. This reaction is an example of a combination reaction. The equation for the reaction is shown below.

$$N_2(g) + O_2(g) \longrightarrow 2NO(g)$$

How can you tell if this is a redox reaction? If the oxidation number of an element in a reacting species changes, then that element has undergone either oxidation or reduction. Therefore, the reaction as a whole must be a redox reaction. In the example above, the oxidation number of nitrogen increases from 0 to +2, while the oxidation number of oxygen decreases from 0 to −2. Therefore, the reaction between nitrogen and oxygen to form nitrogen monoxide is a redox reaction.

Many reactions in which color changes occur are redox reactions. One example is the apple on the first page of this lesson. Another example is shown in Figure 20.13. Written in ionic form, the unbalanced equation for this reaction is

$$\underset{\text{Permanganate ion (purple)}}{MnO_4^-(aq)} + \underset{\text{Bromide ion (colorless)}}{Br^-(aq)} \longrightarrow \underset{\text{Manganese(II) ion (colorless)}}{Mn^{2+}(aq)} + \underset{\text{Bromine (brown)}}{Br_2(aq)}$$

CHEMISTRY & YOU

Q: *Some fruits, including apples, turn brown when you cut them. What do you think is happening on the surface of the fruit that causes it to turn brown?*

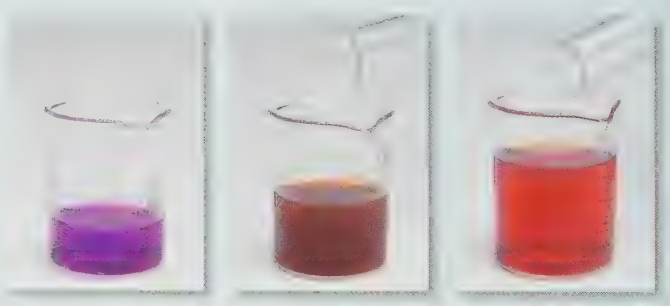

Figure 20.13 Color Clues A color change can signal a redox reaction. When a colorless solution containing bromide ions (Br^-) is added to a solution containing permanganate ions (MnO_4^-), the distinctive purple color of the permanganate ion is replaced by the pale brown color of bromine.

Differentiated Instruction

LPR LESS PROFICIENT READERS Have students create a two-column table with labels for the two classes of chemical reactions as the column headings. As you discuss a particular reaction, have students note the reaction in the appropriate column.

L3 STRUGGLING STUDENTS Use a lab balance scale and colored blocks to visually demonstrate whether a reaction is a redox reaction. Use a specific color of block for each element in the reaction, determine the charge for each element or compound, and place the number of corresponding blocks on the reactant and the product sides of the balance. Have students observe the balance to determine whether or not it is an example of a redox reaction.

708 Chapter 20 • Lesson 3

Sample Problem 20.5

Identifying Redox Reactions

Use the change in oxidation number to identify whether each reaction is a redox reaction or a reaction of some other type. If a reaction is a redox reaction, identify the element reduced, the element oxidized, the reducing agent, and the oxidizing agent.

a. $Cl_2(g) + 2NaBr(aq) \longrightarrow 2NaCl(aq) + Br_2(aq)$

b. $2NaOH(aq) + H_2SO_4(aq) \longrightarrow Na_2SO_4(aq) + 2H_2O(l)$

1 Analyze **Identify the relevant concepts.**

If changes in oxidation number occur, the reaction is a redox reaction. The element whose oxidation number increases is oxidized and is the reducing agent. The element whose oxidation number decreases is reduced and is the oxidizing agent.

2 Solve **Apply concepts to this situation.**

a. Assign oxidation numbers.

Interpret the change (or lack of change) in oxidation numbers to identify if the reaction is a redox reaction.

$$\overset{0}{Cl_2(g)} + \overset{+1\ -1}{2NaBr(aq)} \longrightarrow \overset{+1\ -1}{2NaCl(aq)} + \overset{0}{Br_2(aq)}$$

This is a redox reaction. The chlorine is reduced. The bromide ion is oxidized. Chlorine is the oxidizing agent; the bromide ion is the reducing agent.

b. Assign oxidation numbers.

Interpret the change (or lack of change) in oxidation numbers to identify if the reaction is a redox reaction.

$$\overset{+1-2+1}{2NaOH(aq)} + \overset{+1+6-2}{H_2SO_4(aq)} \longrightarrow \overset{+1+6-2}{Na_2SO_4(aq)} + \overset{+1-2}{2H_2O(l)}$$

None of the elements change in oxidation number. This is not a redox reaction.

This is an acid-base (neutralization) reaction.

21. Identify which of the following are redox reactions. If a reaction is a redox reaction, name the element oxidized and the element reduced.

a. $Mg(s) + Br_2(l) \longrightarrow MgBr_2(s)$

b. $H_2CO_3(aq) \longrightarrow H_2O(l) + CO_2(g)$

22. Identify which of the following are oxidation-reduction reactions. If a reaction is a redox reaction, name the element oxidized and the element reduced.

a. $CaCO_3(s) + 2HCl(aq) \longrightarrow CaCl_2(aq) + H_2O(l) + CO_2(g)$

b. $CuO(s) + H_2(g) \longrightarrow Cu(s) + H_2O(l)$

Balancing Redox Equations

What are two different methods for balancing a redox equation?

Many oxidation-reduction reactions are too complex to be balanced by trial and error. Fortunately, two systematic methods are available. **Two different methods for balancing redox equations are the oxidation-number-change method and the half-reaction method.** These two methods are based on the fact that the total number of electrons gained in reduction must equal the total number of electrons lost in oxidation. One method uses oxidation-number changes, and the other uses half-reactions.

Foundations for Math

USE A TABLE Some students may benefit from using a table to organize the information about a reaction. Explain that a table is a good visual tool that can be helpful in keeping track of all of the elements and corresponding charges in a reaction.

In **Sample Problem 20.5a** show students how to create a table and organize the information about the reaction. Then point out how easy it is to see if the reaction is a redox reaction.

Element	Reactant Charge	Product Charge	Compare Charges		
Cl	0	−1	reduced	→	oxidizing agent
Na	1	1	neutral	→	neutral
Br	−1	0	gained	→	reducing agent

Sample Practice Problem

Have students determine if the following reaction is a redox reaction. Then have them determine which element is oxidized and which element is reduced.

$$2KMnO_4 + 3KCN + H_2O \rightarrow 2MnO_2 + 2KOH + 3K(OCN)$$

(It is a redox reaction; C is oxidized, and Mn is reduced.)

CRITICAL THINKING As a class, discuss examples in which "balancing" is required to achieve conservation. **Ask** How does the first law of thermodynamics, which states that energy must be conserved, relate to balancing? *(To conserve energy, any energy change in a system must be balanced by an equal and opposite energy change in the surroundings.)*

Answers

21. **a.** Redox reaction: Mg is oxidized, and Br_2 is reduced.

b. not a redox reaction

22. **a.** not a redox reaction

b. Redox reaction: H_2 is oxidized, and Cu is reduced.

Explore

Teacher Demo

PURPOSE Students will observe that redox reactions can sometimes be identified as a result of color changes.

MATERIALS 6 crystals of potassium permanganate ($KMnO_4$), 540 mL of water, large beaker, 1 g sodium hydrogen sulfite ($NaHSO_3$), two 50-mL beakers, 1 g barium chloride dihydrate ($BaCl_2 \cdot 2H_2O$), 3*M* H_2SO_4, stirring rod, plastic container

CAUTION Potassium permanganate is an irritant and a suspected mutagen. Barium chloride is toxic.

PROCEDURE Dissolve 6 crystals of potassium permanganate ($KMnO_4$) in 500 mL of water in a large beaker. Dissolve 1 g sodium hydrogen sulfite ($NaHSO_3$) in 20 mL of water in a 50-mL beaker. Add this solution to the $KMnO_4$ solution and stir. Dissolve 1 g barium chloride dihydrate ($BaCl_2 \cdot 2H_2O$) in 20 mL of water in another 50-mL beaker. Add this solution to the large beaker and stir.

EXPECTED OUTCOMES In the first reaction, the purple solution becomes colorless. When the $BaCl_2$ solution is added, the reaction mixture turns cloudy-white. The first reaction involves reduction of MnO_4^- to colorless Mn^{2+} and oxidation of HSO_3^- to HSO_4^-. The second reaction is not a redox reaction; it involves the formation of insoluble $BaSO_4$.

DISCUSS Ask students to use the oxidation-number-change method to balance this redox equation:

$$Cu(s) + HNO_3(aq) \rightarrow Cu(NO_3)_2(aq) + NO(g) + H_2O(l)$$

$$[3Cu(s) + 8HNO_3(aq) \rightarrow 3Cu(NO_3)_2(aq) + 2NO(g) + 4H_2O(l)]$$

DISPOSAL Dispose of the waste solution by adding 3*M* H_2SO_4 until precipitation of $BaSO_4$ appears to be complete. Let stand overnight. Filter or decant the liquid. Dry the residue, place it in a plastic container, and bury the container at an approved landfill site. Neutralize the filtrate, and flush it down the drain with excess water.

Figure 20.14
Reduction of Iron Ions
In a blast furnace like this one, air is blown through a combination of iron ore and coke. The carbon monoxide produced from the oxidation of coke reduces the Fe^{3+} ions to metallic iron.

Using Oxidation-Number Changes You can use oxidation numbers to keep track of electron transfers. In the **oxidation-number-change method,** you balance a redox equation by comparing the increases and decreases in oxidation numbers. To use this method, start with the skeleton equation for the redox reaction. As an example, look at the process used to obtain metallic iron from iron ore in a blast furnace, shown in Figure 20.14.

$$Fe_2O_3(s) + CO(g) \longrightarrow Fe(s) + CO_2(g) \text{ (unbalanced)}$$

Step 1: Assign oxidation numbers to all the atoms in the equation. Write the numbers above the atoms.

$$\overset{+3\ -2}{Fe_2O_3(s)} + \overset{+2-2}{CO(g)} \longrightarrow \overset{0}{Fe(s)} + \overset{+4-2}{CO_2(g)}$$

The oxidation number is stated per atom. So although the total positive charge of Fe ions in Fe_2O_3 is 6+, the oxidation number of each Fe ion is +3.

Step 2: Identify which atoms are oxidized and which are reduced. In this reaction, iron decreases in oxidation number from +3 to 0, a change of −3. Therefore, iron is reduced. Carbon increases in oxidation number from +2 to +4, a change of +2. Thus, carbon is oxidized.

Step 3: Use one bracketing line to connect the atoms that undergo oxidation and another such line to connect those that undergo reduction. Write the oxidation-number change at the midpoint of each line.

$$\overset{+3\ -2}{Fe_2O_3(s)} + \overset{+2-2}{CO(g)} \longrightarrow \overset{0}{Fe(s)} + \overset{+4-2}{CO_2(g)}$$

(+2 (oxidation) over the C atoms; −3 (reduction) under the Fe atoms)

Remember that a change in oxidation number represents the number of electrons transferred. Each carbon atom in CO loses 2 electrons in oxidation, and each iron atom in Fe_2O_3 accepts 3 electrons in reduction. As the equation is written, the number of electrons transferred in oxidation does not equal the number of electrons transferred in reduction. Step 4 will make the oxidation-number changes equal.

Step 4: Make the total increase in oxidation number equal to the total decrease in oxidation number by using appropriate coefficients. In this example, the oxidation-number increase should be multiplied by 3 and the oxidation-number decrease should be multiplied by 2, which gives an increase of +6 and a decrease of −6. This equalization can be achieved in the equation by placing the coefficient 2 in front of Fe on the right side and the coefficient 3 in front of both CO and CO_2. The formula Fe_2O_3 does not need a coefficient because the formula already indicates 2 Fe.

$$\underbrace{Fe_2O_3(s) + 3CO(g)}_{2 \times (-3) = -6} \longrightarrow \overbrace{2Fe(s) + 3CO_2(g)}^{3 \times (+2) = +6}$$

Step 5: Finally, make sure the equation is balanced for both atoms and charge. If necessary, finish balancing the equation by inspection.

$$Fe_2O_3(s) + 3CO(g) \longrightarrow 2Fe(s) + 3CO_2(g)$$

Professional Development Note

Redox Reactions and Rockets

Evidence exists that the use of rockets—and of redox reactions to power them—began in the thirteenth century when Chinese armies used "arrows of flying fire" to defend their cities. These rockets were leather cylinders filled with gunpowder and mounted on a stick. It is generally thought that the gunpowder mixture originated in ninth-century China.

The essential components of a rocket propellant are a source of energy (the fuel) and an oxidizing agent to react with the fuel. When the mixture is ignited, the fuel is oxidized rapidly and the oxidizing agent is reduced. Gunpowder is a mixture of charcoal (carbon), sulfur, and potassium nitrate. It reacts explosively to produce potassium sulfide, gaseous carbon dioxide, and nitrogen. In the redox reaction, carbon is the fuel and other components are oxidizing agents.

SampleProblem 20.6

Balancing Redox Equations by Oxidation-Number Change

Balance this redox equation by using the oxidation-number-change method.

$$K_2Cr_2O_7(aq) + H_2O(l) + S(s) \longrightarrow KOH(aq) + Cr_2O_3(s) + SO_2(g)$$

1 Analyze **Identify the relevant concepts.** You can balance redox equations by determining changes in oxidation numbers and applying the five steps.

2 Solve **Apply concepts to this situation.**

Step 1: Assign oxidation numbers.

$$\overset{+1}{2}\overset{+6}{Cr}\overset{-2}{O_7}(aq) + \overset{+1}{H_2}\overset{-2}{O}(l) + \overset{0}{S}(s) \longrightarrow \overset{+1}{K}\overset{-2}{O}\overset{+1}{H}(aq) + \overset{+3}{Cr_2}\overset{-2}{O_3}(s) + \overset{+4}{S}\overset{-2}{O_2}(g)$$

Step 2: Identify the atoms that are oxidized and reduced.

Cr is reduced. S is oxidized.

Step 3: Connect the atoms that change in oxidation number. Indicate the signs and magnitudes of the changes.

$$\overset{+6}{K_2Cr_2O_7}(aq) + H_2O(l) + \overset{0}{S}(s) \longrightarrow KOH(aq) + \overset{+3}{Cr_2O_3}(s) + \overset{+4}{SO_2}(g)$$

(−3) × 2 = −6

Step 4: Balance the increase and decrease in oxidation numbers.

$$2\overset{+6}{K_2Cr_2O_7}(aq) + H_2O(l) + 3\overset{0}{S}(s) \longrightarrow KOH(aq) + 2\overset{+3}{Cr_2O_3}(s) + 3\overset{+4}{SO_2}(g)$$

(4)(−3) = −12

(3)(+4) = +12

Four chromium atoms must be reduced (4 × (−3) = −12 decrease) for every three sulfur atoms that are oxidized (3 × (+4) = +12 increase). Put the coefficient 3 in front of S and SO_2, and the coefficient 2 in front of $K_2Cr_2O_7$ and Cr_2O_3.

Step 5: Check the equation and balance by inspection if necessary.

$$2K_2Cr_2O_7(aq) + 2H_2O(l) + 3S(s) \longrightarrow 4KOH(aq) + 2Cr_2O_3(s) + 3SO_2(g)$$

23. Balance each redox equation using the oxidation-number-change method.

a. $KClO_3(s) \longrightarrow KCl(s) + O_2(g)$

b. $HNO_2(aq) + HI(aq) \longrightarrow NO(g) + I_2(s) + H_2O(l)$

24. Balance each redox equation using the oxidation-number-change method.

a. $Bi_2S_3(s) + HNO_3(aq) \longrightarrow Bi(NO_3)_3(aq) + NO(g) + S(s) + H_2O(l)$

b. $SbCl_5(aq) + KI(aq) \longrightarrow SbCl_3(aq) + KCl(aq) + I_2(s)$

Foundations for Math

LEAST COMMON MULTIPLE (LCM) Explain to students that they can use the LCM to balance redox equations. They should find the LCM of the absolute values of the changes in oxidation number of the reducing agent and the oxidizing agent. Remind students that the LCM is the smallest number that is a multiple of two or more numbers.

In **Sample Problem 20.6** the changes in oxidation number are –3 and +4. Show students how to find the LCM of 3 and 4.

Multiples of 3: 3, 6, 9, **12**, 15, 18

Multiples of 4: 4, 8, **12**, 16, 20

Point out that the smallest number that is a multiple of 3 and 4 is 12.

Explain

Sample Practice Problem

Write chemical equations for the following redox reactions. Balance each equation by using the oxidation-number-change method.

A. Solid barium chlorate decomposes when heated, yielding solid barium chloride and gaseous oxygen. *($Ba(ClO_3)_2$ (s) → $BaCl_2$(s) + $3O_2$(g))*

B. Solid lead(II) sulfide reacts with gaseous oxygen to produce solid lead(II) oxide and gaseous sulfur dioxide. *($2PbS$(s)+ $3O_2$(g) → $2PbO$(s) + $2SO_2$(g))*

Answers

23. **a.** 2, 2, 3

b. 2, 2, 2, 1, 2

24. **a.** 1, 8, 2, 2, 3, 4

b. 1, 2, 1, 2, 1

Explain

Balancing Redox Equations

USE VISUALS Have students study Table 20.2. **Ask** What are the oxidation numbers of all the elements in H_2SO_4? *(H is 1, S is 6, and O is 2.)* What are the oxidation numbers of all the elements in $Na_2S_2O_3$? *(Na is 1, S is 2, and O is 2.)*

APPLY CONCEPTS Tell students that the underlying assumption when using half-reactions is that any redox reaction can always be considered as two separate processes occurring simultaneously. Therefore, the "whole" reaction can be thought of as the sum of two halves—an oxidation reaction and a reduction reaction. Go through the half-reaction method with a specific example, clearly explaining each step. Emphasize the following points:

- Oxidation half-reactions are always written with the electrons on the right-hand side of the equation.
- Reduction half-reactions are always written with the electrons on the left-hand side of the equation.

CRITICAL THINKING Point out that in Step 3, H_2O and either H^+ or OH^- can be added to either side of an equation to balance O and H atoms. **Ask** Why is it acceptable that these ions can be added to either side of the equation? *(The reaction itself is not changed by doing so; rather, the medium of the reaction is simply being defined. In an acidic solution, H ions are present in excess. In a basic solution, OH ions are present in excess.)*

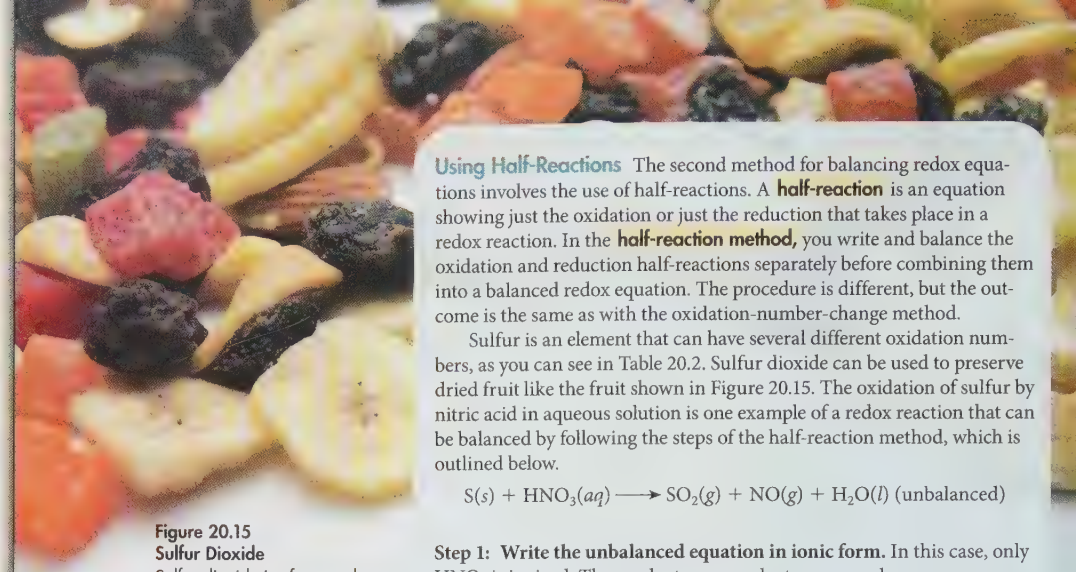

Figure 20.15
Sulfur Dioxide
Sulfur dioxide is often used to preserve dried fruits.

Table 20.2
Oxidation Numbers of Sulfur in Different Substances

Substance	Oxidation number
H_2SO_4	+6
SO_3	+6
H_2SO_3	+4
SO_2	+4
$Na_2S_2O_3$	+2
SCl_2	+2
S_2Cl_2	+1
S	0
H_2S	−2

Using Half-Reactions The second method for balancing redox equations involves the use of half-reactions. A **half-reaction** is an equation showing just the oxidation or just the reduction that takes place in a redox reaction. In the **half-reaction method,** you write and balance the oxidation and reduction half-reactions separately before combining them into a balanced redox equation. The procedure is different, but the outcome is the same as with the oxidation-number-change method.

Sulfur is an element that can have several different oxidation numbers, as you can see in Table 20.2. Sulfur dioxide can be used to preserve dried fruit like the fruit shown in Figure 20.15. The oxidation of sulfur by nitric acid in aqueous solution is one example of a redox reaction that can be balanced by following the steps of the half-reaction method, which is outlined below.

$$S(s) + HNO_3(aq) \longrightarrow SO_2(g) + NO(g) + H_2O(l) \text{ (unbalanced)}$$

Step 1: Write the unbalanced equation in ionic form. In this case, only HNO_3 is ionized. The products are covalent compounds.

$$S(s) + H^+(aq) + NO_3^-(aq) \longrightarrow SO_2(g) + NO(g) + H_2O(l)$$

Step 2: Write separate half-reactions for the oxidation and reduction processes. Sulfur is oxidized in this reaction because its oxidation number increases from 0 to +4. Nitrogen is reduced because its oxidation number decreases from +5 to +2.

Oxidation half-reaction: $\overset{0}{S}(s) \longrightarrow \overset{+4}{SO_2}(g)$

Reduction half-reaction: $\overset{+5}{NO_3^-}(aq) \longrightarrow \overset{+2}{NO}(g)$

Notice that H^+ ions and H_2O are not included in the half-reactions because they are neither oxidized nor reduced. However, they will be used in balancing the half-reactions.

Step 3: Balance the atoms in the half-reactions.
a. Balance the oxidation half-reaction. Sulfur is already balanced in the half-reaction, but oxygen is not. This reaction takes place in acid solution, so H_2O and $H^+(aq)$ are present and can be used to balance oxygen and hydrogen as needed. If the reaction takes place in basic solution, H_2O and OH^- are used to balance these species. Add two molecules of H_2O on the left to balance the oxygen in the half-reaction.

$$2H_2O(l) + S(s) \longrightarrow SO_2(g)$$

Oxygen is now balanced, but four hydrogen ions ($4H^+$) must be added to the right to balance the hydrogen on the left.

$$2H_2O(l) + S(s) \longrightarrow SO_2(g) + 4H^+(aq)$$

This half-reaction is now balanced in terms of atoms. Note that it is not balanced in terms of charge. The charges will be balanced in Step 4.

Differentiated Instruction

LPR LESS PROFICIENT READERS Balancing redox reactions by the half-reaction method is a lengthy process that requires good organizational skills and attention to detail. Students who are impatient or easily frustrated may have difficulty with these problems. Working in small groups can help them organize their efforts. Supervise the work closely to be sure each student is contributing.

L1 STRUGGLING STUDENTS Hang a large sheet of butcher paper on the wall to teach example problems involving the half-reaction method. Use the think-aloud method and ask questions such as "What is the charge of this element?" and "Should I add water and hydrogen?" Have a student volunteer use sticky notes to place the answers to these questions in the proper locations on the reactions.

b. Balance the reduction half-reaction. Nitrogen is already balanced. Add two molecules of H_2O on the right to balance the oxygen.

$$NO_3^-(aq) \longrightarrow NO(g) + 2H_2O(l)$$

Oxygen is balanced, but four hydrogen ions ($4H^+$) must be added to the left to balance hydrogen.

$$4H^+(aq) + NO_3^-(aq) \longrightarrow NO(g) + 2H_2O(l)$$

This half-reaction is now balanced in terms of atoms.

Step 4: Add enough electrons to one side of each half-reaction to balance the charges. Note that neither half-reaction is balanced for charge. Four electrons are needed on the right side in the oxidation half-reaction.

Oxidation: $2H_2O(l) + S(s) \longrightarrow SO_2(g) + 4H^+(aq) + 4e^-$

Three electrons are needed on the left side in the reduction half-reaction.

Reduction: $4H^+(aq) + NO_3^-(aq) + 3e^- \longrightarrow NO(g) + 2H_2O(l)$

Each half-reaction is now balanced with respect to both atoms and charge.

Step 5: Multiply each half-reaction by an appropriate number to make the numbers of electrons equal in both. The number of electrons lost in oxidation must equal the number of electrons gained in reduction. In this case, the oxidation half-reaction is multiplied by 3 and the reduction half-reaction is multiplied by 4. Therefore, the number of electrons lost in oxidation and the number of electrons gained in reduction both equal 12.

Oxidation: $6H_2O(l) + 3S(s) \longrightarrow 3SO_2(g) + 12H^+(aq) + 12e^-$

Reduction: $16H^+(aq) + 4NO_3^-(aq) + 12e^- \longrightarrow 4NO(g) + 8H_2O(l)$

Step 6: Add the balanced half-reactions to show an overall equation.

$$6H_2O(l) + 3S(s) + 16H^+(aq) + 4NO_3^-(aq) + 12e^- \longrightarrow 3SO_2(g) + 12H^+(aq) + 12e^- + 4NO(g) + 8H_2O(l)$$

Then, subtract terms that appear on both sides of the equation.

$$3S(s) + 4H^+(aq) + 4NO_3^-(aq) \longrightarrow 3SO_2(g) + 4NO(g) + 2H_2O(l)$$

Step 7: Add the spectator ions and balance the equation. Recall that spectator ions are present but do not participate in or change during a reaction. Because none of the ions in the reactants appear in the products, there are no spectator ions in this particular example. The balanced equation is correct. However, it can be written to show the HNO_3 as not ionized.

$$3S(s) + 4HNO_3(aq) \longrightarrow 3SO_2(g) + 4NO(g) + 2H_2O(l)$$

Check for Understanding

BIG IDEA How can you balance redox equations?

Assess students' understanding of balancing redox equations by asking them to write a compare-and-contrast statement comparing the oxidation-number-change method to the half-reaction method. Answers may be in the form of a written summary or a two-column table.

ADJUST INSTRUCTION If students are having difficulty with this exercise, have them read the first paragraph of the Balancing Redox Equations section and review the listed steps for each method.

Explore

Teacher Demo

PURPOSE Students will observe the oxidation process in everyday foods.

MATERIALS potatoes; apples; beakers; water; boiled water; lemon juice; carbonated beverage; sugar, salt and vinegar solutions; paper towels

PROCEDURE Students should be familiar with the "browning" of sliced potatoes or apples upon exposure to oxygen. The oxidation is catalyzed by enzymes in food. Explain that oxidation can be prevented or slowed down. The outer skin provides a natural physical barrier to oxygen. Chemical protection can be provided by antioxidants, which act as reducing agents, or by inhibiting enzymes. Liquids such as lemon juice contain antioxidants.

Have students form groups of two or three, and give each group a potato and an apple. Provide beakers filled with tap water, water that has been boiled to exclude most dissolved oxygen, lemon juice, a carbonated beverage, plus sugar, salt, and vinegar solutions. Have students quickly cut the potato and apple into slices and immediately place a slice in each beaker. Have them label areas on the paper towels to match the labels on the beakers. Have them remove the slices after they have soaked for several minutes and place them on the paper towels. Have them make periodic observations of the slices to determine the degree of "browning." On the basis of their observations, students should decide which liquids offer the best protection. Have them try to explain why the liquids are good or bad protectants. Ask students to present their findings in the form of a poster, a computerized slide show presentation, or a written or oral report.

Explain

Balancing Redox Equations

APPLY CONCEPTS When showing students various examples using the half-reaction method for balancing redox equations, students may question why hydrogen ions, hydroxide ions, or water molecules can be added to an equation during the process. Remind them that the aqueous solutions in which these reactions take place contain an abundance of these species. **Ask** Why is there an abundance of these species? *(Water exists in a state of equilibrium. Water molecules are constantly dissociating into hydrogen ions and hydroxide ions, making them available to take part in the half-reactions.)*

CRITICAL THINKING A reaction in which the same compound is both oxidized and reduced is called *disproportional*. When NO_2 is dissolved in water, it disproportionates to form nitric acid (HNO_3) and nitric oxide (NO). Have students balance the equation for this reaction.

($3NO_2(g) + H_2O(l) \rightarrow +2H+(aq)\ 2NO_3^-(aq) + NO(g)$)

Extend

Connect to BIOLOGY

Explain to the class that some organisms produce light by means of oxidation-reductions in a process known as bioluminescence. Have students examine this process to determine what is involved. *(Light is given off when one of a class of compounds called luciferins is oxidized by combining with oxygen. A product of these reactions is energy in the form of light.)* Ask students to determine the function bioluminescence serves for fireflies and squids. *(Fireflies use bioluminescence to attract mates; squids release a glowing cloud of "ink" to confuse and escape from their predators.)*

Sample Problem 20.7

Balancing Redox Equations by Half-Reactions

Balance this redox equation using the half-reaction method.

$$KMnO_4(aq) + HCl(aq) \longrightarrow MnCl_2(aq) + Cl_2(g) + H_2O(l) + KCl(aq)$$

1 Analyze **Identify the relevant concepts.** You can use the seven steps of the half-reaction method.

2 Solve **Apply concepts to this problem.**

Step 1: Write the equation in ionic form.

$$K^+(aq) + MnO_4^-(aq) + H^+(aq) + Cl^-(aq) \longrightarrow Mn^{2+}(aq) + 2Cl^-(aq) + Cl_2(g) + H_2O(l) + K^+(aq) + Cl^-(aq)$$

Step 2: Write half-reactions. Determine the oxidation and reduction process.

$$\text{Oxidation half-reaction: } \overset{-1}{Cl^-} \longrightarrow \overset{0}{Cl_2}$$

$$\text{Reduction half-reaction: } \overset{+7}{MnO_4^-} \longrightarrow \overset{+2}{Mn^{2+}}$$

Step 3: Balance the atoms in each half-reaction. The solution is acidic, so use H_2O and H^+ to balance the oxygen and hydrogen.

$$\text{Oxidation: } 2Cl^-(aq) \longrightarrow Cl_2(g) \quad \text{(atoms balanced)}$$

$$\text{Reduction: } MnO_4^-(aq) + 8H^+(aq) \longrightarrow Mn^{2+}(aq) + 4H_2O(l) \quad \text{(atoms balanced)}$$

Step 4: Balance the charges by adding electrons.

$$\text{Oxidation: } 2Cl^-(aq) \longrightarrow Cl_2(g) + 2e^- \quad \text{(charges balanced)}$$

$$\text{Reduction: } MnO_4^-(aq) + 8H^+(aq) + 5e^- \longrightarrow Mn^{2+}(aq) + 4H_2O(l) \quad \text{(charges balanced)}$$

Step 5: Make the numbers of electrons equal. Multiply the oxidation half-reaction by 5 and the reduction half-reaction by 2.

$$\text{Oxidation: } 10Cl^-(aq) \longrightarrow 5Cl_2(g) + 10e^-$$

$$\text{Reduction: } 2MnO_4^-(aq) + 16H^+(aq) + 10e^- \longrightarrow 2Mn^{2+}(aq) + 8H_2O(l)$$

Step 6: Add the half-reactions. Then, subtract the terms that appear on both sides.

$$10Cl^-(aq) + 2MnO_4^-(aq) + 16H^+(aq) + \cancel{10e^-} \longrightarrow 5Cl_2(g) + \cancel{10e^-} + 2Mn^{2+}(aq) + 8H_2O(l)$$

Step 7: Add the spectator ions, making sure the charges and atoms are balanced.

$$10Cl^- + 2MnO_4^- + 2K^+ + 16H^+ + 6Cl^- \longrightarrow 5Cl_2 + 2Mn^{2+} + 4Cl^- + 8H_2O + 2K^+ + 2Cl^-$$

Foundations for Math

LIKE TERMS Remind students that in algebra they learned that they can add or subtract terms in an expression or equation only if the terms are like terms. Explain that like terms have the same variable raised to the same power, but the coefficients may differ.

- $3x$ and $5x$ are like terms.
- $3x$ and $4x^2$ are not like terms.

In **Sample Problem 20.7**, point out that the step following Step 7 is similar to combining like terms. Point out that among the reactants, 10Cl and 6Cl are like terms and can be combined to get a sum of 16Cl. Point out that among the products, only 4Cl and 2Cl can be combined to get a sum of 6Cl; $5Cl_2$ is not a like term.

Combine the spectator and nonspectator Cl^- on each side.

$$16Cl^-(aq) + 2MnO_4^-(aq) + 2K^+(aq) + 16H^+(aq) \longrightarrow 5Cl_2(g) + 2Mn^{2+}(aq) + 6Cl^-(aq) + 8H_2O(l) + 2K^+(aq)$$

Show the balanced equation for the substances given in the question (rather than for ions).

$$2KMnO_4(aq) + 16HCl(aq) \longrightarrow 2MnCl_2(aq) + 5Cl_2(g) + 8H_2O(l) + 2KCl(aq)$$

25. The following reaction takes place in an acidic solution. Balance the equation using the half-reaction method.
$Sn^{2+}(aq) + Cr_2O_7^{2-}(aq) \longrightarrow Sn^{4+}(aq) + Cr^{3+}(aq)$

26. The following reaction takes place in basic solution. Balance the equation using the half-reaction method.
$Zn(s) + NO_3^-(aq) \longrightarrow NH_3(aq) + Zn(OH)_4^{2-}(aq)$

For a solution that is basic, use H_2O and OH^- in Step 3 to balance the atoms.

20.3 LessonCheck

27. **Identify** What are the two classes of chemical reactions?

28. **Compare** What are two different methods for balancing a redox equation?

29. **Calculate** Balance each redox equation, using the oxidation-number-change method.

a. $ClO_3^-(aq) + I^-(aq) \longrightarrow Cl^-(aq) + I_2(aq)$ [acidic solution]

b. $C_2O_4^{2-}(aq) + MnO_4^-(aq) \longrightarrow Mn^{2+}(aq) + CO_2(g)$ [acidic solution]

c. $Br_2(l) + SO_2(g) \longrightarrow Br^-(aq) + SO_4^{2-}(aq)$ [acidic solution]

30. **Calculate** Use the half-reaction method to write a balanced ionic equation for each reaction.

a. $Zn(s) + As_2O_3(aq) \longrightarrow AsH_3(aq) + Zn^{2+}(aq)$ [basic solution]

b. $NiO_2(s) + S_2O_3^{2-}(aq) \longrightarrow Ni(OH)_2(s) + SO_3^{2-}(aq)$ [basic solution]

31. **Identify** Review the equations for the production of sodium, bromine, and iodine found on pages R2 and R28 of the Elements Handbook. Identify the oxidizing agent and the reducing agent in each reaction.

Lesson Check Answers

27. Reactions in which electrons are transferred from one reacting species to another (redox reactions) and reactions that do not involve a transfer of electrons.

28. The oxidation-number-change method and the half-reaction method.

29. **a.** $ClO_3^-(aq) + 6I^-(aq) + 6H^+(aq) \rightarrow Cl^-(aq) + 3I_2(aq) + 3H_2O(l)$

b. $5C_2O_4^{2-}(aq) + 2MnO_4^-(aq) + 16H^+(aq) \rightarrow 2Mn^{2+}(aq) + 10CO_2(g) + 8H_2O(l)$

c. $Br_2(l) + SO_2(g) + 2H_2O(l) \rightarrow 2Br^-(aq) + SO_4^{2-}(aq) + 4H^+(aq)$

30. **a.** $6Zn(s) + As_2O_3(aq) + 9H_2O(l) \rightarrow 6Zn^{2+}(aq) + 2AsH_3(aq) + 12OH^-(aq)$

b. $2NiO_2(s) + S_2O_3^{2-}(aq) + H_2O(l) + 2OH^-(aq) \rightarrow 2SO_3^{2-}(aq) + 2Ni(OH)_2(s)$

31. oxidizing agent, Na^+; reducing agent, Cl^-

oxidizing agent, Cl_2; reducing agent, Br^-

oxidizing agent, IO_3^- or I^{5+}; reducing agent, HSO_3^- or S^{4+}

Evaluate

Informal Assessment

In order to assess students' knowledge of redox reactions, pose the following questions. **Ask** Copper(II) hydroxide ($Cu(OH)_2$) is converted to copper(II) oxide (CuO) and water upon heating. Is this a redox reaction? Why or why not? *(No, it is not; none of the elements undergo a change in oxidation number.)* **Ask** Copper(II) oxide (CuO) is converted to copper metal upon heating in the presence of carbon. Is this a redox reaction? Why or why not? *(Yes, copper is reduced; its oxidation number decreases from 2 to 0. Carbon is oxidized; its oxidation number increases from 0 to 4 when it is converted to CO_2.)*

Then have students complete the 20.3 Lesson Check.

Reteach

Point out that the distinguishing feature of redox reactions is the change in oxidation numbers that occurs. To decide whether a given reaction is a redox reaction, students need only compare the oxidation numbers of the reactants to the oxidation numbers of the products. If a change has occurred, the reaction is a redox reaction.

Answers

25. $3Sn^{2+} + Cr_2O_7^{2-} + 14H^+ \rightarrow 3Sn^{4+} + 2Cr^{3+} + 7H_2O$

26. $4Zn + NO_3^- + 6H_2O + 7OH^- \rightarrow 4Zn(OH)_4^{2-} + NH_3$

CHEMISTRY & YOU Have students consider the relationship between color and light. Point out that color, or lack of color, in a gemstone is related to its ability to transmit light. Colorless stones transmit all wavelengths of visible light. Impurities, such as the ions listed in the text, absorb certain wavelengths and transmit others. Aquamarine is blue because its impurities transmit the wavelengths responsible for creating the characteristic blue color of that stone, and absorb all other wavelengths. Each type of stone in the photographs has its own absorption spectrum.

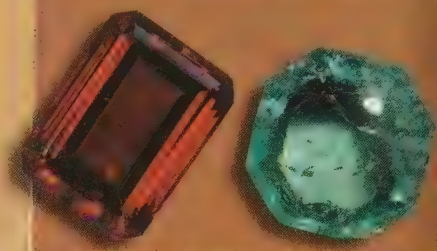
Point out that while heat can be used to change the color of some stones, the color of other stones can be changed just by changing the type of light used to illuminate them. In these stones, the oxidation state of the impurity is not changed. Alexandrite, another stone that contains Cr^{3+}, usually appears purple in sunlight. However, in candlelight it appears red and in fluorescent light it appears blue. Pose the following question to students: *What is the most likely explanation for the different colors observed in alexandrite?* You may need to assist students in the following ways:

- The chromium is not oxidized or reduced.
- Sunlight contains all wavelengths of visible light.
- Candlelight is made up mostly of red wavelengths.
- Fluorescent light is made up mostly of blue wavelengths.
- Purple light can be transmitted by a stone that has the ability to transmit both red and blue wavelengths.

Answers

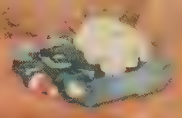
1. +2, +3, +2, +3
2. Reduced; the oxidation number changes from +3 to +2.

Mineral Colors



Beryl is a rather unassuming colorless mineral on its own. But when impurities caused by trace amounts of certain elements are present in the crystal, beryl transforms into brilliant green emeralds, pale blue aquamarines, light pink morganites, golden yellow heliodors, and ruby-toned red beryls.

Transition metal elements, such as iron, chromium, and manganese, are the most common causes of color in minerals. The type, amount, and oxidation number of the transition metal as well as the compound it forms determine the color. Most transition metals have two or more oxidation numbers, each of which can be responsible for a different color in a mineral. For example, Fe^{2+} gives aquamarine its blue color, while Fe^{3+} makes heliodor yellow. Mn^{2+} is responsible for morganite's pink hue, and Mn^{3+} turns beryl a rich red.



Changing the oxidation state of the impurity can change the color of the mineral. Heating a yellow beryl, for example, changes the Fe^{3+} in the stone to Fe^{2+}, turning the beryl blue. And heating a purple amethyst (quartz colored by Fe^{3+}) produces yellow-brown citrine (Fe^{2+}).

ADDING COLOR TO GEMS
Transition elements are responsible for creating different colors of beryl.

ONE STATE, DIFFERENT COLORS
Chromium(III) produces both the red of rubies and the green of emeralds by forming different compounds in the base mineral.

DIGGING IN THE DIRT
Beryl is obtained through mining. In this mine in Madagascar, workers are digging by hand to find beryl.

Take It Further

1. Identify Determine the oxidation number for each of the following transition metal ions: Fe^{2+}, Fe^{3+}, Mn^{2+}, Mn^{3+}.

2. Apply Concepts When amethyst is heated to produce citrine, is the iron in the mineral oxidized or reduced? Explain your answer.

Differentiated Instruction

L3 ADVANCED STUDENTS Explain that synthetic gemstones have the same chemical makeup and physical properties as their natural counterparts. Challenge students to research the processes involved in creating synthetic versions of the gemstones discussed in this feature and share their results with the class.

L1 LESS PROFICIENT READERS Have students organize the minerals, their impurities and their colors in a three-column table. Have students refer to their tables during discussion to help them identify the colors that result from changes in oxidation state.

Small-Scale Lab

Half-Reactions

Purpose

To observe redox reactions and to write half-reactions that describe them

Materials

- ruler
- chemicals listed in the grid
- reaction surface

Procedure

1. On separate sheets of paper, draw two grids similar to the one below.

	HCl	HNO_3	H_2SO_4
Zn			
Mg			
Cu			
Fe			

2. Make each square 2 cm on each side. Place a reaction surface over one of the grids and add one drop of each acid solution to one piece of each metal, as shown above. Use the second grid as a data table to record your observations for each solution.

Analyze

Using your data, answer the following questions.

1. Explain Which metal is the most reactive? How do you know? Which metal did not react with any of the acids?

2. Infer List the metals in order of decreasing reactivity.

3. Infer What is the chemical formula of the gas produced in each reaction?

4. Calculate An active metal reacts with an acid to produce hydrogen gas and a salt. Write chemical equations and net ionic equations to describe the reactions you observed. Are all of these redox reactions? Explain.

5. Calculate The half-reaction for the oxidation of zinc is shown below.

$$Zn(s) \longrightarrow Zn^{2+}(aq) + 2e^-$$

Write the oxidation half-reaction for the other metals that react.

6. Calculate The half-reaction for the reduction of hydrogen from the acid is shown below.

$$2H^+ + 2e^- \longrightarrow H_2(g)$$

Notice that this half-reaction is the same for all the acids. Demonstrate how adding this half-reaction to each oxidation half-reaction results in the overall net ionic equations.

You're the Chemist

The following small-scale activities allow you to develop your own procedures and analyze the results.

1. Analyze Data Pennies minted after 1982 are made of zinc with a thin copper coating. Use a penny that has been damaged so that a portion of the zinc shows through to compare the reactivity of the zinc and the copper toward various acids.

2. Design an Experiment Many household products, such as toilet-bowl cleaners and vinegar, contain acids. Design and carry out experiments to find out if these products also react with metals.

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of two to complete the lab. Be sure to pair ELLs with writing/reading partners so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH As you place the chemicals on the grid, state each chemical name aloud. Students can practice stating the name of each chemical. Allow students to respond orally to the Analyze questions.

INTERMEDIATE: LOW/HIGH Allow students to present their results by using symbols as needed. Orally question students about their findings.

ADVANCED

LOW Have students write draft responses to the Calculate questions from the lab and then revise their answers after consultation with you.

HIGH Ask students to complete the You're the Chemist activities with clearly planned oral responses to the class. Allow time for classmates to ask questions.

Small-Scale Lab

OBJECTIVE After completing this activity, students will be able to write half-reactions to describe observed redox reactions between acids and metals.

PREP TIME 45 minutes

CLASS TIME 45 minutes

ADVANCE PREPARATION Prepare the following solutions.

Solution	Preparation
1.0*M* HCl	82 mL of 12*M* in 1.0 L
1.0*M* HNO_3	63 mL of 15.8*M* in 1.0 L
1.0*M* H_2SO_4	56 mL of 18*M* in 1.0 L

SAFETY Always add acid to water carefully and slowly.

TEACHING TIPS Emphasize that a half-reaction shows what happens to electrons in redox reactions. Use magnesium turnings, or cut magnesium ribbon into 0.5-cm pieces. Use galvanized nails for zinc, staples from a stapler for iron, and pennies for copper. Recycle all the metals except the staples.

ANALYZE AND CONCLUDE

1. Mg is most reactive because it bubbles most vigorously. Cu does not react. The order of reactivity is Mg > Zn > Fe > Cu.
2. $H_2(g)$ is produced in all the reactions.
3. $Mg(s) + 2HCl(aq) \rightarrow H_2(g) + MgCl_2(aq)$
   $Mg(s) + 2H^+(aq) \rightarrow H_2(g) + Mg^{2+}(aq)$
   Reactions of HCl with Zn and Fe are similar.
   All are redox reactions because the oxidation numbers of reactants change.
4. $Mg(s) \rightarrow Mg^{2+}(aq) + 2e^-$ $Cu(s) \rightarrow Cu^{2+}(aq) + 2e^-$
   $Fe(s) \rightarrow Fe^{2+}(aq) + 2e^-$
5. $2H^+ + 2e^- \rightarrow H_2(g)$
   $Mg(s) \rightarrow Mg^{2+}(aq) + 2e^-$
   $2H^+ + Mg(s) \rightarrow H_2(g) + Mg^{2+}(aq)$

YOU'RE THE CHEMIST

1. Add a drop of any acid to the damaged part of the penny and notice that only the zinc interior reacts.
2. Vinegar and many toilet-bowl cleaners dissolve metals. Keep products containing acids away from metal pipes and fixtures.

FOR ENRICHMENT Have students research the redox reactions that take place in the black-and-white photography process. Have them write half-reactions and complete redox equations for the reactions.

STUDY GUIDE

Evaluate

Review and Assessment Materials

WALK-THRU TUTORIALS Each of the Skills Tune-Up problems on the following page has an animated step-by-step tutorial that explains the problem-solving strategy in detail.

PROBLEM SETS Have students practice more redox reactions problems by using the Chapter 20 Online Problem Set.

MATH SKILLS REVIEW Have struggling students practice solving algebraic equations by using the MathXL learning module.

VIRTUAL LABS Have students complete a virtual lab as an in-class or take-home assignment to help reinforce the concepts involved in solving redox equations.

Study Tip

Tell students that organizing information will help them remember it more easily. Suggest that students write key information from the chapter on index cards or large self-stick notes and use them to create large concept maps.

20 Study Guide

BIG IDEA REACTIONS

Oxidation-reduction reactions always occur simultaneously in redox reactions. Losing electrons is oxidation. Gaining electrons is reduction. If oxygen is involved in the reaction, then the substance gaining oxygen is oxidized, while the substance losing oxygen is reduced. The species that is reduced is the oxidizing agent, while the oxidized species is the reducing agent. Redox reactions are identified by changes in oxidation number. Redox equations can be balanced by two methods, the oxidation-number-change method and by balancing the oxidation and reduction half-reactions.

20.1 The Meaning of Oxidation and Reduction

- A substance that undergoes oxidation gains oxygen or loses electrons, while a substance that undergoes reduction loses oxygen or gains electrons.
- The presence of salts and acids accelerates corrosion by producing conductive solutions that make electron transfer easier.

- oxidation-reduction reaction (693)
- redox reaction (693)
- oxidation (694)
- reduction (694)
- reducing agent (695)
- oxidizing agent (695)

20.2 Oxidation Numbers

- As a general rule, a bonded atom's oxidation number is the charge that it would have if the electrons in the bond were assigned to the atom of the more electronegative element.
- An increase in the oxidation number of an atom or ion indicates oxidation. A decrease in the oxidation number of an atom or ion indicates reduction.

- oxidation number (701)

20.3 Describing Redox Equations

- One class of chemical reactions is oxidation-reduction (redox) reactions, in which electrons are transferred from one reacting species to another. The other class includes all other reactions, in which no electron transfer occurs.
- To balance a redox equation using the oxidation-number change method, the total increase in oxidation number of the species oxidized must be balanced by the total decrease in the oxidation number of the species reduced.
- To balance a redox reaction using half-reactions, write separate half-reactions for the oxidation and the reduction. After you balance atoms in each half-reaction, balance electrons gained in the reduction with electrons lost in the oxidation.

- oxidation-number-change method (710)
- half-reaction (712)
- half-reaction method (712)

UbD Performance Tasks

PLAN AND PROVE! Have students create a pros and cons assessment of balancing redox equations by using changes in oxidation numbers versus balancing equations by using the half-reaction method. Students should provide examples supporting their opinions.

RESEARCHING REDOX Have students investigate and report via a computerized slide show presentation two different technological applications that utilize redox reactions. Students should include the equations and the corresponding half-reactions used in these applications. Students should summarize with a statement generalizing the ways in which their lives would differ if redox reactions did not exist.

Skills Tune-Up: Redox Reactions

Problem

Use the changes in oxidation number to identify which atoms are oxidized and which are reduced in each reaction.

$$2ZnS(s) + 3O_2(g) \longrightarrow 2ZnO(s) + 2SO_2(g)$$

The following reaction takes place in a basic solution. Use the half-reaction method to write a balanced ionic equation.

$$MnO_4^-(aq) + I^-(aq) \longrightarrow MnO_2(s) + I_2(s)$$

1 Analyze

Assign an oxidation number to each atom on both sides of the equation. A decrease in oxidation number indicates reduction. An increase in oxidation number indicates oxidation.

Follow the steps of the half-reaction method to balance the equation. Write separate half-reactions for the oxidation and the reduction. After you balance atoms in each half-reaction, balance electrons gained in the reduction with electrons lost in the oxidation.

2 Solve

Use the Rules for Assigning Oxidation Numbers to identify the oxidation number of each atom.

$$\overset{+2\ -2}{2ZnS}(s) + \overset{0}{3O_2}(g) \longrightarrow \overset{+2\ -2}{2ZnO}(s) + \overset{+4\ -2}{2SO_2}(g)$$

The oxidation number of sulfur increases from +2 to +4, so sulfur is oxidized.

The oxidation number of oxygen decreases from 0 to −2, so oxygen is reduced.

Remember that the sum of the oxidation numbers of the atoms in a neutral compound must equal zero.

Perform the steps below.

Step 1:

$$MnO_4^-(aq) + I^-(aq) \longrightarrow MnO_2(s) + I_2(s)$$

Step 2:

Oxidation half-reaction: $I^-(aq) \longrightarrow I_2(s)$

Reduction half-reaction: $MnO_4^-(aq) \longrightarrow MnO_2(s)$

Step 3:

Balance the oxidation half-reaction.

$I^-(aq) \longrightarrow I_2(s)$

$2I^-(aq) \longrightarrow I_2(s)$

Hint: First, balance the equation as though it is an acidic solution, using H^+ ions and H_2O. Then, add as many OH^- ions to each side of the equation as there are H^+ ions on one side.

Balance the reduction half-reaction.

$MnO_4^-(aq) \longrightarrow MnO_2(s) + 2H_2O$

$4H^+ + MnO_4^-(aq) \longrightarrow MnO_2(s) + 2H_2O$

$4OH^- + 4H^+ + MnO_4^-(aq) \longrightarrow MnO_2(s) + 2H_2O + 4OH^-$

$4H_2O + MnO_4^-(aq) \longrightarrow MnO_2(s) + 2H_2O + 4OH^-$

$2H_2O + MnO_4^-(aq) \longrightarrow MnO_2(s) + 4OH^-$

Step 4:

Oxidation: $2I^-(aq) \longrightarrow I_2(s) + 2e^-$

Reduction: $3e^- + 2H_2O + MnO_4^-(aq) \longrightarrow MnO_2(s) + 4OH^-$

Step 5:

Oxidation: $6I^-(aq) \longrightarrow 3I_2(s) + 6e^-$

Reduction: $6e^- + 4H_2O + 2MnO_4^-(aq) \longrightarrow 2MnO_2(s) + 8OH^-$

Step 6:

$6I^-(aq) + \cancel{6e^-} + 4H_2O + 2MnO_4^-(aq) \longrightarrow 3I_2(s) + \cancel{6e^-} + 2MnO_2(s) + 8OH^-$

$6I^-(aq) + 4H_2O + 2MnO_4^-(aq) \longrightarrow 3I_2(s) + 2MnO_2(s) + 8OH^-$

Focus on ELL

5 ASSESS UNDERSTANDING Preview the questions in the chapter assessment. Have students underline the academic or vocabulary words they do not understand or have trouble pronouncing. Review these words by stating them aloud and referring students to the word wall, a bilingual glossary, or a dictionary.

BEGINNING: LOW/HIGH Rephrase the directions in simplified English. Repeat the directions and emphasize key words.

INTERMEDIATE

LOW Allow students to use a bilingual glossary during the assessment.

HIGH Help students with questions that require an explanation by showing them how to outline their answers prior to writing.

ADVANCED: LOW/HIGH Guide students in using the Skills Tune-Up for this chapter to help with application problems.

Skills Review

Example and sample practice problems related to redox reactions can be found on the following pages:

LESSON 20.1 Identifying Oxidized and Reduced Reactants—page 695

LESSON 20.2 Assigning Oxidation Numbers to Atoms—page 703; Identifying Oxidized and Reduced Atoms—pages 705 and 706

LESSON 20.3 Identifying Redox Reactions—page 709; Balancing Redox Equations by Oxidation-Number Change—page 711; Balancing Redox Equations by Half-Reactions—page 714

Evaluate

Answers

LESSON 20.1

32. oxidation

33. The oxidizing agent is reduced.

34. **a.** $2Ba(s) + O_2(g) \rightarrow 2BaO(s)$; barium is oxidized
b. $CuO(s) + H_2(g) \rightarrow Cu(s) + H_2O(l)$; copper is reduced
c. $C_2H_4(g) + 3O_2(g) \rightarrow 2CO_2(g) + 2H_2O(l)$; carbon is oxidized
d. $3CaO(s) + 2Al(s) \rightarrow Al_2O_3(s) + 3Ca(s)$; calcium is reduced

35. **a.** oxidation
b. oxidation
c. oxidation
d. oxidation

36. **a.** oxidizing agent
b. reducing agent
c. oxidizing agent
d. oxidizing agent

37. **a.** H_2 is oxidized; S is reduced.
b. N_2 is reduced; H_2 is oxidized.
c. S is oxidized; O_2 is reduced.
d. H_2 is oxidized; O_2 is reduced.

38. **a.** H_2 is the reducing agent; S is the oxidizing agent.
b. N_2 is the oxidizing agent; H_2 is the reducing agent.
c. S is the reducing agent; O_2 is the oxidizing agent.
d. H_2 is the reducing agent; O_2 is the oxidizing agent.

LESSON 20.2

39. An oxidation number is the charge an atom would have if the electrons in each bond were assigned to the atoms of the more electronegative element.

40. c is false.

41. **a.** 2
b. 3
c. Na, 1; Cr, 6
d. 5
e. 7

42. **a.** O, 2; H, 1
b. P, 5; O, 2
c. I, 5; O, 2
d. H, 1; P, 5; O, 2
e. H, 1; S, 6; O, 2

LESSON 20.3

43. **a.** Al is oxidized; Mn is reduced.
b. K is oxidized; H is reduced.
c. Hg is reduced; O is oxidized.
d. P is oxidized; O is reduced.

20 Assessment

* Solutions appear in Appendix E

Lesson by Lesson

20.1 The Meaning of Oxidation and Reduction

32. What chemical process must always accompany a reduction process?

33. What happens to an oxidizing agent during a redox reaction?

***34.** Balance each redox equation and identify whether the first substance in each equation was oxidized or reduced.
a. $Ba(s) + O_2(g) \longrightarrow BaO(s)$
b. $CuO(s) + H_2(g) \longrightarrow Cu(s) + H_2O(l)$
c. $C_2H_4(g) + O_2(g) \longrightarrow CO_2(g) + H_2O(l)$
d. $CaO(s) + Al(s) \longrightarrow Al_2O_3(s) + Ca(s)$

35. Identify each process as either oxidation or reduction.
a. $Al \longrightarrow Al^{3+} + 3e^-$
b. $2Cl^- \longrightarrow Cl_2 + 2e^-$
c. $S^{2-} \longrightarrow S + 2e^-$
d. $Sr \longrightarrow Sr^{2+} + 2e^-$

***36.** Which of the following would most likely be oxidizing agents, and which would most likely be reducing agents? (*Hint:* Think in terms of tendencies to lose or gain electrons.)
a. Cl_2
b. K
c. Ag^+
d. Zn^{2+}

* **37.** Refer to the electronegativity values in Table 6.2 to determine which reactant is oxidized and which reactant is reduced in each reaction.
a. $H_2(g) + S(s) \longrightarrow H_2S(g)$
b. $N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$
c. $S(s) + O_2(g) \longrightarrow SO_2(g)$
d. $2H_2(g) + O_2(g) \longrightarrow 2H_2O(l)$

38. Identify the oxidizing agent and the reducing agent for each of the reactions in Problem 37.

20.2 Oxidation Numbers

39. In your own words, what is an oxidation number?

40. Which of these statements is false?
a. The oxidation number of an uncombined element is zero.
b. The sum of the oxidation numbers of the atoms in a polyatomic ion must equal the charge of the ion.
c. Every element has a single oxidation number.
d. The oxidation number of oxygen in a compound or a polyatomic ion is almost always −2.

41. Determine the oxidation number of each metal atom.
a. Ca^{2+} **b.** Al_2S_3 **c.** Na_2CrO_4 **d.** V_2O_5 **e.** MnO_4^-

***42.** Assign oxidation numbers to the atoms in the following ions:
a. OH^- **b.** PO_4^{3-} **c.** IO_3^- **d.** $H_2PO_4^-$ **e.** HSO_4^-

20.3 Describing Redox Equations

43. Use the changes in oxidation numbers to identify which atoms are oxidized and which are reduced in each reaction.
a. $Al(s) + MnO_2(s) \longrightarrow Al_2O_3(s) + Mn(s)$
b. $K(s) + H_2O(l) \longrightarrow KOH(aq) + H_2(g)$
c. $HgO(s) \longrightarrow Hg(l) + O_2(g)$
d. $P_4(s) + O_2(g) \longrightarrow P_4O_{10}(s)$

***44.** Balance each redox equation.
a. $Al(s) + Cl_2(g) \longrightarrow AlCl_3(s)$
b. $Al(s) + Fe_2O_3(s) \longrightarrow Al_2O_3(s) + Fe(s)$
c. $Cl_2(g) + KOH(aq) \longrightarrow KClO_3(aq) + KCl(aq) + H_2O(l)$
d. $HNO_3(aq) + H_2S(g) \longrightarrow S(s) + NO(g) + H_2O(l)$
e. $KIO_4(aq) + KI(aq) + HCl(aq) \longrightarrow KCl(aq) + I_2(s) + H_2O(l)$

***45.** Identify which of these unbalanced equations represent redox reactions.
a. $Li(s) + H_2O(l) \longrightarrow LiOH(aq) + H_2(g)$
b. $K_2Cr_2O_7(aq) + HCl(aq) \longrightarrow KCl(aq) + CrCl_3(aq) + H_2O(l) + Cl_2(g)$
c. $Al(s) + HCl(aq) \longrightarrow AlCl_3(aq) + H_2(g)$
d. $Cl_2(g) + H_2O(l) \longrightarrow HCl(aq) + HClO(aq)$
e. $I_2O_5(s) + CO(g) \longrightarrow I_2(s) + CO_2(g)$
f. $H_2O(l) + SO_3(g) \longrightarrow H_2SO_4(aq)$

44. **a.** $2Al(s) + 3Cl_2(g) \rightarrow 2AlCl_3(s)$
b. $2Al(s) + Fe_2O_3(s) \rightarrow Al_2O_3(s) + 2Fe(s)$
c. $3Cl_2(g) + 6KOH(aq) \rightarrow KClO_3(aq) + 5KCl(aq) + 3H_2O(l)$
d. $2HNO_3(aq) + 3H_2S(aq) \rightarrow 3S(s) + 2NO(g) + 4H_2O(l)$
e. $KIO_4(aq) + 7KI(aq) + 8HCl(aq) \rightarrow 8KCl(aq) + 4I_2(s) + 4H_2O(l)$

45. redox: a, b, c, d, e

*46. Use the half-reaction method to write a balanced ionic equation for each reaction. All are acidic solutions.

a. $CuS(s) + NO_3^-(aq) \longrightarrow Cu(NO_3)_2(aq) + NO_2(g) + SO_2(g)$

b. $I^-(aq) + NO_3^-(aq) \longrightarrow I_2(s) + NO(g)$

*47. Use the half-reaction method to write a balanced ionic equation for each reaction. All are basic solutions.

a. $MnO_4^-(aq) + ClO_2^-(aq) \longrightarrow MnO_2(s) + ClO_4^-(aq)$

b. $Cr^{3+}(aq) + ClO^-(aq) \longrightarrow CrO_4^{2-}(aq) + Cl^-(aq)$

c. $Mn^{3+}(aq) + I^-(aq) \longrightarrow Mn^{2+}(aq) + IO_3^-(aq)$

Understand Concepts

48. Balance the equations in Problem 46 by an appropriate method.

49. Balance the equations in Problem 47 by an appropriate method.

*50. Determine the oxidation number of phosphorus in each substance.

a. P_4O_8
b. PO_4^{3-}
c. P_2O_5
d. P_4O_6
e. $H_2PO_4^-$
f. PO_3^{3-}

51. What is the oxidation number for chromium in each of these compounds?

a. K_2CrO_4 b. Cr_2O_3

52. Identify the element oxidized, the element reduced, the oxidizing agent, and the reducing agent in each unbalanced redox equation.

a. $MnO_2(s) + HCl(aq) \longrightarrow MnCl_2(aq) + Cl_2(g) + H_2O(l)$

b. $Cu(s) + HNO_3(aq) \longrightarrow Cu(NO_3)_2(aq) + NO_2(g) + H_2O(l)$

c. $P(s) + HNO_3(aq) + H_2O(l) \longrightarrow NO(g) + H_3PO_4(aq)$

d. $Bi(OH)_3(s) + Na_2SnO_2(aq) \longrightarrow Bi(s) + Na_2SnO_3(aq) + H_2O(l)$

53. Balance each redox equation in Problem 52 by using the oxidation-number-change method.

*54. An alcohol-content measuring device is used to test a person's breath for the alcohol ethanol, C_2H_5OH. In this test, ethanol reacts with an acidic solution of orange dichromate ion to form green chromium(III) ion.

$Cr_2O_7^{2-}(aq) + C_2H_5OH(aq) \longrightarrow Cr^{3+}(aq) + CO_2(g)$

The amount of color change is proportional to the amount of ethanol in the exhaled breath.

a. Balance this equation by the half-reaction method.
b. Is dichromate ion an oxidizing agent or a reducing agent?

55. The metallic element tungsten, used as a filament in incandescent light bulbs, is obtained by heating tungsten(VI) oxide with hydrogen.

$WO_3(s) + H_2(g) \longrightarrow W(s) + H_2O(g)$

a. Balance the equation.
b. What is the reducing agent in this reaction?
c. Which element undergoes an increase in oxidation number?

56. Silver tarnishes when it reacts with hydrogen sulfide in the air.

$Ag(s) + H_2S(g) \longrightarrow Ag_2S(s) + H_2(g)$

a. Is silver oxidized or reduced in this reaction?
b. Identify the oxidizing agent and the reducing agent.
c. Balance the equation.

57. The following equation represents an oxidation-reduction reaction that uses oxygen. Show how this reaction can also be defined as an oxidation-reduction reaction in terms of electron transfer.

$Pb(s) + O_2(g) \longrightarrow PbO(s)$

58. Does each of the following equations represent a redox reaction? Explain how you know.

a. $Bi_2O_3(s) + 3C(s) \longrightarrow 2Bi(s) + 3CO(g)$
b. $Cr_2O_3(s) + 3H_2S(g) \longrightarrow Cr_2S_3(s) + 3H_2O(l)$
c. $BCl_3(g) + 3H_2O(l) \longrightarrow H_3BO_3(s) + 3HCl(g)$

57. Lead atoms are oxidized by losing 2 electrons to form Pb^{2+} ions. Oxygen atoms are reduced by gaining 2 electrons to form O^{2-} ions.

58. a. Yes, the oxidation number of bismuth changes from 3 to zero; the oxidation number of carbon changes from zero to 2.
b. No, there is no change in oxidation number of any of the atoms in this reaction.
c. No, there is no change in oxidation number of any of the atoms in this reaction.

Evaluate

Answers

46. a. $CuS(s) + 8NO_3^-(aq) + 8H^+(aq) \rightarrow Cu(NO_3)_2(aq) + SO_2(g) + 6NO_2(g) + 4H_2O(l)$
b. $6I^-(aq) + 2NO_3^-(aq) + 8H^+(aq) \rightarrow 3I_2(s) + 2NO(g) + 4H_2O(l)$

47. a. $4MnO_4^-(aq) + 3ClO_2^-(aq) + 2H_2O(l) \rightarrow 4MnO_2(s) + 3ClO_4^-(aq) + 4OH^-(aq)$
b. $2Cr^{3+}(aq) + 3ClO^-(aq) + 10OH^-(aq) \rightarrow 2CrO_4^{2-}(aq) + 3Cl^-(aq) + 5H_2O(l)$
c. $6Mn^{3+}(aq) + I^-(aq) + 6OH^-(aq) \rightarrow 6Mn^{2+}(aq) + IO_3^-(aq) + 3H_2O(l)$

UNDERSTAND CONCEPTS

48. a. $4Al(s) + 3MnO_2(s) \rightarrow 2Al_2O_3(s) + 3Mn(s)$
b. $2K(s) + 2H_2O(l) \rightarrow 2KOH(aq) + H_2(g)$
c. $2HgO(s) \rightarrow 2Hg(l) + O_2(g)$
d. $P_4(s) + 5O_2(g) \rightarrow P_4O_{10}(s)$

49. a. $2Li(s) + 2H_2O(l) \rightarrow 2LiOH(aq) + H_2(g)$
b. $K_2Cr_2O_7(aq) + 14HCl(aq) \rightarrow 2KCl(aq) + 2CrCl_3(aq) + 7H_2O(l) + 3Cl_2(g)$
c. $2Al(s) + 6HCl(aq) \rightarrow 2AlCl_3(aq) + 3H_2(g)$
d. $Cl_2(g) + H_2O(l) \rightarrow HCl(aq) + HClO(aq)$
e. $I_2O_5(s) + 5CO(g) \rightarrow I_2(s) + 5CO_2(g)$
f. $H_2O(l) + SO_3(g) \rightarrow H_2SO_4(aq)$

50. a. 4
b. 5
c. 5
d. 3
e. 5
f. 3

51. K_2CrO_4, Cr 6; $K_2Cr_2O_7$, Cr 6

b. Cu oxidized, N reduced, N oxidizing agent, Cu reducing agent
c. P oxidized, N reduced, N oxidizing agent, P reducing agent
d. Sn oxidized, Bi reduced, Bi oxidizing agent, Sn reducing agent

53. a. $MnO_2(s) + 4HCl(aq) \rightarrow MnCl_2(aq) + Cl_2(g) + 2H_2O(l)$
b. $Cu(s) + 4HNO_3(aq) \rightarrow Cu(NO_3)_2(aq) + 2NO_2(g) + 2H_2O(l)$
c. $3P(s) + 5HNO_3(aq) + 2H_2O(l) \rightarrow 5NO(g) + 3H_3PO_4(aq)$
d. $2Bi(OH)_3(s) + 3Na_2SnO_2(aq) \rightarrow 2Bi(s) + 3Na_2SnO_3(aq) + 3H_2O(l)$

54. a. $16H^+(aq) + 2Cr_2O_7^{2-}(aq) + C_2H_5OH(aq) \rightarrow 4Cr^{3+}(aq) + 2CO_2(g) + 11H_2O(l)$
b. oxidizing agent

55. a. $WO_3(s) + 3H_2(g) \rightarrow W(s) + 3H_2O(g)$
b. H_2
c. H

56. a. oxidized
b. H is the oxidizing agent; Ag is the reducing agent.
c. $2Ag(s) + H_2S(s) \rightarrow Ag_2S(s) + H_2(g)$

ASSESSMENT

Evaluate

Answers

59. **a.** $Ba(ClO_3)_2(s) \rightarrow BaCl_2(s) + 3O_2(g)$
b. $2PbS(s) + 3O_2(g) \rightarrow 2PbO(s) + 2SO_2(g)$

60. $N_2O_4(l) + 2N_2H_4(l) \rightarrow 3N_2(g) + 4H_2O(g)$
Based on oxidation number changes, nitrogen atoms from N_2O_4 gain electrons in forming N_2 and nitrogen atoms from N_2H_4 lose electrons in forming N_2.

61. **a.** reactant, 0; product, 3
b. reactant, 2; product, 2
c. X
d. H

THINK CRITICALLY

62. When one reactant loses electrons another reactant must gain them.

63. $1s^22s^22p^63s^23p^5$ A chlorine atom can "lose" its seven valence electrons or it can gain one electron to fill the last 3*p* orbital.

64. A sodium atom achieves a stable electron configuration by losing its one valence electron, making it a reducing agent. A sodium ion has a stable electron configuration.

65. Double-replacement reactions never involve the transfer of electrons; instead they involve the transfer of ions in aqueous solution.

66. In every redox reaction one species loses one or more electrons and is a reducing agent. Another substance gains one or more electrons and is an oxidizing agent.

67. Iron is easily oxidized, forming rust. Over thousands of years, an iron artifact would most likely have oxidized and crumbled, thereby destroying the artifact.

68. **a.** SO_4^{2-} **b.** H_2O_2 **c.** NO_3^- **d.** $Cr_2O_7^{2-}$ **e.** H_2O

69. Group 1A metals; a reducing agent must give up electrons. Group 1A metals achieve stability by giving up electrons and forming positively charged ions.

70. **a.** $Rb(s) + I_2(s) \rightarrow RbI_2(s)$; oxidizing agent is I
b. $Ba(s) + 2H_2O(l) \rightarrow Ba(OH)_2(aq) + H_2(g)$; oxidizing agent is H
c. $2Al(s) + 3FeSO_4(aq) \rightarrow Al_2(SO_4)_3(aq) + 3Fe(s)$; oxidizing agent is Fe
d. $C_4H_8(g) + 6O_2(g) \rightarrow 4CO_2(g) + 4H_2O(l)$; oxidizing agent is O
e. $Zn(s) + 2HBr(aq) \rightarrow ZnBr_2(aq) + H_2(g)$; oxidizing agent is H
f. $Mg(s) + Br_2(l) \rightarrow MgBr_2(s)$, oxidizing agent is Br

71. Rhenium is oxidized and selenium is reduced, because the bonded electrons would shift toward the more electronegative element, selenium.

72. MnO_4^-, because the manganese is at its highest oxidation state.

* **59.** Write chemical equations for the following redox reactions. Balance each equation using the oxidation-number-change method.
- **a.** Solid barium chlorate decomposes when heated, yielding solid barium chloride and gaseous oxygen.
- **b.** Solid lead(II) sulfide reacts with gaseous oxygen to produce solid lead(II) oxide and gaseous sulfur dioxide.

60. The following unbalanced equation represents a reaction that can occur when dinitrogen tetroxide, N_2O_4, is combined with hydrazine, N_2H_4.

$$N_2O_4(l) + N_2H_4(l) \longrightarrow N_2(g) + H_2O(g)$$

Balance the equation and describe in words the electron transfer that takes place.

61. Examine the following hypothetical redox equation.

$$2X + 3H_2Y \longrightarrow X_2Y_3 + 3H_2$$

- **a.** What is the oxidation number of element X on each side of the equation?
- **b.** What is the oxidation number of element Y on each side of the equation?
- **c.** What is oxidized in this equation?
- **d.** What is reduced in this equation?

Think Critically

62. **Explain** Why must the number of electrons lost equal the number of electrons gained in every redox reaction.

* **63.** **Explain** The highest possible oxidation number that chlorine exhibits in any compound is +7, whereas its most negative oxidation number is −1. Write the electron configuration of chlorine, and explain why these are the limiting oxidation numbers for chlorine.

64. **Explain** Why is a sodium atom a reducing agent but a sodium ion is not?

65. **Explain** Many decomposition, single-replacement, combination, and combustion reactions are also redox reactions. Why is a double-replacement reaction never a redox reaction?

* **66.** **Make Generalizations** Why must every redox reaction have a reducing agent and an oxidizing agent?

67. **Infer** Humankind began to make and use iron tools more than 3000 years ago, but few iron artifacts from ancient times have survived. Explain.

68. **Identify** Which substance in each pair is more likely to be an oxidizing agent?
- **a.** S^{2-} or SO_4^{2-}
- **b.** H_2O or H_2O_2
- **c.** NO_2^- or NO_3^-
- **d.** $Cr_2O_7^{2-}$ or Cr^{3+}
- **e.** H_2 or H_2O

69. **Identify** Which is more likely to be a strong reducing agent, a group 1A metal or a group 7A nonmetal? Explain.

* **70.** **Predict** Predict the product(s) and write the balanced equation for each of these redox reactions. Identify the oxidizing agent in each reaction.
- **a.** rubidium + iodine ⟶
- **b.** barium + water ⟶
- **c.** aluminum + iron(II) sulfate ⟶
- **d.** butene (C_4H_8) + oxygen ⟶
- **e.** zinc + hydrobromic acid ⟶
- **f.** magnesium + bromine ⟶

71. **Explain** The electronegativity of rhenium, Re, is 1.9, and the electronegativity of selenium is 2.4. If rhenium were to react with selenium to form a compound, which element would be oxidized and which element would be reduced? Explain.

72. **Explain** Which of the following ions is most likely to be an oxidizing agent? Explain your choice.

$$MnO_4^-, MnO_4^{2-}, Mn^{+2}$$

Enrichment

* **73.** **Calculate** How many grams of copper are needed to reduce completely the silver ions in 85.0 mL of 0.150*M* $AgNO_3(aq)$ solution?

74. **Calculate** How many milliliters of 0.280*M* $K_2Cr_2O_7(aq)$ solution are needed to oxidize 1.40 g of sulfur? First, balance the equation.

$$K_2Cr_2O_7(aq) + H_2O(l) + S(s) \longrightarrow SO_2(g) + KOH(aq) + Cr_2O_3(s)$$

ENRICHMENT

73. 0.406 g Cu

74. 104 mL $K_2Cr_2O_7$

75. Calculate Carbon monoxide can be removed from the air by passing it over solid diiodine pentoxide.

$$CO(g) + I_2O_5(s) \longrightarrow I_2(s) + CO_2(g)$$

a. Balance the equation.
b. Identify the element being oxidized and the element being reduced.
c. How many grams of carbon monoxide can be removed from the air by 0.55 g of diiodine pentoxide (I_2O_5)?

76. Calculate What is the oxidation number of nitrogen in each of these species?

a. HNO_3 **c.** N_2O_3 **e.** N_2O **g.** NO
b. NH_3 **d.** NO_2^- **f.** NH_4Cl **h.** NO_2

77. Calculate The elements fluorine and oxygen can react to form fluorine monoxide, F_2O. Write the balanced chemical equation for this reaction. Check electronegativity values, and then identify the elements oxidized and reduced.

78. Explain The oxidation number of nitrogen can range from a minimum of −3 to a maximum of +5. Use this information to explain why the nitride ion, N^{3-}, can act only as a reducing agent, and why the nitrate ion, NO_3^-, can act only as an oxidizing agent.

79. Calculate Oxidation-reduction reactions form the basis for chemical analysis by redox titration. Potassium permanganate, a good oxidizing agent, is sometimes used as a titrant because it undergoes a color change as it is reduced.

$$MnO_4^-(aq) \longrightarrow Mn^{2+}(aq)$$
(purple) (colorless)

Write a balanced redox equation for the oxidation of stannous ion to stannic ion in acidic solution using permanganate as the oxidizing reagent.

***80. Describe** There are a number of anions that are commonly used as oxidizing or reducing agents in the laboratory. Balance each of these half reactions. Identify each of the anions as an oxidizing or reducing agent.

a. $Cr_2O_7^{2-}(aq) \rightarrow Cr^{3+}(aq)$ [acidic solution]
b. $S_2O_3^{2-}(aq) \rightarrow SO_4^{2-}(aq)$ [acidic solution]
c. $CrO_4^{2-}(aq) \rightarrow Cr(OH)_3(aq)$ [basic solution]
d. $MnO_4^-(aq) \rightarrow Mn^{2+}(aq)$ [acidic solution]
e. $C_2O_4^{2-}(aq) \rightarrow CO_2(g)$ [acidic solution]
f. $MnO_4^-(aq) \rightarrow MnO_2(s)$ [basic solution]

81. Calculate Combine each of the following pairs of half-reactions into a complete, balanced, ionic redox equation.

a. $Hg^{2+} + 2e^- \longrightarrow Hg$
$Al \longrightarrow Al^{3+} + 3e^-$

b. $MnO_2 + 4H^+ + 2e^- \longrightarrow Mn^{2+} + 2H_2O$
$Fe \longrightarrow Fe^{2+} + 2e^-$

c. $Fe^{3+} + e^- \longrightarrow Fe^{2+}$
$Cd \longrightarrow Cd^{2+} + 2e^-$

Write About Science

82. Explain Silver recovered from shipwrecks may have layers of black tarnish. Research and write a report on how the thick layers of tarnish are removed from the silver artifacts.

83. Connect to the **BIG IDEA** Write a paragraph about five different real-world examples of oxidation-reduction reactions.

CHEMYSTERY

Tarnished Treasure

Gold and silver coins recovered from the same shipwrecked Spanish galleons were exposed to the same elements of the sea. However, the silver coins corrode faster than gold coins because silver is more easily oxidized than gold. Oxidation reactions cause silver coins to corrode, eventually causing their surface to become black and crumbly. Since gold is not as easily oxidized, the gold coins retain their gold color and do not show as many signs of oxidation.

84. Infer Suppose there were two types of coins, one made of magnesium and one made of iron. Which coin would you expect to tarnish faster if they were both exposed to the same conditions?

85. Connect to the **BIG IDEA** Why would it be helpful for shipbuilders to have a knowledge of redox reactions?

Evaluate

CHEMYSTERY **SUMMARIZE** After students have read through the CHEMystery, call on volunteers to summarize why a gold coin would withstand the elements of the sea better than a silver coin. **Ask** Does the oxidation number for silver atoms in the coins increase or decrease while the coins are underwater? *(Because the silver is oxidized, the oxidation number increases.)* **Ask** How could you use gold's and silver's places in the activity series of metals to predict whether they would be easily oxidized? *(Gold is at the bottom of the activity series, which suggests it is very difficult to oxidize. Silver is near the bottom of the list, which suggests it is also hard to oxidize, but easier than gold.)*

Ask Is the black coating on the coins also silver? *(No; it is a silver compound.)* Explain that the black material that forms is silver sulfide, Ag_2S. It forms when silver reacts with hydrogen sulfide, H_2S, releasing hydrogen gas. Have students write a balanced equation for this reaction. *($2Ag + H_2S \rightarrow Ag_2S + H_2$)* **Ask** Based on this equation, how does the oxidation number of silver change during the reaction? *(It changes from 0 to +1.)*

CHEMYSTERY ANSWERS

84. the magnesium coin

85. BIG IDEA Since ships are usually exposed to water and salty conditions, shipbuilders should be aware of which metals are less reactive and therefore less likely to corrode.

Answers

75. a. $5CO + I_2O_5 \rightarrow I_2 + 5CO_2$
b. C is oxidized. I is reduced.
c. 0.22 g CO

76. a. 5 **b.** 3 **c.** 3
d. 3 **e.** 1 **f.** 3
g. 2 **h.** 4

77. $2F_2 + O_2 \rightarrow 2F_2O$; fluorine is reduced; oxygen is oxidized

78. Nitride ion has the minimum oxidation number of -3, therefore it cannot gain additional electrons and be an oxidizing agent. It can lose electrons, however, and be a reducing agent. Nitrogen in the nitrate ion has the maximum oxidation number of +5, therefore it cannot lose additional electrons and enable NO_3^- to be a reducing agent. It can gain electrons, however, and be an oxidizing agent.

79. $2MnO_4^-(aq) + 5Sn^{2+}(aq) + 16H^+(aq) \rightarrow 2Mn^{2+}(aq) + 5Sn^{4+}(aq) + 8H_2O(l)$

80. a. $Cr_2O_7^{2-}(aq) + 14H^+(aq) + 6e^- \rightarrow 2Cr^{3+}(aq) + 7H_2O(l)$
oxidizing agent
b. $S_2O_3^{2-}(aq) + 5H_2O(l) \rightarrow 2SO_4^{2-}(aq) + 10H^+(aq) + 8e^-$
reducing agent
c. $CrO_4^{2-}(aq) + 4H_2O(l) + 3e^- \rightarrow Cr(OH)_3(aq) + 5OH^-(aq)$
oxidizing agent
d. $MnO_4^-(aq) + 8H^+(aq) + 5e^- \rightarrow Mn^{2+}(aq) + 4H_2O(l)$
oxidizing agent
e. $H_2C_2O_4(aq) \rightarrow 2CO_2(g) + 2H^+(aq) + 2e^-$
reducing agent
f. $MnO_4^-(aq) + 4H_2O(l) + 3e^- \rightarrow MnO_2(s) + 5OH^-(aq)$
oxidizing agent

81. a. $3Hg^{2+} + 2Al \rightarrow 3Hg + 2Al^{3+}$
b. $MnO_2 + 4H^+ + Fe \rightarrow Mn^{2+} + 2H_2O + Fe^{2+}$
c. $2Fe^{3+} + Cd \rightarrow 2Fe^{2+} + Cd^{2+}$

WRITE ABOUT SCIENCE

82. Silver is more easily oxidized than is gold. Silver tarnish is mainly silver sulfide. Tarnish can be removed if the silver is placed in a dilute NaOH bath and weak current is passed through the solution.

83. Answers may vary.

CUMULATIVE REVIEW

86. a.

Alkane burned	O_2 used (mol)	CO_2 produced (mol)	H_2O produced (mol)
CH_4	2	1	2
C_2H_6	3.5	2	3
C_3H_8	5	3	4
C_4H_{10}	6.5	4	5
C_5H_{12}	8	5	6
C_6H_{14}	9.5	6	7

b. $C_xH_y + [x + (y/4)]O_2 \longrightarrow xCO_2 + (y/2)H_2O$

87. sublimation

88. 1.8×10^2 kPa

89. suspension; particles settle out of a suspension; not a solution

90. a, c, and d

91. Dilute 110 mL of 6.0*M* HCl to 440 mL total volume.

92. $Ca(NO_3)_2$; boiling point elevation is a colligative property that depends on the number of particles in solution. $Ca(NO_3)_2$ gives three particles per formula unit; LiF gives two particles per formula unit.

93. 0.379M H_3PO_4

94. Solubility $PbBr_2 = 8.1 \times 10^3$M

95. large

96. Test tube B has the NaCl added to it. Due to the common ion effect, the addition of either sulfate ion or barium ion to a saturated solution of $BaSO_4$ will cause the solubility product of $BaSO_4$ to be exceeded and barium sulfate will precipitate as shown in test tubes A and C.

97. **a.** 1.0×10^2M
b. 1.0×10^{11}M
c. 1.6×10^9M

98. 56.3 mL KOH

99. **a.** NH_4^+ and NH_3; H_2O and H_3O^+
b. H_2SO_3 and HSO_3^-; NH_2^- and NH_3
c. HNO_3 and NO_3^-; I and HI

100. **a.** 5.00
b. 10.00
c. 13.00
d. 6.52

Cumulative Review

*86. The complete combustion of hydrocarbons involves the oxidation of both carbon and hydrogen atoms by oxygen. The following table lists the moles of O_2 used, and the moles of CO_2 and moles of H_2O produced, when a series of hydrocarbons called alkanes are burned.

Alkane burned	O_2 used (mol)	CO_2 produced (mol)	H_2O produced (mol)
CH_4	2	1	2
C_2H_6	3.5	2	3
C_3H_8	5	3	4
C_4H_{10}	a. ____	d. ____	g. ____
C_5H_{12}	b. ____	e. ____	h. ____
C_6H_{14}	c. ____	f. ____	i. ____

a. Complete the table.
b. Based on the data, write a balanced generalized equation for the complete oxidation of any alkane. Use the following form, and write the coefficients in terms of *x* and *y*:

$$C_xH_y + \_\_ O_2 \longrightarrow \_\_ CO_2 + \_\_ H_2O$$

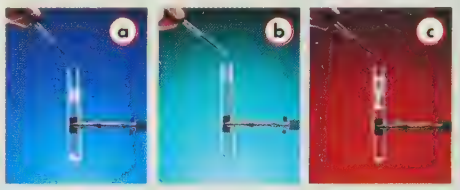
87. Name a change of state that does not involve a liquid.

*88. A gas cylinder has a volume of 6.8 L and is filled with 13.8 g of N_2. Calculate the pressure of N_2 at 25°C.

89. A particular paint must be stirred before using. Is the stirred paint a solution or a suspension? Explain.

90. Which of these are nonelectrolytes?
a. $S(s)$ **c.** $SiO_2(s)$
b. $NH_4Cl(aq)$ **d.** $F_2(g)$

*91. How would you make 440 mL of 1.5*M* HCl solution from a stock solution of 6.0*M* HCl?



92. One mole of LiF and $Ca(NO_3)_2$ are each dissolved in 1.0 L of water. Which solution has the higher boiling point? Explain.

93. What is the molarity of the solution prepared by dissolving 46.4 g H_3PO_4 in enough water to make 1.25 L of solution?

*94. The K_{sp} of lead(II) bromide ($PbBr_2$) at 25°C is 2.1×10^{-6}. What is the solubility of $PbBr_2$ (in mol/L) at this temperature?

95. A reaction goes essentially to completion. Do you expect the value of *K* to be large or small?

96. Bottles containing 0.1*M* solutions of Na_2SO_4, $BaCl_2$, and NaCl have had their labels accidentally switched. To discover which bottle contains the NaCl, you place a clear saturated solution of $BaSO_4$ ($K_{sp} = 1.1 \times 10^{-10}$) into three test tubes. To each test tube you add a few drops of each mislabeled solution. The results are shown below. To which tube was NaCl added? Explain.

97. What is the hydrogen-ion concentration of solutions with the following pH?
a. 2.00 **b.** 11.00 **c.** 8.80

98. How many milliliters of a 4.00*M* KOH solution are needed to neutralize 45.0 mL of 2.50*M* H_2SO_4 solution?

99. Identify the conjugate acid-base pairs in each equation.
a. $NH_4^+(aq) + H_2O(l) \longrightarrow NH_3(aq) + H_3O^+(aq)$
b. $H_2SO_3(aq) + NH_2^-(aq) \longrightarrow HSO_3^-(aq) + NH_3(aq)$
c. $HNO_3(aq) + I^-(aq) \longrightarrow HI(aq) + NO_3^-(aq)$

*100. Calculate the pH of solutions with the following hydrogen-ion or hydroxide-ion concentrations. Classify each as acidic, basic, or neutral.
a. $[H^+] = 0.000\,010M$
b. $[OH^-] = 1.0 \times 10^{-4}M$
c. $[OH^-] = 1.0 \times 10^{-1}M$
d. $[H^+] = 3.0 \times 10^{-7}M$

Standardized Test Prep for Indiana

Standard: C.4.6

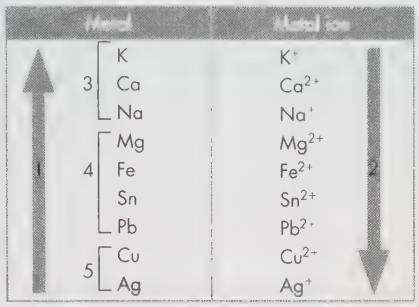
Select the choice that best answers each question or completes each statement.

1. Which of these processes is not an oxidation?
   (A) a decrease in oxidation number
   (B) a complete loss of electrons
   (C) a gain of oxygen
   (D) a loss of hydrogen by a covalent molecule

2. In which of these pairs of nitrogen-containing ions and compounds is the oxidation number of nitrogen in the ion higher than in the nitrogen compound?
   I. N_2H_4 and NH_4^+
   II. NO_3^- and N_2O_4
   III. N_2O and NO_2^-
   (A) I only (D) II and III only
   (B) I and II only (E) I, II, and III
   (C) I and III only

3. Identify the elements oxidized and reduced in this reaction.
   $2ClO^- + H_2 + 2e^- \longrightarrow 2Cl^- + 2OH^-$
   (A) Cl is oxidized; H is reduced
   (B) H is oxidized; Cl is reduced
   (C) Cl is oxidized; O is reduced
   (D) O is oxidized; Cl is reduced

4. Which of these half-reactions represents a reduction?
   I. $Fe^{2+} \longrightarrow Fe^{3+}$
   II. $Cr_2O_7^{2-} \longrightarrow Cr^{3+}$
   III. $MnO_4^- \longrightarrow Mn^{2-}$
   (A) I and II only (C) I and III only
   (B) II and III only (D) I, II, and III



5. Which of these general types of reactions is not a redox reaction?
   (A) single replacement (C) combustion
   (B) double replacement (D) combination

6. What is the reducing agent in this reaction?
   $MnO_4^- + SO_2 \longrightarrow Mn^{2+} + SO_4^{2-}$
   (A) SO_2 (C) Mn^{2+}
   (B) SO_4^{2-} (D) MnO_4^-

Tips for Success

Interpreting Data Tables To interpret the content in a table, start by reading the title (if there is one). Then, read the headings. Try to figure out the relationship between the different columns and rows of information. Ask yourself: *What information is related in the table? How are the relationships represented?*

Use the table to answer Questions 7–9.

7. Which arrow indicates increasing ease of oxidation? Of reduction?

8. Which numbered group of metals are the strongest reducing agents? Which numbered group of metals are the most difficult to oxidize?

9. Which is a stronger oxidizing agent, Na or Fe?

Use this diagram to answer Questions 10 and 11. It shows the formation of an ion from an atom.

10. Does the diagram represent oxidation or reduction? Does the oxidation number increase or decrease when the ion forms?

11. Draw a diagram showing the formation of a sulfide ion from a sulfur atom. Make the relative sizes of the atom and ion realistic. Does your drawing represent an oxidation or a reduction?

Materials List

For the Student

Quick Lab, p 750
- 9-V battery, sodium sulfate solution
- copper penny
- nickel coin
- iron nail
- filter paper
- aluminum foil
- reaction surface

Small-Scale Lab, p 752
- reaction surface
- electrolysis device
- droppers
- 0.2M Na_2SO_4
- 0.1M KI
- 0.2M $CuSO_4$
- 0.04% BTB
- 1.0M NaCl
- 0.2M KBr
- liquid starch

For the Teacher

Teacher Demo, p 730
- 200 mL of 0.1M silver nitrate
- 250-mL beaker
- glass stirring rod
- strip of polished copper metal

Teacher Demo, p 733
- 2 strips of lead
- wooden rod
- 2 connecting wires
- 250-mL beaker
- dilute sulfuric acid
- 6-V DC power supply
- doorbell

Teacher Demo, p 732
- dry cell
- voltmeter
- 2 wire leads
- zinc electrode
- carbon electrode
- manganese dioxide/ ammonium chloride paste

Teacher Demo, p 739
- 2 pennies
- metal wires from twist ties
- table salt
- paper towel

Teacher Demo, p 747
- Hoffman apparatus or apparatus constructed using iron nails as electrodes
- 2 test tubes
- 6M NaOH
- 250- or 500-mL beaker
- 2 insulated wire leads

20.2 Virtual Chem Lab 30: Redox Titrations: Determination of Iron

CHAPTER 21

21 Electrochemistry

INSIDE:

- **21.1** Electrochemical Cells
- **21.2** Half-Cells and Cell Potentials
- **21.3** Electrolytic Cells

PearsonChem.com

An electrochemical process was used to produce the shiny chrome finish on this car.

What's Online

CHEM TUTOR Students access guided, step-by-step tutorials for solving various electrochemistry problems.

PROBLEM SETS Students can practice key problem-solving skills in an online problem set.

MATH HELP Identify the students that struggle with math by assigning an online math skills diagnostic test. These students can then improve and practice math skills using the MathXL tutorial system.

VIRTUAL LAB Students go on an animated virtual lab tour in which electrochemical reactions are studied in a simulated laboratory environment."

KINETIC ART Students watch animations of selected figures from the chapter, and then answer questions that check for understanding.

CONCEPTS IN ACTION "Students watch an overview of a key chapter concept using real-world contexts and concrete examples and analogies. Each activity includes an interactive animation followed by analysis questions.

IN ACADEMIC STANDARDS for SCIENCE

Nature of Science

- Develop explanations based on reproducible data and observations gathered during laboratory investigations.

Standard 7: Solutions

C.7.2 Explain how changes in temperature, surface area, and pressure affect solubility.

C.7.6 Explain how the rate of a reaction is qualitatively affected by changes in concentration, temperature, surface area, and the use of a catalyst.

C.7.7 Describe dynamic equilibrium in terms of changes in amounts of reactants and products.

C.7.8 Write equilibrium expressions for reversible reactions.

Focus on ELL

1 CONTENT AND LANGUAGE Begin the class by writing *Electrochemistry* on the board and pronouncing it slowly. Have students determine the meaning of the word from its prefix. Then, present a complete list of the vocabulary terms in this chapter. Have students examine how these terms are related to the chapter content.

BEGINNING: LOW/HIGH Create illustrations to represent the terms. If literate, create a native language definition.

INTERMEDIATE: LOW/HIGH Provide students with sentences in which key words have been replaced with blanks. Have students complete the blanks with words from a given word bank as they read through the chapter.

ADVANCED: LOW/HIGH Challenge students to create their own sentences in which key words have been replaced with blanks. Have students trade papers with a partner to help them review lesson terminology.

BIGIDEA

MATTER AND ENERGY

Essential Questions:

1. *How is energy produced in an electrochemical process?*
2. *How can energy be used to drive an electrochemical process?*

CHEMYSTERY

Trash or Treasure?

Maria and her friend decided to spend the Saturday browsing a local flea market. At one vendor's display, Maria spotted a beautiful, shiny gold ring. The vendor told Maria that the ring was an antique from the 1800s and made from solid gold. Enamored by the ring, Maria purchased it and placed it on her finger.

Several weeks later, while taking off the ring, Maria noticed that the ring was discolored in many places. It almost looked like the gold was peeling off the ring. Maria was disturbed because the ring was expensive, and she believed that it was a valuable antique. She decided to take the ring to a jeweler to see if it could be polished and restored to its original gold color. However, Maria became upset when the jeweler revealed the truth about her "gold" ring.

▶ Connect to the BIGIDEA As you read about electrochemical processes, think about how a ring could be made to look like it was made out of pure gold when it was not.

Introduce the Chapter

CONNECTIONS TO REDOX REACTIONS In Chapter 20, students learned how oxidation-reduction reactions can change materials. Use these activities to introduce students to the connection between redox reactions and electrochemistry.

Activity 1 *You will need a simple circuit composed of wire, a dry cell battery, and a bulb.* Have a student connect the wire to complete the circuit. Point out that an electrical current is needed to light the bulb. Explain that charge moves through the battery by a redox reaction. Tell students that they will learn about electrical applications of redox reactions in this chapter.

Activity 2 *You will need rusted nails, a nut or bolt electroplated with zinc, and a shiny chrome material which has scratches with rust.* Pass the materials around for students to observe. Point out that the coated metal did not rust. Ask How do you think the coating was applied to the metals? *(Students may think it was painted on.)* Explain that electrical energy was used to cause a redox reaction that coated the metal.

UbD

Understanding by Design

Students are building toward understanding electrochemistry using the relationship between matter and energy.

PERFORMANCE GOALS At the end of Chapter 21, students will be able to answer the essential questions by applying their knowledge of electrochemistry. Students will also be able to calculate standard cell potentials.

ESSENTIAL QUESTIONS Read the essential questions aloud. **Ask** What two main types of energy do you think are involved in an electrochemical process? *(electrical and chemical)* **Ask** Why would electrical energy be involved in redox reactions? *(It involves the flow of electrons.)*

BIGIDEA Use the photo of the chrome on a car to help students connect to the concepts they will learn in this chapter. Activate prior knowledge by asking students to name chrome items familiar to them. **Ask** Is chrome an element? *(No. It is an alloy, or mixture of metals, containing chromium that is deposited onto a surface.)* **Ask** How do you think they get the chrome onto the surface? *(using a redox reaction)*

CHEMYSTERY Have students read over the CHEMystery. Connect the CHEMystery to the Big Idea of Matter and Energy by reminding students that matter can undergo both physical changes and chemical changes. Encourage students to think about whether a physical change or chemical change might have been used to make Maria's ring look like solid gold. Then, have them predict what the change was. As a hint, suggest that they consider how electrical energy could have been used to change the ring.

LESSON 21.1

Key Objectives

21.1.1 IDENTIFY the type of chemical reaction that is involved in all electrochemical processes.

21.1.2 DESCRIBE how a voltaic cell produces electrical energy.

21.1.3 IDENTIFY the current applications that use electrochemical processes to produce electrical energy.

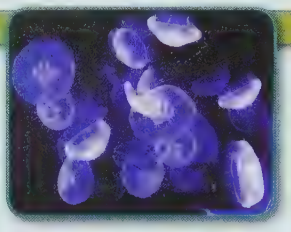
Additional Resources

Reading and Study Workbook, Lesson 21.1

Available Online or on Digital Media:

- Teaching Resources, Lesson 21.1 Review
- Laboratory Manual, Lab 47
- Small-Scale Chemistry Laboratory Manual, Lab 36

PearsonChem.com



Engage

CHEMISTRY & YOU Have students read the opening paragraph. **Ask** What have you learned that shows that energy can be released in the form of light? *(When electrons drop from higher to lower energy levels in an atom they emit energy in the form of light.)*

Activate Prior Knowledge

Review the concepts of reversible reactions and spontaneous and nonspontaneous reactions that were introduced in Chapter 18. **Ask** If a reaction releases free energy, is the reaction spontaneous or nonspontaneous? *(spontaneous)*

21.1 Electrochemical Cells

CHEMISTRY & YOU

Q: *Why do some kinds of jellyfish glow?* On a summer evening, fireflies glow to attract their mates. In the ocean depths, angelfish emit light to attract prey. Luminous shrimp, squid, jellyfish, and even bacteria also exist. These organisms, and others, are able to give off energy in the form of light as a result of redox reactions.

Key Questions

What type of chemical reaction is involved in all electrochemical processes?

How does a voltaic cell produce electrical energy?

What current applications use electrochemical processes to produce electrical energy?

Vocabulary

- electrochemical process
- electrochemical cell
- voltaic cell • half-cell
- salt bridge • electrode
- anode • cathode • dry cell
- battery • fuel cell

Electrochemical Processes

What type of chemical reaction is involved in all electrochemical processes?

Chemical processes can either release energy or absorb energy. The energy can sometimes be in the form of electricity. An **electrochemical process** is any conversion between chemical energy and electrical energy. **All electrochemical processes involve redox reactions.** Electrochemical processes have many applications in the home as well as in industry. Flashlight and automobile batteries are familiar examples of devices used to generate electricity. The manufacture of sodium and aluminum metals and the silver-plating of tableware involve the use of electricity. Biological systems also use electrochemistry to carry nerve impulses.

Redox Reactions and the Activity Series When a strip of zinc metal is dipped into an aqueous solution of blue copper(II) sulfate, the zinc becomes copper-plated, as shown in Figure 21.1. The net ionic equation involves only zinc and copper.

$$Zn(s) + Cu^{2+}(aq) \longrightarrow Zn^{2+}(aq) + Cu(s)$$

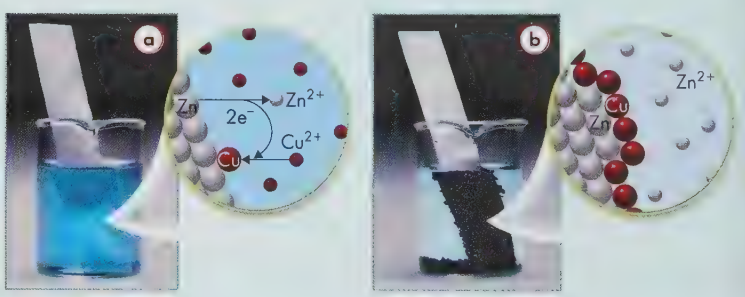


Figure 21.1
Redox Reaction
Zinc metal oxidizes spontaneously in a copper-ion solution. **a.** A zinc strip is immersed in a solution of copper(II) sulfate. **b.** As the copper plates out onto the zinc, the blue copper(II) sulfate solution is replaced by a colorless solution of zinc sulfate. The copper appears black because it is in a finely divided state.

Focus on ELL

1 CONTENT AND LANGUAGE Draw students' attention to the words *anode* and *cathode*. Explain that the word cathode comes from the Greek *kathodos* meaning "way down" and that the word anode comes from the Greek *anodos* meaning "way up." Thus the two words, cathode and anode, are opposites. Write the symbols – and + next to words.

2 FRONTLOAD THE LESSON Ask students to recall what they know about electricity, electrical current, and circuits. Then, have students examine Figure 21.3 and identify features that the voltaic cell shares with an electrical circuit. Explain that, in this lesson, they will learn how an electrical current can be generated using chemicals.

3 COMPREHENSIBLE INPUT Help students visualize a dry cell as a classic aqueous voltaic cell by drawing Figure 21.3 on the board. Have students use a think-aloud strategy to determine which of the dry cell components in Figure 21.4 are equivalent to the aqueous cell components as you write the labels on the drawing.

Interpret Data

Activity Series of Metals

	Element	Oxidation half-reaction
Most active and most easily oxidized	Lithium	$Li(s) \longrightarrow Li^+(aq) + e^-$
	Potassium	$K(s) \longrightarrow K^+(aq) + e^-$
	Barium	$Ba(s) \longrightarrow Ba^{2+}(aq) + 2e^-$
	Calcium	$Ca(s) \longrightarrow Ca^{2+}(aq) + 2e^-$
	Sodium	$Na(s) \longrightarrow Na^+(aq) + e$
	Magnesium	$Mg(s) \longrightarrow Mg^{2+}(aq) + 2e^-$
	Aluminum	$Al(s) \longrightarrow Al^{3+}(aq) + 3e^-$
	Zinc	$Zn(s) \longrightarrow Zn^{2+}(aq) + 2e^-$
	Iron	$Fe(s) \longrightarrow Fe^{2+}(aq) + 2e$
	Nickel	$Ni(s) \longrightarrow Ni^{2+}(aq) + 2e$
	Tin	$Sn(s) \longrightarrow Sn^{2+}(aq) + 2e^-$
	Lead	$Pb(s) \longrightarrow Pb^{2+}(aq) + 2e^-$
	Hydrogen*	$H_2(g) \longrightarrow 2H^+(aq) + 2e^-$
	Copper	$Cu(s) \longrightarrow Cu^{2+}(aq) + 2e^-$
	Silver	$Ag(s) \longrightarrow Ag^+(aq) + e$
	Mercury	$Hg(s) \longrightarrow Hg^{2+}(aq) + 2e$
Least active and least easily oxidized	Gold	$Au(s) \longrightarrow Au^{3+}(aq) + 3e^-$

Decreasing activity

*Hydrogen is included for reference purposes.

Table 21.1 The half-reaction for the oxidation of each metal is shown.

a. Read Tables What is the half-reaction for the oxidation of nickel?

b. Compare Which metal is more readily oxidized, lead or magnesium?

c. Relate Cause and Effect What will happen if a strip of copper is dipped in a solution of silver nitrate? If a reaction occurs, write the half-reactions.

Remember: The more active metal will be oxidized; the less active metal will be reduced.

Electrons are transferred from zinc atoms to copper ions. This is a spontaneous redox reaction. Zinc atoms lose electrons as they are oxidized to zinc ions, while copper ions in solution gain the electrons lost by the zinc. The copper ions are reduced to copper atoms and are deposited as metallic copper. As the copper ions in solution are gradually replaced by zinc ions, the blue color of the solution fades. The balanced half-reactions for this redox reaction can be written as follows:

$$\text{Oxidation:} \quad Zn(s) \longrightarrow Zn^{2+}(aq) + 2e^-$$

$$\text{Reduction:} \quad Cu^{2+}(aq) + 2e^- \longrightarrow Cu(s)$$

In the activity series of metals in Table 21.1, zinc is above copper on the list. For any two metals in an activity series, the more active metal is the more readily oxidized. Zinc is more readily oxidized than copper. When zinc is dipped into a copper(II) sulfate solution, zinc becomes plated with copper. In contrast, when a copper strip is dipped into a solution of zinc sulfate, the copper does not spontaneously become plated with zinc. This is because copper metal is not oxidized by zinc ions.

Differentiated Instruction

L3 ADVANCED STUDENTS Challenge students to research the electrochemical nature of the nervous system. Students may want to focus on different aspects of the system and combine their findings into a visual display and/or oral report. Possible areas to be addressed include the role of sodium and potassium ions, how signals are transmitted across synapses, what an EEG measures, and the value of squid for nervous system research.

L1 STRUGGLING STUDENTS Have students think about the half-reactions in Table 21.1 in terms of where the element is located in the periodic table. Remind them of what they learned in Chapter 6 about periodic trends in chemical properties. Point out that the elements on the left side of the periodic table are more easily oxidized (lose electrons) than the elements on the right side of the periodic table. Explain that Group 1A and 2A metals, listed at the top of the activity series, are some of the most reactive elements in nature.

Foundations for Reading

BUILD VOCABULARY Have students create a concept map from the vocabulary terms for the lesson. Encourage students to include drawings or symbols to enhance the descriptions used to explain the connections made in the map.

READING STRATEGY Show students how to make an outline as they read this section. Have them use the red headings as their main entries and the blue headings as secondary entries. Ask them to include, under each heading, a sentence summarizing the important idea.

Explain

Electrochemical Processes

USE VISUALS Direct students to Figure 21.1. **Ask** What is the color of the copper (II) sulfate solution in Figure 21.1a? *(blue)* Is the color different in Figure 21.1b? *(It's still blue but lighter in color.)* What is the significance of the lighter color? *(Blue copper (II) ions have been removed from the solution and changed into the copper atoms on the zinc.)* Next, direct students' attention to Table 21.1. **Ask** In regard to what you have learned previously, what does *most active* mean? *(The ionization energy needed for an atom to lose an electron is less, therefore it is more likely to occur.)* Have students locate Zn and Cu in the table. **Ask** Look back at the net ionic equation for the copper-plating reaction. Which species was oxidized in that reaction? *(Zn)* **Ask** If a gold bar was placed in the $CuSO_4$ solution, would you expect it to become copper-plated? Why? *(No, it is lower on the activity series than copper, so it would be more likely to be reduced than oxidized.)*

APPLY CONCEPTS Explain that redox reactions make it possible for energy interconversion between electrical energy and chemical energy. Review oxidation and reduction half-cell reactions and stress that the electrons must be balanced. Show how these reactions are combined to form the net ionic equation for an electrochemical process. Point out that the net equation summarizes the transfer of electrons from the species being oxidized to the species being reduced.

Answers

INTERPRET DATA

a. $Ni(s) \rightarrow Ni^{2+}(aq) + 2e^-$

b. magnesium

c. The copper becomes plated with silver.
$Cu(s) \rightarrow Cu^{2+}(aq) + 2e^-$
$Ag^+(aq) + e^- \rightarrow Ag(s)$

Explore

Teacher Demo

PURPOSE Students will observe a redox reaction.

MATERIALS 200 mL 0.1*M* silver nitrate ($AgNO_3$) in a 250 mL beaker, glass stirring rod, strip of polished copper metal

SAFETY Wear gloves, apron, and safety goggles.

PROCEDURE Put a glass stirring rod across the top of the beaker and suspend a polished copper strip from the rod so that the strip dips into the $AgNO_3$ solution. The metal surface will darken and appear "fuzzy" as silver metal is deposited. Over time, a layer of silver will form on the copper. **Ask** What is the significance of the blue color of the solution? *(Blue copper(II) ions are being produced.)* Write on the board the net reaction for the electrochemical process:

$2Ag^+(aq) + Cu(s) \rightarrow 2Ag(s) + Cu^{2+}(aq)$

Point out that the reaction involves a transfer of electrons from copper atoms to silver ions. **Ask** What was oxidized? What was reduced? *(Copper was oxidized; silver ions were reduced.)* Combine liquid wastes and add a 50% molar excess of NaCl. Filter or decant and dry the AgCl residue. Put in a plastic container and bury in an approved landfill. Flush the filtrate down the drain with excess water.

EXPECTED OUTCOME Silver crystals form on the copper wire. The solution turns blue because of dissolved copper(II) ions.

Q: *Jellyfish and other creatures that glow contain compounds that undergo redox reactions. What do these reactions have in common with redox reactions that occur in electrochemical cells?*

Electrochemical Cells When a zinc strip is dipped into a copper(II) sulfate solution, electrons are transferred from zinc atoms to copper ions. This flow of electrons is an electric current. If a redox reaction is to be used as a source of electrical energy, the two half-reactions must be physically separated. In the case of the zinc-metal–copper-ion reaction, the electrons released by the zinc atoms must pass through an external circuit to reach the copper ions if useful electrical energy is to be produced. In that situation, the system serves as an electrochemical cell. Alternatively, an electric current can be used to produce a chemical change. That system also serves as an electrochemical cell. Any device that converts chemical energy into electrical energy or electrical energy into chemical energy is an **electrochemical cell.** Redox reactions occur in all electrochemical cells.

Voltaic Cells

How does a voltaic cell produce electrical energy?

In 1800, the Italian physicist Alessandro Volta built the first electrochemical cell that could be used to generate a direct electric current (DC). Named after its inventor, a **voltaic cell** is an electrochemical cell used to convert chemical energy into electrical energy. **Electrical energy is produced in a voltaic cell by a spontaneous redox reaction within the cell.** You can find voltaic cells everywhere. They power your flashlight and your mp3 player, as shown in Figure 21.2.

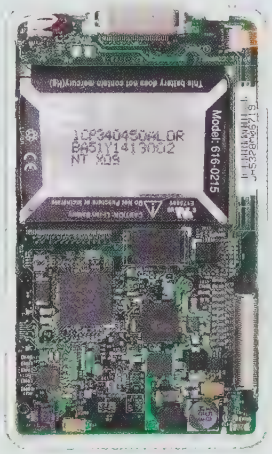

Figure 21.2 Voltaic Cell
A voltaic cell powers this mp3 player.
Predict *What other items contain voltaic cells?*

Constructing a Voltaic Cell A voltaic cell consists of two half-cells. A **half-cell** is one part of a voltaic cell in which either oxidation or reduction occurs. A typical half-cell consists of a piece of metal immersed in a solution of its ions. Figure 21.3 on the following page shows a voltaic cell that makes use of the zinc–copper reaction. In this cell, one half-cell is a zinc strip immersed in a solution of zinc sulfate. The other half-cell is a copper strip immersed in a solution of copper(II) sulfate.

The half-cells are connected by a **salt bridge,** which is a tube containing a strong electrolyte, often potassium sulfate (K_2SO_4). Salt bridges also contain agar, a gelatinous substance. A porous plate may be used instead of a salt bridge. The salt bridge or porous plate allows ions to pass from one half-cell to the other but prevents the solutions from mixing completely. A wire carries the electrons in the external circuit from the zinc strip to the copper strip. A voltmeter or light bulb can be connected in the circuit. The driving force of such a voltaic cell is the spontaneous redox reaction between zinc metal and copper ions in solution.

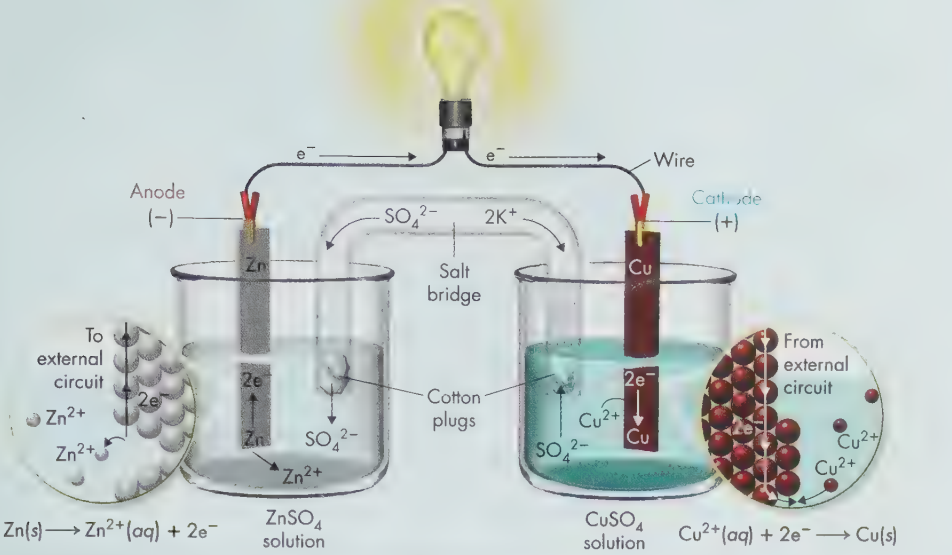
The zinc and copper strips in this voltaic cell serve as the electrodes. An **electrode** is a conductor in a circuit that carries electrons to or from a substance other than a metal. The reaction at the electrode determines whether the electrode is labeled as an anode or a cathode. The electrode at which oxidation occurs is called the **anode.** Electrons are produced at the anode. Therefore, the anode is labeled the negative electrode in a voltaic cell. The electrode at which reduction occurs is called the **cathode.** Electrons are consumed at the cathode in a voltaic cell. As a result, the cathode is labeled the positive electrode. Neither electrode is actually charged, however. All parts of the voltaic cell remain balanced in terms of charge at all times. The moving electrons balance any charge that might build up as oxidation and reduction occur.

UbD Check for Understanding

What type of chemical reaction is involved in all electrochemical processes?

Assess students' understanding that electrochemical processes are redox reactions by asking the following questions. **Ask** What is transferred between ions in a redox reaction? *(electrons)* **Ask** What is transferred between ions in an electrochemical reaction? *(electrons)* **Ask** What happens to the ion that gives up electrons in an electrochemical reaction? *(It is oxidized.)* **Ask** What happens to the ion that receives electrons in an electrochemical reaction? *(It is reduced.)*

ADJUST INSTRUCTION If students are confusing oxidation and reduction, have them reread Lesson 20.1 on the Meaning of Oxidation-Reduction as well as the text following the section on Electrochemical Processes in Lesson 21.1. Then, write the chemical reaction shown at the bottom of the previous page on the board and diagram the movement of electrons between the reactants and products to reinforce the concept that this electrochemical reaction is an oxidation-reduction reaction.



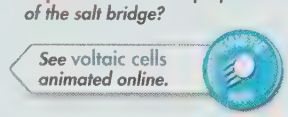


Figure 21.3 Zinc–Copper Voltaic Cell
In this voltaic cell, the electrons generated from the oxidation of Zn to Zn^{2+} flow through the external circuit (the wire) into the copper strip. These electrons reduce the surrounding Cu^{2+} to Cu. To maintain neutrality in the electrolytes, anions flow through the salt bridge.
Explain ***What is the purpose of the salt bridge?***

How a Voltaic Cell Works The electrochemical process that occurs in a zinc–copper voltaic cell can best be described in a number of steps. These steps actually occur at the same time.

Step 1 Electrons are produced at the zinc strip according to the oxidation half-reaction:

$$Zn(s) \longrightarrow Zn^{2+}(aq) + 2e^-$$

Zinc is oxidized at the zinc strip, so the zinc strip is the anode, or negative electrode, in the voltaic cell.

Step 2 The electrons leave the zinc anode and pass through the external circuit to the copper strip. (If a bulb is in the circuit, the electron flow will cause it to light. If a voltmeter is present, it will indicate a voltage.)

Step 3 Electrons enter the copper strip and interact with copper ions in solution. There, the following reduction half-reaction occurs:

$$Cu^{2+}(aq) + 2e^- \longrightarrow Cu(s)$$

Copper ions are reduced at the copper strip, so the copper strip is the cathode, or positive electrode, in the voltaic cell.

Step 4 To complete the circuit, both positive and negative ions move through the aqueous solutions via the salt bridge. The two half-reactions can be summed to show the overall cell reaction. Note that the electrons must cancel.

$$Zn(s) \longrightarrow Zn^{2+}(aq) + 2e^-$$
$$Cu^{2+}(aq) + 2e^- \longrightarrow Cu(s)$$
$$\overline{Zn(s) + Cu^{2+}(aq) \longrightarrow Zn^{2+}(aq) + Cu(s)}$$

Differentiated Instruction

L1 LESS PROFICIENT READERS Students may have difficulty remembering that oxidation occurs at the anode of a voltaic cell and reduction occurs at the cathode. Tell them that consonants go together and vowels go together. Both cathode and reduction begin with consonants and anode and oxidation start with vowels.

ELL ENGLISH LANGUAGE LEARNERS Clarify students' understanding of the word *cell* as it relates to this lesson. Make sure they are not looking for a living cell as they might have learned from biology class. Stress that an electrochemical cell is a chemical system that generates electrical energy.

L1 SPECIAL NEEDS STUDENTS For developmentally delayed students, provide simple DC devices, such as flashlights, cell phones, walkie-talkies, etc. Have them determine how the battery must be inserted in order for the object to power up. Tell students to pay particular attention to the markings on the batteries and the battery compartments.

Explain

Voltaic Cells

USE VISUALS Direct students' attention to Figure 21.3. Explain that voltaic cells can be used as sources of electrical energy because the two half-reactions are physically separated. The reaction in the illustration could take place in a single beaker, but it would not be possible to produce a stream of electrons. **Ask** At which electrode does oxidation (loss of electrons) take place? *(Oxidation occurs at the anode (negative electrode).)* **Ask** Where does reduction (gain of electrons) take place? *(Reduction occurs at the cathode (positive electrode).)* **Ask** What path do the electrons given up by zinc follow? *(They go through the wire and the electric light to the copper electrode.)* **Ask** What happens to the electrons at the copper electrode? *(They reduce copper ions to copper.)*

APPLY CONCEPTS In discussing the need for a salt bridge in the Zn/Cu voltaic cell, explain that as zinc is oxidized at the anode, Zn^{2+} ions enter the solution. Explain that they have no negative ions to balance their charges, so a positive charge tends to build up around the anode. Similarly, point out that at the cathode, Cu^{2+} ions are reduced to Cu and taken out of the solution, leaving behind unbalanced negative ions. Thus, a negative charge tends to develop around the cathode. Convey that the salt bridge allows negative ions, such as SO_4^{2-}, to be drawn to the anode compartment to balance the growing positive charge. Likewise, positive ions, such as K^+, are drawn from the salt bridge to balance the growing negative charge at the cathode.

Answers

FIGURE 21.2 Most handheld electronic devices are powered by voltaic cells, including calculators and flashlights.

FIGURE 21.3 to prevent significant build-up of charges at the electrodes

Explore

Using Voltaic Cells as Energy Sources

Teacher Demo

PURPOSE Students will observe the construction of a dry cell.

MATERIALS dry cell, voltmeter, 2 wire leads, zinc electrode, carbon electrode, manganese dioxide/ammonium chloride paste (Prepare the paste by adding saturated $NH_4Cl(aq)$ to powdered MnO_2 until thick.)

PROCEDURE Before class, cut through a dry cell with a hacksaw from the top down on the right side of the central carbon electrode. In class, have students identify the three parts of the cell. *(The graphite rod is the cathode, the zinc container is the anode, and the manganese dioxide/ammonium chloride paste is the electrolyte.)* Construct a dry cell by placing a zinc electrode and a carbon electrode into a manganese dioxide/ammonium chloride paste. Connect the cell to a voltmeter and measure the potential.

EXPECTED OUTCOME Students should be able to identify the anode, cathode, and electrolyte in each cell.

Explain

APPLY CONCEPTS Explain to students that, by itself, a dry cell does not provide a complete circuit, that is, electrons cannot flow from the anode to the cathode. When devices using dry cells are turned on, an external circuit is completed, allowing the flow of electrons from the anode to the cathode.

USE VISUALS Direct students to Figure 21.4. Ask students to describe the difference between the common dry cell and the alkaline battery. *(In the alkaline dry cell, the electrolyte is a basic KOH paste, thus the distinction of this dry cell as* alkaline.*)*

Representing Electrochemical Cells You can represent the zinc–copper voltaic cell by using the following shorthand form.

$$Zn(s) \mid ZnSO_4(aq) \parallel CuSO_4(aq) \mid Cu(s)$$

The single vertical lines indicate boundaries of phases that are in contact. The zinc strip, $Zn(s)$, and the zinc sulfate solution, $ZnSO_4(aq)$, for example, are separate phases in physical contact. The double vertical lines represent the salt bridge or porous partition that separates the anode compartment from the cathode compartment. The half-cell that undergoes oxidation (the anode) is written first, to the left of the double vertical lines.

Using Voltaic Cells as Energy Sources

What current applications use electrochemical processes to produce electrical energy?

Although the zinc–copper voltaic cell is of historical importance, it is no longer used commercially. **Current applications that use electrochemical processes to produce electrical energy include dry cells, lead storage batteries, and fuel cells.**

Dry Cells When a compact, portable electrical energy source is required, a dry cell is usually chosen. A **dry cell** is a voltaic cell in which the electrolyte is a paste. In one type of dry cell, a zinc container is filled with a thick, moist electrolyte paste of manganese(IV) oxide (MnO_2), zinc chloride ($ZnCl_2$), ammonium chloride (NH_4Cl), and water (H_2O). As shown in Figure 21.4a, a graphite rod is embedded in the paste. The zinc container is the anode, and the graphite rod is the cathode. The thick paste and its surrounding paper liner prevent the contents of the cell from freely mixing, so a salt bridge is not needed. The half-reactions for this cell are shown below.

Learn about chemical energy sources online.

Oxidation: $Zn(s) \longrightarrow Zn^{2+}(aq) + 2e^-$ (at anode)

Reduction: $2MnO_2(s) + 2NH_4^+(aq) + 2e^- \longrightarrow Mn_2O_3(s) + 2NH_3(aq) + H_2O(l)$ (at cathode)

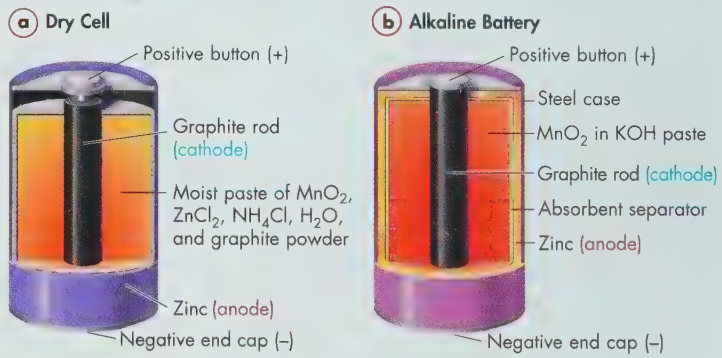

Figure 21.4 Dry Cells Both dry cells and alkaline batteries are single electrochemical cells that produce about 1.5 V. **a.** The dry cell is inexpensive, has a short shelf life, and suffers from voltage drop when in use. **b.** The alkaline battery has a longer shelf life and does not suffer from voltage drop.

Apply Concepts *What is oxidized in these cells and what is reduced?*

UbD

Check for Understanding

How does a voltaic cell produce electrical energy?

Assess students' understanding of how a voltaic cell produces electrical energy by listing the following vocabulary terms on the board: *voltaic cell*, *half-cell*, *salt bridge*, *electrode*, *anode*, and *cathode*. Then, have students write a brief paragraph using the vocabulary terms that answers the key question.

ADJUST INSTRUCTION If students are having difficulty with this concept, have students reread the Voltaic Cells section. Then, draw or project Figure 21.3 on the board. Read each numbered step in the section How A Voltaic Cell Works, and have students indicate where on the figure that step takes place. Provide students with an opportunity to revise their paragraphs.

In an ordinary dry cell, the graphite rod serves only as a conductor and does not undergo reduction, even though it is the cathode. The manganese in MnO_2 is the species that is actually reduced. The electrical potential of this cell starts out at 1.5 V but decreases steadily during use to about 0.8 V. Dry cells of this type are not rechargeable because the cathode reaction is not reversible.

The alkaline battery, shown in Figure 21.4b on the previous page, is an improved dry cell. In the alkaline battery, the reactions are similar to those in the common dry cell, but the electrolyte is a basic KOH paste. This change in design eliminates the buildup of ammonia gas and maintains the zinc electrode, which corrodes more slowly under basic, or alkaline, conditions.

Lead Storage Batteries People depend on lead storage batteries to start their cars. A **battery** is a group of voltaic cells connected together. A 12-V car battery consists of six voltaic cells connected together. Each cell produces about 2 V and consists of lead grids, as shown in Figure 21.5. One set of grids, the anode, is packed with spongy lead. The other set, the cathode, is packed with lead(IV) oxide (PbO_2). The electrolyte for both half-cells in a lead storage battery is sulfuric acid. Using the same electrolyte for both half-cells allows the cell to operate without a salt bridge or porous separator. The half-reactions are as follows:

Oxidation: $Pb(s) + SO_4^{2-}(aq) \longrightarrow PbSO_4(s) + 2e^-$

Reduction: $PbO_2(s) + 4H^+(aq) + SO_4^{2-}(aq) + 2e^- \longrightarrow PbSO_4(s) + 2H_2O(l)$

When a lead storage battery discharges, it produces the electrical energy needed to start a car. The overall spontaneous redox reaction that occurs is the sum of the oxidation and reduction half-reactions.

$$Pb(s) + PbO_2(s) + 2H_2SO_4(aq) \longrightarrow 2PbSO_4(s) + 2H_2O(l)$$

This equation shows that lead(II) sulfate forms during discharge. The sulfate slowly builds up on the plates, and the concentration of the sulfuric acid electrolyte decreases.

READING SUPPORT

Build Reading Skills: ***Compare and Contrast*** An alkaline battery is actually a dry cell, whereas a lead storage battery is considered to be a true battery. ***How are alkaline batteries and lead storage batteries similar? How are they different?***

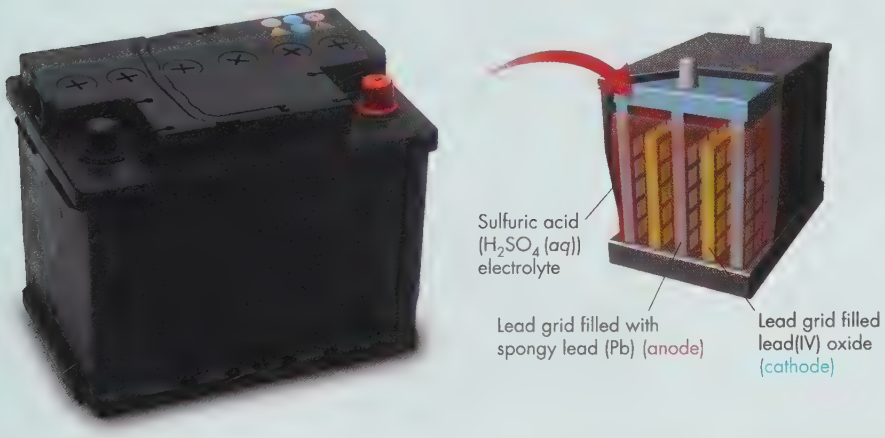

Figure 21.5 Lead Storage Battery One cell of a 12-V lead storage battery is illustrated here. Current is produced when lead at the anode and lead(IV) oxide at the cathode are both converted to lead(II) sulfate. These processes decrease the sulfuric acid concentration in the battery. Reversing the reaction recharges the battery.

Professional Development Note — Car Battery

The forerunner of today's car battery was built by the French physicist Gaston Plant in 1859. Plant's first battery consisted of a single cell containing two sheets of lead separated by rubber strips and immersed in a 10% sulfuric acid solution. A year later, he presented a battery consisting of nine cells enclosed in box with outside terminals to the Académie des sciences (French Academy of Sciences). Plant's invention was significant because it provided the first means of storing electricity.

Explore

Teacher Demo

PURPOSE Students will observe a simple version of the lead storage battery.

MATERIALS 2 strips of lead, wooden rod, 2 connecting wires, 250-mL beaker, dilute sulfuric acid (H_2SO_4), 6-V DC power supply, doorbell

SAFETY Sulfuric acid is corrosive. Wear safety goggles, gloves, and a lab apron.

PROCEDURE Attach two lead strips to a wooden rod so that the strips hang vertically in a 250-mL beaker. Place the strips 4 cm apart. Pour sufficient dilute sulfuric acid into the beaker to cover two-thirds of each strip. Connect a 6-V DC power supply to the strips with wires, and charge the battery for a few minutes. Then, connect the cell to a doorbell.

EXPECTED OUTCOME Students observe that after charging the battery, the bell rings. Discuss the half-cell reactions that occur. Ask students to write the shorthand notation for the electrochemical cell.

$[Pb(s) \mid PbSO_4(s) \parallel PbO_2(s) \mid PbSO_4(s)]$

Explain

START A CONVERSATION Direct students' attention to Figure 21.5. Call attention to the grids, two containing Pb and two containing PbO_2. **Ask** What are the oxidation numbers of the metal lead (Pb) and the lead in lead(IV) oxide (PbO_2)? *(oxidation number of elemental Pb is 0; oxidation number of Pb in PbO_2 is +4.)* **Ask** Which is the anode and which is the cathode? *(Pb is the anode and PbO_2 is the cathode.)* How do you know? *(Pb can only lose electrons and be oxidized, and Pb^{4+} can gain electrons and be reduced.)* Write on the board the overall reaction for the battery when it is discharging. Call attention to the products ($PbSO_4$ and H_2O) and note that Pb is oxidized to form $PbSO_4$ and Pb^{4+} (in PbO_2) is reduced to also form $PbSO_4$. **Ask** What is the oxidation number of the lead in $PbSO_4$? *(+2; Pb is oxidized to Pb^{2+} and Pb^{4+} is reduced to Pb^{2+}.)*

Answers

FIGURE 21.4 In both the alkaline battery and the dry cell, zinc is oxidized and MnO_2 is reduced.

Explain

Using Voltaic Cells as Energy Sources

MAKING CONNECTIONS Point out that fuel cells were developed for space travel where lightweight, reliable power systems were needed. Explain that fuel cells differ from lead storage batteries in that they are not self-contained. Their operation depends on a steady flow of fuel and oxygen into the cell—where combustion takes place—and the flow of the combustion product out of the cell.

Explain that in the case of the hydrogen fuel cell, the product is pure water. Convey that both the electricity generated and the water produced is consumed in space flights. Tell students that fuel cells convert 75% of the available energy into electricity, in contrast with a conventional electric power plant that converts about 35 to 40% of the energy of coal to electricity.

Point out fuels other than hydrogen can also be used, for example, ammonia (NH_3), hydrazine (N_2H_4), and methane (CH_4). Students may be interested in the equations for the reactions that take place in these cells.

$$4NH_3(g) + 3O_2(g) \rightarrow 2N_2(g) + 6H_2O(g)$$
$$2N_2H_4(g) + 2O_2(g) \rightarrow 2N_2(g) + 4H_2O(g)$$
$$CH_4(g) + 2O_2(g) \rightarrow CO_2(g) + 2H_2O(g)$$

Explain that in each case, the products are gases and water vapor which are normally found in Earth's atmosphere.

Extend

Connect to TECHNOLOGY

Divide the class into groups of three or four students. Have them research the use of fuel cells in the space shuttle and by utility companies. Ask them to prepare posters showing different types of fuel cells and their applications. Where possible, have students include the half-cell and overall reactions for each fuel cell. Have them describe the advantages gained by using a fuel cells rather than more conventional sources of electrical energy.

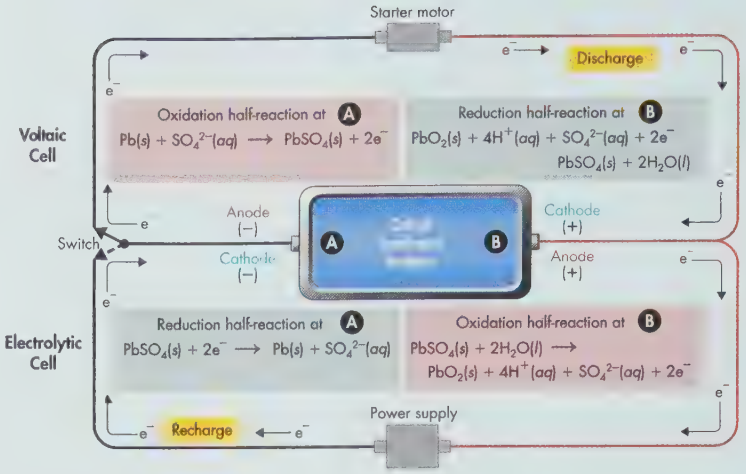

Figure 21.6 Discharge and Recharge of a Lead-Acid Battery The lead-acid battery in an automobile acts as a voltaic cell (top) when it supplies current to start the engine. Some of the power from the running engine is used to recharge the battery, which then acts as an electrolytic cell (bottom). You will learn more about electrolytic cells in Lesson 21.3.

The reverse reaction occurs when a lead storage battery is recharged. This reaction occurs whenever the car's generator is working properly.

$$2PbSO_4(s) + 2H_2O(l) \longrightarrow Pb(s) + PbO_2(s) + 2H_2SO_4(aq)$$

This is not a spontaneous reaction. To make the reaction proceed as written, a direct current must pass through the cell in a direction opposite that of the current flow during discharge. The processes that occur during the discharge and recharge of a lead-acid battery are summarized in Figure 21.6. In theory, a lead storage battery can be discharged and recharged indefinitely, but in practice its lifespan is limited. Small amounts of lead(II) sulfate fall from the electrodes and collect on the bottom of the cell. Eventually, the electrodes lose so much lead(II) sulfate that the recharging process is ineffective or the cell is shorted out. The battery must then be replaced.

Fuel Cells To overcome the disadvantages associated with lead storage batteries, cells with renewable electrodes have been developed. Such cells, called **fuel cells,** are voltaic cells in which a fuel substance undergoes oxidation and from which electrical energy is continuously obtained. Fuel cells do not have to be recharged. They can be designed to emit no air pollutants and to operate more quietly and more cost-effectively than a conventional electrical generator.

Perhaps the simplest fuel cell involves the reaction of hydrogen gas and oxygen gas. The only product of the reaction is liquid water. In the hydrogen–oxygen fuel cell shown in Figure 21.7a, there are three compartments separated from one another by two electrodes. The electrodes are usually made of carbon. Oxygen (the oxidizing agent) from the air flows into the cathode compartment. Hydrogen (the fuel) flows into the anode compartment. The anode and cathode are separated by a thin membrane that allows hydrogen ions to pass through but not electrons. The membrane therefore acts as a salt bridge. Electrons from the oxidation half-reaction at the anode pass through an external circuit to enter the reduction half-reaction at the cathode.

UbD Check for Understanding

The Essential Question How is energy produced in an electrochemical process?

To assess students understanding of voltaic cells, give students one to two minutes to explain, (orally, written, or visually) how a voltaic cell produces energy.

ADJUST INSTRUCTION If students are struggling in their response, direct them to Figure 21.3. Project the figure on the board or a screen, and use various colors of highlighters to visually show each step of how a voltaic-cell works.

The half-reactions in this type of hydrogen–oxygen fuel cell are as follows:

Oxidation: $2H_2(g) \longrightarrow 4H^+(aq) + 4e^-$ (at anode)

Reduction: $O_2(g) + 4H^+(aq) + 4e^- \longrightarrow 2H_2O(g)$ (at cathode)

The overall reaction is the oxidation of hydrogen to form water.

$$2H_2(g) + O_2(g) \longrightarrow 2H_2O(g)$$

Other fuels, such as methane (CH_4) and ammonia (NH_3), can be used in place of hydrogen. Other oxidizing agents, such as chlorine (Cl_2) and ozone (O_3), can be used in place of oxygen.

Since the 1960s, astronauts have used fuel cells as an energy source aboard spacecraft. Hydrogen–oxygen fuel cells with a mass of approximately 100 kg each were used in the Apollo spacecraft missions. Fuel cells are well suited for extended space missions because they offer a continuous energy source that releases no pollutants. On space shuttle missions, for example, astronauts drink the water produced by onboard hydrogen–oxygen fuel cells.

The use of fuel cells is no longer limited to space travel. Scientists and engineers have developed fuel-cell cars. These vehicles, such as the one shown in Figure 21.7b, are propelled by electric motors, which are powered by fuel cells. Fuel-cell vehicles can be fueled with pure hydrogen gas, which is stored in high-pressure tanks. However, more research and development is needed before fuel-cell vehicles will predominate the roadways. Currently, fuel cells are expensive to make, and it is difficult to store hydrogen. Nevertheless, you may soon be seeing fuel-cell cars, buses, and bicycles. You may even one day own a cellphone or laptop that is powered by a miniature fuel cell.

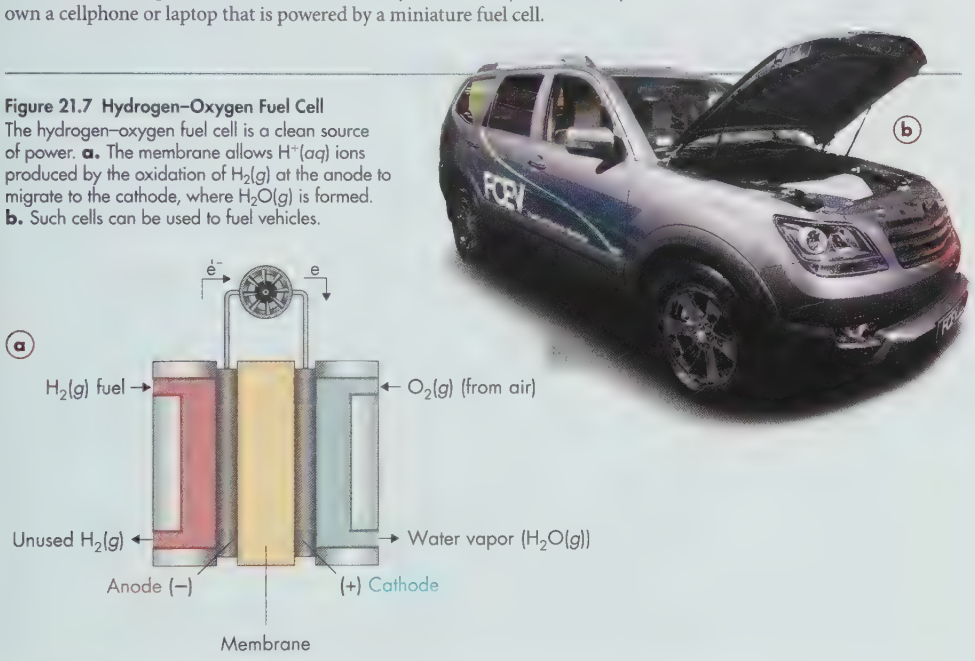

Figure 21.7 Hydrogen–Oxygen Fuel Cell
The hydrogen–oxygen fuel cell is a clean source of power. **a.** The membrane allows $H^+(aq)$ ions produced by the oxidation of $H_2(g)$ at the anode to migrate to the cathode, where $H_2O(g)$ is formed. **b.** Such cells can be used to fuel vehicles.

Professional Development Note

Electroplating

Electroplating is the use of electrolysis to deposit a thin coating of metal on an object, often to enhance its appearance or value. Materials often used for electroplating include gold, silver, copper, nickel, and chromium. In an electrolytic cell, used for plating, the object to be plated is the cathode and the anode is the plating metal. The cathode in an electroplating apparatus must be able to conduct electricity. Thus, one might think that nonmetallic substances such as wood, plastic, and leather could not be electroplated. However, chromium-plated plastic automobile parts enhance the appearance of most cars. Interested students may want to research the pretreatment of plastics that makes electroplating possible, or how a base metal can be electroplated with an alloy, such as brass or bronze.

Explain

Connect to ENGINEERING

Tell students that electric cars are quiet and nonpolluting—no noisy engines spew noxious gases into the atmosphere. So why have car makers not built, promoted, and sold many electric vehicles? Have interested students research the current status of electric cars in the marketplace. Have them find out what obstacles stand in the way of mass usage of these cars. Students could choose to write a report or prepare an oral presentation. *(One obstacle that students may discover is the need for inexpensive, lightweight batteries for efficient storing of electrical energy to lengthen the distance of travel without recharging.)*

Evaluate

Informal Assessment

Have students make a sketch of a tin/lead voltaic cell ($Sn \mid SnSO_4 \parallel PbSO_4 \mid Pb$). Students should label the cathode and anode, and indicate the direction of electron flow.

(Tin is the anode; lead is the cathode. The electrons flow from tin to lead.) Ask students to then write the equations for the half-reactions.

$$[Sn(s) \rightarrow Sn^{2+}(aq) + 2e^-$$

$$Pb^{2+}(aq) + 2e^- \rightarrow Pb(s)]$$

Then, have students complete the 21.1 Lesson Check.

Reteach

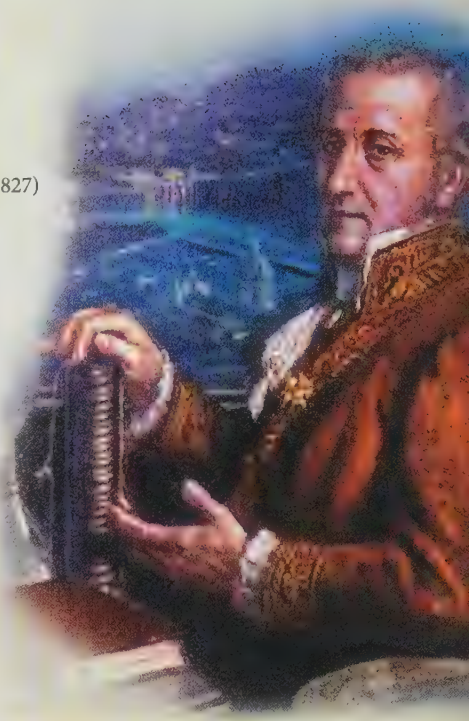
Emphasize that a chemical reaction can produce a flow of electrons or a flow of electrons can cause a chemical reaction to occur. Note that reduction always occurs at the cathode, and oxidation always occurs at the anode. Discuss the half-reactions for the charging process in a lead cell and compare them to the half-reactions when the cell is producing electric current.

CHEMISTRY & YOU

Tell students that Italian physicist Alesandro Volta had already been experimenting with static electricity when, in 1780, his friend Luigi Galvani demonstrated that a current of electricity could be generated if two different metals, copper and zinc, were placed in contact with the muscle of a frog. At that time, scientists believed that nerves acted as water pipes. Galvani was convinced that he'd discovered a new form of electricity—one that was generated by animal tissues and transmitted through the nerves as an electrical fluid. Volta later showed that animal tissue was not necessary—current flowed with only the two dissimilar metals. Galvani's research led to the eventual discovery that nerves transmit electrical impulses. Pose the following challenge to students. *Compare and contrast the electrical current generated by a nerve cell and the current generated by a voltaic cell.* You may need to assist students in the following ways:

- Nerve cells contain sodium and potassium ions.
- Nerve impulses are generated when sodium ions flow into the cell and potassium ions flow out of the cell in response to a stimulus, creating an imbalance in charge across the membrane.

CHEMISTRY & YOU: HISTORY



Alessandro Volta

In the late 1770s, Italian physicist Alessandro Volta (1745–1827) discovered that contact between two different metals could produce electricity. Using this knowledge, Volta began experimenting with ways to produce a steady electric current. In 1799, he built a stack of alternating zinc and copper discs, separated by pasteboard soaked in saltwater. When he connected a wire to both ends of the pile, a steady current flowed. This device, called the "voltaic pile," was the first battery.

Volta found that different types of metals could change the amount of current produced and that he could increase the current by adding disks to the stack. Later, he improved on the pile by creating a "crown of cups"—separate cups of salt solution linked by metal straps. In 1810, Napoleon Bonaparte gave Volta the title of Count in honor of his work, and in 1881 the unit of electrical potential was named the "volt" in Volta's honor.

THE BATTERY REINVENTED Modern batteries look much different from Volta's alternating zinc and copper discs.

Take It Further

1. Explain What was the function of the pasteboard soaked in saltwater in Volta's battery?

2. Infer What is one possible reason why Volta's "crown of cups" would generate more current than a "voltaic pile"?

21.1 LessonCheck

1. Identify What type of reaction occurs during an electrochemical process?

2. Describe What is the source of electrical energy produced in a voltaic cell?

3. List What are three examples of technologies that use electrochemical processes to supply electrical energy?

4. Compare Which metal is more easily oxidized, lead or calcium?

5. Apply Concepts What is the electrolyte in a lead storage battery? Write the half-reactions for such a battery.

6. Describe Write the overall reaction that takes place in a hydrogen–oxygen fuel cell. What product(s) are formed? Describe the half-reactions in this cell.

7. Predict What happens when a strip of copper is dipped into a solution of iron(II) sulfate?

Lesson Check Answers

1. a redox reaction
2. spontaneous redox reactions within the cell
3. fuel cells, lead storage batteries, and dry cells
4. calcium
5. concentrated sulfuric acid;
   Anode:
   $Pb(s) + SO_4^{2-}(aq) \rightarrow PbSO_4(s) + 2e^-$
   Cathode:
   $PbO_2(s) + 4H^+(aq) + SO_4^{2-}(aq) + 2e^- \rightarrow PbSO_4(s) + 2H_2O(l)$
6. $2H_2(g) + O_2(g) \rightarrow 2H_2O(l)$; water is the product. H_2 is oxidized at the anode; O_2 is reduced at the cathode.
7. no reaction

21.2 Half-Cells and Cell Potentials

CHEMISTRY & YOU

Q: *How can you calculate the electrical potential of a cell in a laptop battery?* Batteries provide current to power lights and many kinds of electronic devices—such as the laptop shown here. The electrical potential between the negative and positive terminals of a lithium laptop battery is 3.7 V. In this lesson, you will learn how to calculate electrical potential.

Key Questions

- *What causes the electrical potential of an electrochemical cell?*
- *How can you determine the standard reduction potential of a half-cell?*
- *How can you determine if a redox reaction is spontaneous?*

Vocabulary

- electrical potential
- reduction potential
- cell potential
- standard cell potential
- standard hydrogen electrode

Electrical Potential

What causes the electrical potential of an electrochemical cell?

The **electrical potential** of a voltaic cell is a measure of the cell's ability to produce an electric current. Electrical potential is usually measured in volts (V). The potential of an isolated half-cell cannot be measured. For example, you cannot measure the electrical potential of a zinc half-cell or of a copper half-cell separately. When these two half-cells are connected to form a voltaic cell, however, the difference in potential can be measured.

The electrical potential of a cell results from a competition for electrons between two half-cells. The half-cell that has a greater tendency to acquire electrons is the one in which reduction occurs. Oxidation occurs in the other half-cell. The tendency of a given half-reaction to occur as a reduction is called the **reduction potential.** The half-cell in which reduction occurs has a greater reduction potential than the half-cell in which oxidation occurs. The difference between the reduction potentials of the two half-cells is called the **cell potential.**

$$\text{cell potential} = \left(\begin{array}{c}\text{reduction potential}\\ \text{of half-cell in which}\\ \text{reduction occurs}\end{array}\right) - \left(\begin{array}{c}\text{reduction potential}\\ \text{of half-cell in which}\\ \text{oxidation occurs}\end{array}\right)$$

$$\text{or } E_{cell} = E_{red} - E_{oxid}$$

The **standard cell potential** (E°_{cell}) is the measured cell potential when the ion concentrations in the half-cells are 1*M*, any gases are at a pressure of 101 kPa, and the temperature is 25°C. The symbols E°_{red} and E°_{oxid} represent the standard reduction potentials for the reduction and oxidation half-cells, respectively. The relationship between these values follows the general relationship for cell potential above.

$$E^\circ_{cell} = E^\circ_{red} - E^\circ_{oxid}$$

Focus on ELL

1 CONTENT AND LANGUAGE Begin the lesson by writing the word *potential* on the board and pronouncing it slowly. Explain that the word potential comes from the Latin *potens* meaning "power." Explain that electrical potential is the ability of a cell to produce an electric current.

2 FRONTLOAD THE LESSON Read the first page of the text aloud slowly, and with the participation of the class, summarize the contents in a sentence or two. Ask students to write the summary in their notebooks. Continue this process of summarizing the principal ideas for each heading.

3 COMPREHENSIBLE INPUT Create a voltaic cell and have students assist you in calculating its cell potential. Then, connect a voltmeter to the electrodes and allow students to observe the display to compare the calculated results to the actual potential.

Key Objectives

- **21.2.1 IDENTIFY** what causes the electrical potential of an electrochemical cell.
- **21.2.2 DETERMINE** the standard reduction potential of a half-cell.
- **21.2.3 DETERMINE** if a redox reaction is spontaneous or nonspontaneous.

Additional Resources

Reading and Study Workbook, Lesson 21.2

Available Online or on Digital Media:

- Teaching Resources, Lesson 21.2 Review
- Laboratory Manual, Lab 47

PearsonChem.com

Engage

CHEMISTRY & YOU Have students read the opening paragraph. Point out that many rechargeable batteries contain lithium. **Ask** What characteristic makes lithium a good choice for battery terminal? *(It is the most easily oxidized metal element.)* Have students keep this characteristic in mind as they proceed with the lesson.

Activate Prior Knowledge

Prepare students for the content in this lesson by asking a few questions about electrochemical and voltaic cells: **Ask** What process goes on at the anode? *(oxidation)* **Ask** What process goes on the cathode? *(reduction)* **Ask** In which process are electrons lost? *(oxidation)*

TAKE IT FURTHER

1. to conduct current between the two metals
2. The "crown of cups" has a sufficient amount of electrolyte solution, whereas the "voltaic pile" can easily dry out.

Foundations for Reading

BUILD VOCABULARY Clarify that the word *cell* as used in this lesson refers to electrochemical cells that convert chemical energy into electrical energy. Have students use their understanding of electrochemical cells and of potential energy to predict the meaning of the vocabulary words. Then, have students check and correct their predictions.

READING STRATEGY Have students monitor their understanding by identifying what they don't yet understand after reading a section. Have students attempt to rewrite the section using a bulleted list, or encourage them to ask for help. Then, have students write a statement showing a clarified understanding of the section.

Explain

Electrical Potential

USE VISUALS Have students study the diagram in Figure 21.8. **Ask** What is the significance of the standard hydrogen electrode and how is it different from other electrodes? *(It has been assigned a standard reduction potential of 0.00 V at 25°C.)* **Ask** What does the standard hydrogen half-cell consist of? *(A platinum electrode with hydrogen gas at atmospheric pressure bubbling over its surface; the electrode is immersed in 1.00M acid solution at 25°C.)*

USE AN ANALOGY Students may be confused by the arbitrary assignment of 0.00 V to the hydrogen half-cell. Use a diagram of the Celsius temperature scale as an analogy. Explain that when the Celsius temperature scale was invented, 0°C was arbitrarily assigned to the temperature at which water freezes; all measured temperatures are relative to that assigned value. Explain that temperatures higher than the freezing point of water are positive values of temperature and temperatures lower than 0°C are negative values of temperature.

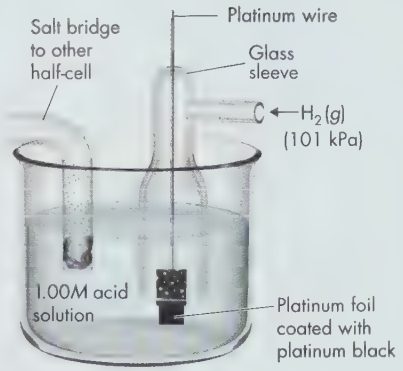


Figure 21.8 Standard Hydrogen Electrode The standard hydrogen electrode is arbitrarily assigned a standard reduction potential of 0.00 V at 25°C.

Half-cell potentials cannot be measured directly, so scientists have chosen an arbitrary electrode to serve as a reference. The **standard hydrogen electrode** is used with other electrodes, so the reduction potentials of the other cells can be measured. The standard reduction potential of the hydrogen electrode has been assigned a value of 0.00 V. The standard hydrogen electrode, which is illustrated in Figure 21.8, consists of a platinum electrode immersed in a solution with a hydrogen-ion concentration of 1*M*. The solution is at 25°C. The electrode itself is a small square of platinum foil coated with finely divided platinum, known as platinum black. Hydrogen gas at a pressure of 101 kPa is bubbled around the platinum electrode. The half-cell reaction that occurs at the platinum black surface is as follows:

$$2H^+(aq, 1M) + 2e^- \rightleftharpoons H_2(g, 101\ kPa) \quad E^\circ_{H^+} = 0.00\ V$$

The double arrows in the equation indicate that the reaction is reversible. The symbol $E^\circ_{H^+}$ represents the standard reduction potential of H^+. The standard reduction potential of H^+ is the tendency of H^+ ions to acquire electrons and be reduced to $H_2(g)$. Whether this half-cell reaction occurs as a reduction or as an oxidation is determined by the reduction potential of the half-cell to which the standard hydrogen electrode is connected.

Standard Reduction Potentials

How can you determine the standard reduction potential of a half-cell?

A voltaic cell can be made by connecting a standard hydrogen half-cell to a standard zinc half-cell, as shown in Figure 21.9. To determine the overall reaction for this cell, first identify the half-cell in which reduction takes place. In all electrochemical cells, reduction takes place at the cathode, and oxidation takes place at the anode. A voltmeter gives a reading of +0.76 V when the zinc electrode is connected to the negative terminal and the hydrogen electrode is connected to the positive terminal. The zinc is oxidized, which means that it is the anode. Hydrogen ions are reduced, which means that the hydrogen electrode is the cathode. You can now write the half-reactions and the overall cell reaction.

Oxidation: $Zn(s) \longrightarrow Zn^{2+}(aq) + 2e^-$ (at anode)

Reduction: $2H^+(aq) + 2e^- \longrightarrow H_2(g)$ (at cathode)

Cell reaction: $Zn(s) + 2H^+(aq) \longrightarrow Zn^{2+}(aq) + H_2(g)$

You can determine the standard reduction potential of a half-cell by using a standard hydrogen electrode and the equation for standard cell potential. In the zinc–hydrogen cell, zinc is oxidized and hydrogen ions are reduced. Let $E^\circ_{red} = E^\circ_{H^+}$ and $E^\circ_{oxid} = E^\circ_{Zn^{2+}}$ in the standard cell potential equation.

$$E^\circ_{cell} = E^\circ_{red} - E^\circ_{oxid}$$

$$E^\circ_{cell} = E^\circ_{H^+} - E^\circ_{Zn^{2+}}$$

Differentiated Instruction

L1 SPECIAL NEEDS STUDENTS Engage students in a role playing activity to reinforce the direction of electron flow in a voltaic cell. Give students small cards with a large e^- printed on each one. Divide students into pairs. Let one student role play being an anode and the other a cathode. The anode should hand one or more cards to the cathode.

LPR LESS PROFICIENT READERS Have pairs of students look at the diagram of the voltaic cell in Figure 21.9. Have them trace the movement of the electrons from one electrode to the other. They should be able to explain that the electrons travel up from the zinc anode into the external wire, through the voltmeter, and down through the wire into the hydrogen/platinum cathode. Have them identify where oxidation is taking place and where reduction is taking place. Refer them to Table 21.2 on page 740 to find the appropriate half-cell reactions and have them write the overall reaction for the cell.

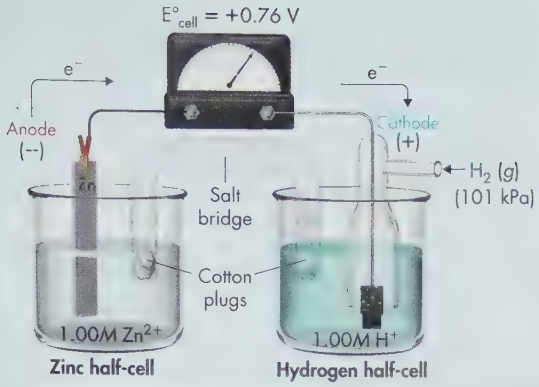

Figure 21.9 Zinc–Hydrogen Cell This voltaic cell consists of zinc and hydrogen half-cells.
Interpret Diagrams *Where does reduction occur? What species is reduced in this cell?*

The cell potential ($E°_{cell}$) is measured at +0.76 V. The reduction potential of the hydrogen half-cell is a defined standard: $E°_{H^+}$ always equals 0.00 V. Substituting these values into the preceding equation will give the standard reduction potential for the zinc half-cell.

$$+0.76\text{ V} = 0.00\text{ V} - E°_{Zn^{2+}}$$
$$E°_{Zn^{2+}} = -0.76\text{ V}$$

The standard reduction potential for the zinc half-cell is −0.76 V. The value is negative because the tendency of zinc ions to be reduced to zinc metal in this cell is less than the tendency of hydrogen ions to be reduced to hydrogen gas.

Many different half-cells can be paired with the hydrogen half-cell in a similar manner. Using this method, the standard reduction potential for each half-cell can be obtained. For a standard copper half-cell, for example, the measured standard cell potential is +0.34 V when the copper electrode is connected to the positive electrode and the hydrogen electrode is connected to the negative terminal. Copper is the cathode, and copper ions are reduced to copper metal when the cell operates. The hydrogen half-cell is the anode, and hydrogen gas is oxidized to hydrogen ions. You can calculate the standard reduction potential for copper as follows:

$$E°_{cell} = E°_{red} - E°_{oxid}$$
$$E°_{cell} = E°_{Cu^{2+}} - E°_{H^+}$$
$$+0.34\text{ V} = E°_{Cu^{2+}} - 0.00\text{ V}$$
$$E°_{Cu^{2+}} = +0.34\text{ V}$$

This value is positive because the tendency for copper ions to be reduced in the cell is greater than the tendency of hydrogen ions to be reduced.

Table 21.2 on the following page lists some standard reduction potentials at 25°C. The half-reactions are arranged in increasing order of their tendency to occur in the forward direction—that is, as a reduction. Thus, the half-reactions at the top of the table have the least tendency to occur as reductions. The half-reactions at the bottom of the table have the greatest tendency to occur as reductions.

CHEMISTRY & YOU

Q: *What do you need to know to calculate the electrical potential of a cell in a laptop battery?*

UbD Check for Understanding

How can you determine the standard reduction potential of a half-cell?

Assess students' understanding of the role of the standard hydrogen electrode in determining standard reduction potentials by having them write a one-minute summary explaining how a standard hydrogen electrode and the standard cell potential equation are used to determine the standard reduction potential of a metal. *(A voltaic cell is created using the metal as one half-cell and a standard hydrogen electrode as the other half-cell. The cell potential ($E°_{cell}$) is measured and plugged into the standard cell potential equation along with the standard reduction potential of the hydrogen electrode. Once the cathode and anode in the reaction are identified, the equation can be solved for the standard reduction potential of the metal.)*

Explore

Standard Reduction Potentials

Teacher Demo

PURPOSE Students will observe the galvanic corrosion of iron compared to copper.

MATERIALS 2 pennies, metal wires from twist ties, table salt, paper towel

PROCEDURE Thoroughly clean the pennies and the wires. Moisten a paper towel with tap water and sprinkle it with salt. Wrap one wire around a penny and place it on the paper towel. Place an unwrapped penny and a coil of wire on the paper towel as a control. Observe what happens after at least 24 hours.

EXPECTED OUTCOMES Iron corroded; copper did not. Ask students to explain the outcomes. *(In galvanic corrosion, the corrosion rate (oxidation) of one metal accelerates while that of the other is decreased. Because iron is more active than copper, its corrosion was accelerated.)*

Answers

FIGURE 21.9 Reduction occurs at the cathode. In this cell, hydrogen ions are reduced to hydrogen gas.

Explain

APPLY CONCEPTS Explain that the two half-cells of a voltaic cell are competing for electrons and that oxidation or reduction could occur in either cell. Point out that the half-cell with the more positive reduction potential will win the competition and undergo reduction; oxidation will occur in the other half-cell. Explain that the potential produced by the electrochemical cell is the difference in the reduction potentials of the two half-cell reactions. Explain that the quantitative value of any half-cell potential is obtained by measuring it against the standard hydrogen electrode. Point out that Table 21.2 contains tabulated values for some half-cells. These can be used to calculate cell potentials.

Table 21.2

Reduction Potentials at 25°C With 1M Concentrations of Aqueous Species

	Electrode	Half-reaction	E° (V)

	F_2/F^-	$F_2 + 2e^- \longrightarrow 2F^-$	+2.87

Increasing tendency to occur as a reduction (stronger oxidizing agent)

Differentiated Instruction

L1 STRUGGLING STUDENTS Some students may have trouble remembering which reactions in Table 21.2 have the greatest tendency to occur as reductions. Have them compare the table with the activity series of metals in Table 21.1 in Lesson 21.1. Point out that the most active metals are at the top of Table 21.1; ions of these same metals are at the top of Table 21.2. Explain that because active metals lose electrons easily, they are most easily oxidized. By the same reasoning, point out that their ions are least likely to be reduced.

L3 ADVANCED STUDENTS Have students investigate the practice of attaching large pieces of magnesium, called hull anodes, to the hulls of ships having steel (iron) hulls. Ask them to explain the reason for this practice and provide any supporting figures they can. *(The more active metal, magnesium, is oxidized rather than the iron. The reduction potential for magnesium (Mg^{2+}/Mg) is –2.37 V and the reduction potential for iron (Fe^{3+}/Fe) is –0.036 V).*

Calculating Standard Cell Potentials

How can you determine if a redox reaction is spontaneous?

In an electrochemical cell, the half-cell reaction having the more positive (or less negative) reduction potential occurs as a reduction in the cell. You can use the known standard reduction potentials for the half-cells (from Table 21.2) to predict the half-cells in which reduction and oxidation will occur and to find the E°_{cell} value without having to actually assemble the cell. **If the cell potential for a given redox reaction is positive, then the reaction is spontaneous as written. If the cell potential is negative, then the reaction is non-spontaneous.** This latter reaction will be spontaneous in the reverse direction, and the cell potential will then have a numerically equal but positive value.

SampleProblem 21.1

Determining Reaction Spontaneity

Show that the following redox reaction between zinc metal and silver ions is spontaneous.

$$Zn(s) + 2Ag^+(aq) \longrightarrow Zn^{2+}(aq) + 2Ag(s)$$

1 Analyze **List the knowns and the unknown.**
Identify the half-reactions, and calculate the standard cell potential ($E^\circ_{cell} = E^\circ_{red} - E^\circ_{oxid}$). If E°_{cell} is positive, the reaction is spontaneous.

KNOWNS
cell reaction: $Zn(s) + 2Ag^+(aq) \longrightarrow Zn^{2+}(aq) + 2Ag(s)$

UNKNOWN
Is the reaction spontaneous?

2 Calculate **Solve for the unknown.**

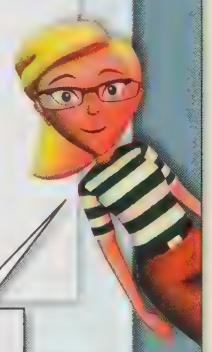
First, identify the half-reactions.

Oxidation: $Zn(s) \longrightarrow Zn^{2+}(aq) + 2e^-$

Reduction: $Ag^+(aq) + e^- \longrightarrow Ag(s)$

Write both half-cells as reductions with their standard reduction potentials.

$Zn^{2+}(aq) + 2e^- \longrightarrow Zn(s)$ $\quad E^\circ_{Zn^{2+}} = -0.76\,V$



$Ag^+(aq) + e^- \longrightarrow Ag(s)$ $\quad E^\circ_{Ag^+} = +0.80\,V$

Calculate the standard cell potential.

$$E^\circ_{cell} = E^\circ_{red} - E^\circ_{oxid} = E^\circ_{Ag^+} - E^\circ_{Zn^{2+}}$$
$$= +0.80\,V - (-0.76\,V) = +1.56\,V$$

$E^\circ_{cell} > 0$, so the reaction is spontaneous.

3 Evaluate **Does the result make sense?** Zinc is above silver in the activity series for metals. It makes sense that zinc is oxidized in the presence of silver ions.

Use Table 21.2 to look up the standard reduction potentials for the half-cells.

8. Determine whether the following redox reaction will occur spontaneously:
$3Zn^{2+}(aq) + 2Cr(s) \longrightarrow 3Zn(s) + 2Cr^{3+}(aq)$

9. Is this redox reaction spontaneous as written?
$Co^{2+}(aq) + Fe(s) \longrightarrow Fe^{2+}(aq) + Co(s)$

Foundations for Math

ADDING AND SUBTRACTING INTEGERS To add integers with different signs, find the absolute value of each number. Then, subtract the lesser absolute value from the greater absolute value. The sum has the sign of the integer with the greater absolute value. Subtracting an integer is the same as adding its opposite. For example: 2 – 3 is the same as 2 + (–3). Now follow the rules for adding integers with different signs to get
a sum of –1.

In **Sample Problem 21.1,** explain that the rules for adding and subtracting integers also apply to real numbers. The standard cell potential is calculated as follows:

$E^\circ = 0.8\,V - (-0.76\,V)$

$E^\circ = 0.8\,V + (0.76\,V)$ Add the opposite.

$E^\circ = 1.56\,V$ Find the sum.

Explore

Calculating Standard Cell Potentials

Class Activity

PURPOSE Students become familiar with combining reduction half-reactions.

PROCEDURE Divide the class into groups of three or four. Have them use Table 21.2 to combine half-reactions and create cells having potentials that fall in the following ranges: +2.5 V, +2.4 V to +1.4 V, +1.0 V to +0.5 V, and +0.4 V to +0.1 V.

EXPECTED OUTCOMES Several cells could be created in each category. Typical cells might be Na/Na^+ with Sn^{2+}/Sn, +2.57 V; Mg^{2+}/Mg with Pb^{2+}/Pb, +2.24 V; Ca^{2+}/Ca with Al^{3+}/Al, 1.21 V; $PbSO_4$/Pb with Ni^{2+}/Ni, 0.11 V.

Sample Practice Problem

Determine the half-reactions of the following reaction. Then, determine if the reaction will occur spontaneously. Explain how you determined your response.

$Fe(s) + Cl_2(g) \rightarrow Fe^{2+}(aq) + 2Cl^-(aq)$

$Cl_2 + 2e^- \rightarrow 2Cl^-$ $\quad E^\circ_{Cl^-} = +1.36V$

$Fe^{2+} + 2e^- \rightarrow Fe$ $\quad E^\circ_{Fe^{2+}} = -0.44V$

[The reaction is not spontaneous since the standard cell potential is a negative value: $E^\circ = -1.8$ V]

Answers

8. $E^\circ_{cell} = -0.02$ V; $E^\circ_{cell} < 0$, so the reaction is not spontaneous.

9. $E^\circ_{cell} = +0.16$ V ; $E^\circ_{cell} > 0$, so the reaction is spontaneous.

Explain

Misconception Alert

As students work Sample Problems 21.1 and 21.2, they may think that when a half-cell reaction must be multiplied by a factor such as 2 or 3, the $E°$ value must also be multiplied by that factor. Point out that even though two or three times as many electrons are present, the tendency for the electrons to flow is not two or three times greater. The tendency, which is measured by the $E°$ value, remains the same.

MAKING CONNECTIONS Point out that, until now, it has been assumed that reactions in standard half-cells always go in the spontaneous direction. For example, a Ag/Cu cell can be constructed in such a way that the only substance available for oxidation is silver metal and the only substance available for reduction is copper ion. In this case, the reaction is nonspontaneous and the cell potential is negative. Thus, the sign of the cell potential is an indicator of reaction spontaneity. Students will learn in the following lesson that nonspontaneous reactions can be driven by an outside source of energy.

Sample Practice Problem

A. Explain which half-reaction is more likely to be a reduction reaction, a half-reaction with a standard cell potential of –0.12 V or a half reaction with a standard cell potential of +0.12 V. *(The positive standard cell value is more likely to be the reduction reaction since the positive value aligns more to the cathode in a cell.)*

B. A voltaic cell is constructed using the following half-reactions:

$Li^+(aq) + e^- \rightarrow Li(s)$ $\quad E° = -3.05$ V

$Mg^{2+}(aq) + 2e^- \rightarrow Mg(s)$ $\quad E° = -2.37$ V

Determine the standard cell reaction.

$[2Li(s) + Mg^{2+}(aq) \rightarrow Mg(s) + 2Li^+(aq)]$

Sample Problem 21.2

Writing the Cell Reaction

Determine the cell reaction for a voltaic cell composed of the following half-cells:

$Fe^{3+}(aq) + e^- \longrightarrow Fe^{2+}(aq)$ $\quad E°_{Fe^{3+}} = +0.77$ V

$Ni^{2+}(aq) + 2e^- \longrightarrow Ni(s)$ $\quad E°_{Ni^{2+}} = -0.25$ V

1 Analyze **Identify the relevant concepts.** The half-cell with the more positive reduction potential is the one in which reduction occurs (the cathode). The oxidation reaction occurs at the anode. Add the half-reactions, making certain that the number of electrons lost equals the number of electrons gained.

2 Solve **Apply the concepts to this problem.**

First, identify the cathode and the anode.

The Fe^{3+} half-cell has the more positive reduction potential, so it is the cathode. The Ni^{2+} half-cell has the more negative reduction potential, so it is the anode. In this voltaic cell, Fe^{3+} is reduced and Ni is oxidized.

Write the half-cell reactions in the direction in which they actually occur.

Oxidation: $Ni(s) \longrightarrow Ni^{2+}(aq) + 2e^-$ (at anode)

Reduction: $Fe^{3+}(aq) + e^- \longrightarrow Fe^{2+}(aq)$ (at cathode)

If necessary, multiply the half-reactions by the appropriate factor(s) so that the electrons cancel when the half-reactions are added.

$Ni(s) \longrightarrow Ni^{2+}(aq) + 2e^-$

$2[Fe^{3+}(aq) + e^- \longrightarrow Fe^{2+}(aq)]$

Multiply the Fe^{3+} half-cell equation by 2 so that the number of electrons are present in equal numbers on both sides of the equation.

Add the half-reactions.

$Ni(s) \longrightarrow Ni^{2+}(aq) + 2e^-$

$2Fe^{3+}(aq) + 2e^- \longrightarrow 2Fe^{2+}(aq)$

$Ni(s) + 2Fe^{3+}(aq) \longrightarrow Ni^{2+}(aq) + 2Fe^{2+}(aq)$

The electrons lost by the species that is oxidized must be equal to the electrons gained by the species that is reduced.

The half-cell with the more positive reduction potential is the cathode.

10. A voltaic cell is constructed using the following half-reactions:

$Cu^{2+}(aq) + 2e^- \longrightarrow Cu(s)$

$E°_{Cu^{2+}} = +0.34$ V

$Al^{3+}(aq) + 3e^- \longrightarrow Al(s)$

$E°_{Al^{3+}} = -1.66$ V

Determine the cell reaction.

11. A voltaic cell is constructed using the following half-reactions:

$Ag^+(aq) + e^- \longrightarrow Ag(s)$

$E°_{Ag^+} = +0.80$ V

$Cu^{2+}(aq) + 2e^- \longrightarrow Cu(s)$

$E°_{Cu^{2+}} = +0.34$ V

Determine the cell reaction.

Foundations for Math

SUBTRACTING REAL NUMBERS Remind students that scientific calculators are programmed to abide by the rules for order of operations. Emphasize that students should know what keys are available on their calculators and how to use them. Point out that on most scientific calculators, the key marked (+/–), near the ENTER key, makes the following number a negative number. The key marked – by the + key *subtracts* the following number from the number before it. If you confuse the two keys, you will either get a syntax error, or you will get the wrong value.

In **Sample Problem 21.2 and 21.3,** show students the appropriate keystrokes and values needed to find the standard cell potential. The sample problem shows:

$E° = +0.77 \text{ V} - (-0.25) \text{ V}$

The following keystrokes should be used to solve this problem (brackets represent function keys):

.77 [–] [+/–] .25 [=]

Sample Problem 21.3

Calculating the Standard Cell Potential

Calculate the standard cell potential for the voltaic cell described in Sample Problem 21.2. The half-reactions are as follows:

$Fe^{3+}(aq) + e^- \longrightarrow Fe^{2+}(aq)$ $E^\circ_{Fe^{3+}} = +0.77\ V$

$Ni^{2+}(aq) + 2e^- \longrightarrow Ni(s)$ $E^\circ_{Ni^{2+}} = -0.25\ V$

KNOWNS

$E^\circ_{Fe^{3+}} = +0.77\ V$

$E^\circ_{Ni^{2+}} = -0.25\ V$

anode: Ni^{2+} half-cell

cathode: Fe^{3+} half-cell

UNKNOWN

$E^\circ_{cell} = ?$

1 Analyze **List the knowns and the unknown.** Use the equation $E^\circ_{cell} = E^\circ_{red} - E^\circ_{oxid}$ to calculate the standard cell potential.

2 Calculate **Solve for the unknown.**

First, write the equation for the standard cell potential.

$E^\circ_{cell} = E^\circ_{red} - E^\circ_{oxid} = E^\circ_{Fe^{3+}} - E^\circ_{Ni^{2+}}$

Substitute the values for the standard reduction potentials and solve the equation.

$E^\circ_{cell} = +0.77\ V - (-0.25\ V) = +1.02\ V$

3 Evaluate **Does the result make sense?** The reduction potential of the reduction is positive, and the reduction potential of the oxidation is negative. Therefore, E°_{cell} must be positive.

12. Calculate the standard cell potential of a voltaic cell constructed using the half-reactions described in Problem 10.

13. Calculate the standard cell potential of a voltaic cell constructed using the half-reactions described in Problem 11.

If you did Problem 10, you know what the anode and cathode are in this cell.

If you did Problem 11, you know what the anode and cathode are in this cell.

21.2 LessonCheck

14. Explain What causes the electrical potential of a cell?

15. Describe How can you find the standard reduction potential of a half-cell?

16. Review What cell potential values indicate a spontaneous reaction? What cell potential values indicate a nonspontaneous reaction?

17. Calculate Determine whether the following redox reaction will occur spontaneously:

$2Al^{3+}(aq) + 3Mg(s) \longrightarrow 2Al(s) + 3Mg^{2+}(aq)$

18. Calculate Determine the cell reaction and standard cell potential for a voltaic cell composed of the following half-cells:

$Li^+(aq) + e^- \longrightarrow Li(s)$ $E^\circ_{Li^+} = -3.05\ V$

$Mg^{2+}(aq) + 2e^- \longrightarrow Mg(s)$ $E^\circ_{Mg^{2+}} = -2.37\ V$

BIG IDEA MATTER AND ENERGY

19. Why does a lead-acid battery produce energy? Calculate the standard cell potential of one voltaic cell in a lead-acid battery.

Lesson Check Answers

14. Electrical potential of cell results from competition for electrons between two half-cells.

15. by connecting it to a standard hydrogen electrode and measuring the cell potential

16. If the cell potential for a redox reaction is positive, the reaction is spontaneous; if it is negative, the reaction is nonspontaneous.

17. spontaneous; $E^\circ_{cell} = +0.71\ V$

18. $2Li(s) + Mg^{2+}(aq) \rightarrow Mg(s) + 2Li^+(aq)$; $E^\circ_{cell} = +0.68$

19. There is an positive electrical potential between the negative and positive terminals of the battery. Cell reaction: $Pb + PbO_2 + 2H_2SO_4^{2-} \rightarrow 2PbSO_4 + 2H_2O$; $E^\circ_{cell} = +2.05\ V$

Sample Practice Problem

Calculate the standard cell potential of the following reaction to determine whether the reaction will occur spontaneously.

$Pb^{2+}(aq) + 2e^- \rightarrow Pb(s)$ $E^\circ_{Pb^{2+}} = -0.13$

$I_2(s) + 2e^- \rightarrow 2I^-(aq)$ $E^\circ_{I^-} = +0.54$

(spontaneous; $E^\circ_{cell} = +0.67$)

Evaluate

Informal Assessment

Ask students to refer to Table 21.2. Tell students to use the table to create an electrochemical cell that will operate spontaneously. Instruct students to submit the following:

- calculations showing the cell potential
- the equations for the two half-reactions
- the overall cell reaction

Reteach

Use the think-aloud process to help students understand the thought process that is involved in determine the cell potential of a nonspontaneous reaction. On the overhead, write the following equation:

$Cd^{2+}(aq) + Ag(s) \rightarrow Cd(s) + Ag^+(aq)$

Ask What element is being reduced? *(cadmium)* Have students direct you in writing the half-reaction for the reduction. [$Cd^{2+}(aq) + 2e^- \rightarrow Cd(s)$]

Ask What element is being oxidized? *(silver)* Write the half-reaction with student input.

[$Ag(s) \rightarrow Ag(aq) + e^-$]

Guide students through the process of calculating the cell potential. *(−1.20 V)* **Ask** Does the cell operate spontaneously? How do you know?

(No, it has a negative potential.)

Answers

10. $2Al(s) + 3Cu^{2+}(aq) \rightarrow 2Al^{3+}(aq) + 3Cu(s)$

11. $Cu(s) + 2Ag^+(aq) \rightarrow Cu^{2+}(aq) + 2Ag(s)$

12. $E^\circ_{cell} = +2.00\ V$

13. $E^\circ_{cell} = +0.46\ V$

CHEMISTRY & YOU Have students examine the photo of the lemon battery. Then, ask students to recall the discussion of Luigi Galvani's generation of an electric current through a frog's leg in the Chemistry and You feature at the end of Lesson 21.1. Point out that, unlike a frog's leg, a lemon does not have nerves, and yet it still can conduct electricity. Pose the following question to students: *What characteristics do lemon cells share with frog nerve cells that can aid in transmitting an electrical current through their tissues?* You may need to assist students in the following ways:

- Both types of cells contain water.
- Both types of cells have semipermeable membranes.
- Both types of cells have the ability to actively transport ions across their membranes.

Explain

USE VISUALS Draw a diagram on the board of the voltaic cell and circuit created in the activity. Have student volunteers label the different parts. Also have them draw arrows on the diagram to indicate the direction of ion movement to reinforce the concepts they have learned in the chapter.

START A CONVERSATION Encourage students to think of various alterations they could try if they have difficulty getting their lemon battery to work. Possible alterations include using more than one lemon with the nails connected by a wire, using an LED bulb, and using a thinner wire.

CHEMISTRY & YOU: EVERYDAY MATTER

A Lemon Battery

Batteries provide power to many of the electronic devices you may use in your daily life, including laptops, cellphones, and mp3 players. Batteries come in all different shapes and sizes, from the large 12-V battery in cars, to the AAA batteries in calculators, to the tiny batteries in watches.

A battery is essentially a container that contains an anode, where oxidation occurs, a cathode, where reduction occurs, and an electrolyte. Electrons flow from the anode to the cathode through an external circuit, which is usually the device to which the battery is supplying energy. Positive and negative ions move through the electrolyte to complete the circuit.

Did you know that you can make a battery at home with only nails or wires and fruit? Try this activity at home and see how much of a voltage you can generate.

On Your Own

1. For this activity, you will need a **copper nail, screw, or wire** (about 5 cm long) and a **zinc or galvanized nail or screw** (about 5 cm long). These will serve as your electrodes. You will also need a **whole lemon** and a **multimeter** set to measure voltage (if you have one). Clean the electrodes with hot, soapy water, rinse, and dry them. Soften the lemon by rolling it on a table. Be careful not to break the skin.

2. Insert the zinc and copper electrodes into the lemon. The electrodes should not touch and should be about 2–3 cm apart.

3. Briefly touch both electrodes at the same time with your tongue and observe what happens.

4. Measure the voltage of your lemon battery with the multimeter. Attach the positive (red) lead to the copper electrode and the negative (black) lead to the zinc electrode.

Think About It

1. Observe Describe the sensation you felt on your tongue.

2. Measure What was the voltage of your battery? What would happen if you attached the positive lead of the multimeter to the zinc electrode and the negative lead to the copper electrode?

3. Predict Could you generate enough voltage to start a car if you connected 12 lemon batteries together in series? Explain.

21st Century Learning The following project helps students build the following 21st Century Skills: *Global Awareness; Financial, Economic, Business and Entrepreneurial literacy; Civic Literacy; Critical Thinking and Problem Solving; Information, Communications and Technology Literacy.*

GREEN BATTERIES Pose the following challenge to your students. *A company you work for has decided to invest in developing a line of batteries that are better for the environment. Your job is to design an environmentally-friendly 1.5-V battery and develop a presentation promoting your design to the company president.* Designs should include information on materials used for construction, equations for half-cell reactions, calculations of reduction potentials showing that the choice of materials for the electrodes will provide an $E^{\circ}_{cell} = 1.5$ V, and an estimate of the expected life of the battery. An environmental impact statement should be included that compares the potential impact of the battery to that of current batteries.

21.3 Electrolytic Cells

CHEMISTRY & YOU

Q: *How can an aluminum bottle be colored?* You probably know that aluminum is a metal that is silver in color. How then can objects made from aluminum be colored? If an aluminum object has a color other than silver, it was anodized before it was dyed. In the anodizing process, the aluminum object is the anode in an electrolytic cell. The electrolyte is a dilute acid. When an electric current flows through the cell, aluminum oxide forms on the surface of the aluminum. In this lesson, you will learn about electrochemical processes that require electrical energy.

Key Questions

- *How do voltaic and electrolytic cells differ?*
- *What are some applications that use electrolytic cells?*

Vocabulary

- electrolysis
- electrolytic cell

Electrolytic vs. Voltaic Cells

How do voltaic and electrolytic cells differ?

In Lesson 21.1, you learned how a spontaneous chemical reaction can be used to generate a flow of electrons (an electric current). In this lesson, you will learn how an electric current can be used to make a nonspontaneous redox reaction occur. The process in which electrical energy is used to bring about such a chemical change is called **electrolysis.** Although you may not have realized it, you are already familiar with some results of electrolysis, such as gold-plated jewelry and chrome-plated automobile parts. Figure 21.10 shows some silver-plated dishes.

The apparatus in which electrolysis is carried out is an electrolytic cell. An **electrolytic cell** is an electrochemical cell used to cause a chemical change through the application of electrical energy. An electrolytic cell uses electrical energy (direct current) to make a nonspontaneous redox reaction proceed to completion.

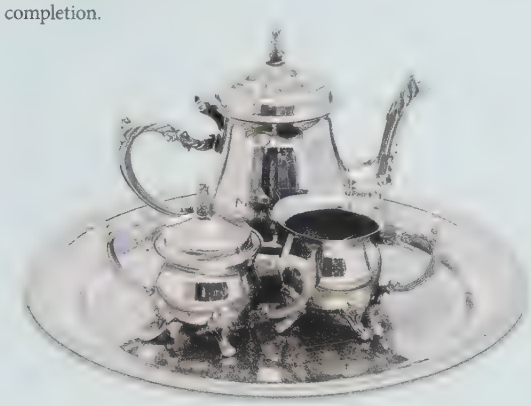


Figure 21.10
Products of Electrolysis
Pure silver can be plated onto steel using electrolysis.

Focus on ELL

1 CONTENT AND LANGUAGE Write the following terms on the board: *apparatus, brine, circuit,* and *net result*. Pronounce each word and ask students to repeat. Clarify the part of speech and discuss any cognates. Have students look up the definitions and add them to their notebooks.

2 FRONTLOAD THE LESSON Display a variety of metal items, which have been plated using either a voltaic or an electrolytic process. Provide information about the base metal and the plating metal of each item. Allow students to examine the objects and predict which ones were plated spontaneously and which ones required energy for plating to occur. Encourage students to refer back to Table 21.1 as they make their predictions.

3 COMPREHENSIBLE INPUT Project Figure 21.11 on the board, and circle the similarities between the two cells as students identify them. Use a different color to circle the differences. Then, have students view the Kinetic Art animation of this figure.

Key Objectives

21.3.1 DISTINGUISH between electrolytic and voltaic cells.

21.3.2 DESCRIBE some applications that use electrolytic cells.

Engage

CHEMISTRY & YOU Have students study the photograph and read the opening text. If possible, display a colored aluminum sport bottle. **Ask** Based on what you just read, do you think anodization is a spontaneous reaction? Why? *(No, it requires an input of electrical energy.)* **Ask** Do you think anodization takes place in a voltaic cell? Why? *(No, because reactions in voltaic cells are spontaneous.)* Tell students to keep this in mind as they proceed with the lesson.

Activate Prior Knowledge

Review the characteristics of voltaic and electrochemical cells with students. Then, create a compare/contrast table for voltaic and electrolytic cells, and fill in the information for voltaic cells. Have students complete the table during the lesson.

Answers

1. a tingling sensation
2. about 1 V; A voltage would not be generated.
3. Yes, any 12-V battery can start a car.

Foundations for Reading

BUILD VOCABULARY *Electr-* and *electro-* are combining forms from the New Latin word *electricus.* Ask students what words they know outside of chemistry that contain these combining forms. *(electricity, electrocardiogram, electronic, electromagnet)*

READING STRATEGY Before beginning this section, have students preview it by leafing through the pages and reading the headings.
Then, have students read the boldface sentences under each heading. Ask them if they now have an idea of what this section is about.

Explain

Electrolytic vs. Voltaic Cells

MAKE A CONNECTION The spontaneous cell reaction in a lead-storage battery provides immediate energy to start a car. **Ask** What reaction is occurring in a car battery that makes it function? *(Lead and lead(IV) oxide undergo a redox reaction in which lead(II) sulfate is formed.)* Students may have experienced a dead battery. Often, recharging can revive a dead battery. **Ask** What reaction occurs during recharging? *(Lead(II) ions in lead(II) sulfate are oxidized to lead(IV) and reduced to lead.)* Point out that until now it has been assumed that reactions in standard half-cells always go in the spontaneous direction. Explain that recharging the car battery is a nonspontaneous reaction that requires energy from another source.

APPLY CONCEPTS Tell students that electrolytic processes are used to separate active metals such as aluminum, magnesium, and sodium from their salts. Explain that this same process is used to recover metals from ores. As a class, compare electrolytic cells to voltaic cells. Point out that in both, oxidation occurs at the anode and reduction at the cathode. Show students that in the voltaic cell, a spontaneous redox reaction occurs, whereas in the electrolytic cell, external electrical energy makes a nonspontaneous redox reaction occur.

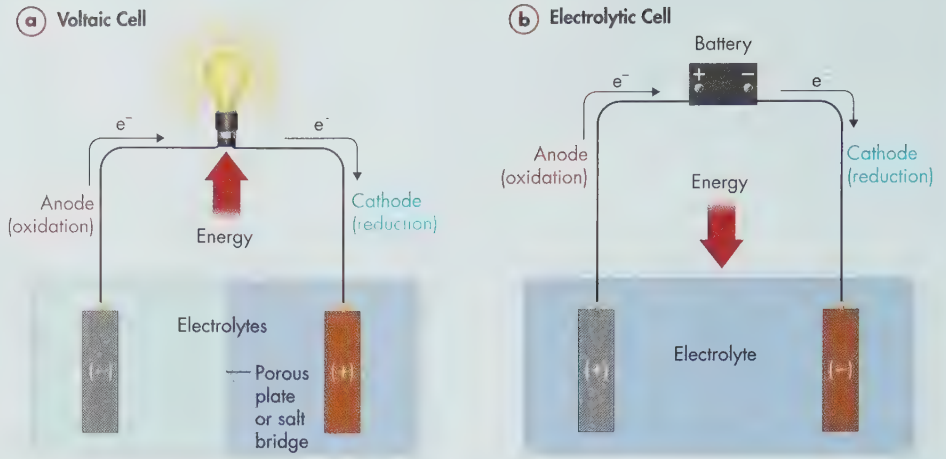

Figure 21.11 Voltaic and Electrolytic Cells Electrochemical cells can be classified as voltaic or electrolytic. **a.** In a voltaic cell, energy is released from a spontaneous redox reaction. The system (cell) does work on the surroundings (light bulb). **b.** In an electrolytic cell, energy is absorbed to drive a nonspontaneous reaction. The surroundings (battery or power supply) do work on the system (cell).

In both voltaic and electrolytic cells, electrons flow from the anode to the cathode in the external circuit. As shown in Figure 21.11, for both types of cells, the electrode at which reduction occurs is the cathode. The electrode at which oxidation occurs is the anode.

The key difference between voltaic and electrolytic cells is that in a voltaic cell, the flow of electrons is the result of a spontaneous redox reaction, whereas in an electrolytic cell, electrons are caused to flow by an outside power source, such as a battery. The redox process in the voltaic cell is spontaneous; in the electrolytic cell, the redox process is nonspontaneous. Electrolytic and voltaic cells also differ in the assignment of charge to the electrodes. In a voltaic cell, the anode is the negative electrode and the cathode is the positive electrode. In an electrolytic cell, the cathode is considered to be the negative electrode because it is connected to the negative electrode of the battery. The anode in the electrolytic cell is considered to be the positive electrode because it is connected to the positive electrode of the battery. It is important to remember these conventions about the two kinds of cells.

Driving Nonspontaneous Processes

What are some applications that use electrolytic cells?

Electrolysis can be used to drive otherwise nonspontaneous reactions that are of commercial importance. **Electrolysis of a solution or of a melted, or molten, ionic compound can result in the separation of elements from compounds. Electrolytic cells are also commonly used in the plating, purifying, and refining of metals.**

Anodizing

Anodizing is an electrolytic process for applying a corrosion-resistant oxide coating to aluminum and certain other metals. When an electric current flows through an electrolytic cell containing an aluminum anode, a thin coat of aluminum oxide forms on the surface of the aluminum. Immersion of the aluminum object in pure boiling water permanently seals the film against corrosion. Dyeing of anodized aluminum can produce metallic red, metallic blue, and a host of other metallic colors on the metal surface. Also, the high porosity of the oxide coating permits it to absorb pigments and lubricants.

746 Chapter 21 • Lesson 3

Electrolysis of Water When a current is applied to two electrodes immersed in pure water, nothing happens. There is no current flow and no electrolysis. However, when an electrolyte such as H_2SO_4 or KNO_3 in low concentration is added to the pure water, the solution conducts an electric current and electrolysis occurs. This process is illustrated in Figure 21.12. The products of the electrolysis of water are hydrogen gas and oxygen gas. This process is sometimes used to produce hydrogen gas for fuel cells.

Water is oxidized at the anode according to the following oxidation half-reaction:

$$\text{Oxidation:}\quad 2H_2O(l) \longrightarrow O_2(g) + 4H^+(aq) + 4e^- \text{ (at anode)}$$

Water is reduced to hydrogen at the cathode according to the following reduction half-reaction:

$$\text{Reduction:}\quad 2H_2O(l) + 2e^- \longrightarrow H_2(g) + 2OH^-(aq) \text{ (at cathode)}$$

The region around the anode turns acidic due to an increase in H^+ ions. The region around the cathode turns basic due to the production of OH^- ions. The overall cell reaction is obtained by adding the half-reactions (after doubling the reduction half-reaction equation to balance electrons).

$$\text{Oxidation:}\quad 2H_2O(l) \longrightarrow O_2(g) + 4H^+(aq) + 4e^-$$

$$\text{Reduction:}\quad 2[2H_2O(l) + 2e^- \longrightarrow H_2(g) + 2OH^-(aq)]$$

$$\text{Overall cell reaction:}\quad 6H_2O(l) \longrightarrow 2H_2(g) + O_2(g) + 4H^+(aq) + 4OH^-(aq)$$

The ions produced tend to recombine to form water.

$$4H^+(aq) + 4OH^-(aq) \longrightarrow 4H_2O(l)$$

Therefore, the net reaction can be written as follows:

$$2H_2O(l) \longrightarrow 2H_2(g) + O_2(g)$$

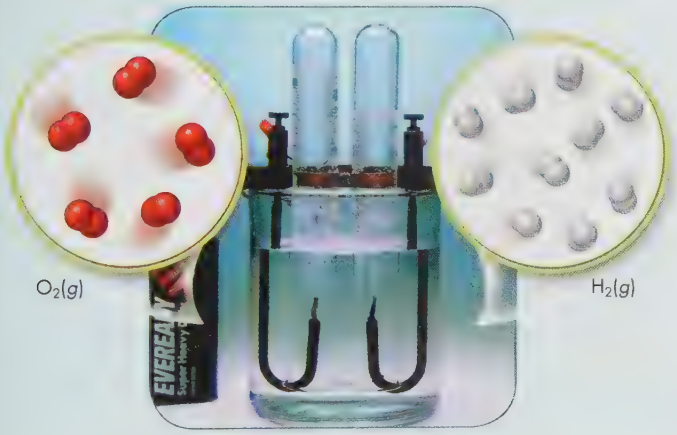

Figure 21.12 Electrolysis of Water When an electric current is passed through water, the water decomposes into oxygen gas and hydrogen gas.
Interpret Photos *Which electrode in the photograph is the cathode? Which is the anode?*

UbD Check for Understanding

How do voltaic and electrolytic cells differ?

Have students answer the key question by briefly summarizing the similarities and differences between the two cells with a compare/contrast statement.

ADJUST INSTRUCTION If students are having difficulty writing their statements, have them examine Figure 21.11 and identify the similarities and differences. Then, reinforce the concept that voltaic cell reactions are spontaneous, while those that take place in electrolytic cells do so only when an input of energy occurs.

Explain

Driving Nonspontaneous Processes

USE VISUALS Direct students' attention to Figure 21.12. Call attention to the volumes of hydrogen and oxygen that have been collected in the photograph. **Ask** Why is one volume larger than the other? *(When water is decomposed, two molecules of hydrogen are formed for every one molecule of oxygen.)* For emphasis, write the equation for the decomposition of water on the board. **Ask** Why is it necessary to add an acid to the water in the cell? *(Water is a molecular compound; it does not form a significant number of ions. The liquid in the cell must be an electrolyte, that is, it must contain ions.)*

Explore

Teacher Demo

PURPOSE Students will observe the electrolysis of water and note that energy is required for the process.

MATERIALS Hoffman apparatus or construct a substitute using iron nails as electrodes, 2 test tubes, 6*M* NaOH, 250- or 500-mL beaker, 2 insulated wires

SAFETY Wear gloves, apron and safety goggles. NaOH is corrosive.

PROCEDURE If you have sufficient class time, assemble the apparatus in front of the class. Otherwise, prepare the apparatus in advance. Insert the iron electrodes into the lower ends of the test tubes. Use insulated wires to connect the electrodes to a power supply to avoid contact with the electrolyte. Fill the test tubes with the NaOH solution and invert them in a beaker that is one-third filled with the solution. When all is ready, turn on the power supply.

EXPECTED OUTCOMES Hydrogen gas is collected at the negative electrode (cathode); oxygen gas is collected at the positive electrode (anode). Demonstrate with a lit match (H_2) and a glowing splint (O_2) that one test tube contains hydrogen and the other oxygen.

Answers

Figure 21.12 The electrode on the right is the cathode; the electrode on the left is the anode.

Explain

USE VISUALS Have students study the diagram in Figure 21.13. **Ask** What is the purpose of the battery? *(The battery is a voltaic cell that supplies the electrical energy needed to drive the nonspontaneous redox reaction in the electrolytic cell.)* **Ask** What substance is being oxidized in the electrolytic cell? *(Cl^-)* **Ask** What substance is being reduced? *(H_2O)*

START A CONVERSATION Explain that AC current alternates, meaning that it flows in both directions around a circuit (unless the circuit has diodes), and that in DC current, electric current flows in one direction only. Refer students to Figure 21.13. **Ask** Why is DC current, and not AC current, used to run the reaction? *(DC devices maintain a constant potential difference. The voltage potential from an AC generator alternates in sign.)* Write the overall equation for the reaction on the board and ask students to use the standard reduction potentials in Table 21.2 to show why this reaction is nonspontaneous. [$Cl_2(g) + 2e^- \rightarrow 2Cl^-(aq)$; $E° = +1.36$ V

$2H_2O(l) + 2e^- \rightarrow H_2(g) + 2OH^-(aq)$; $E° = -0.42$ V

$E°_{cell} = E°_{red} - E°_{oxid} = -0.42\text{ V} - 1.36\text{ V} = -1.78$ V

The potential is negative; therefore, energy is needed to make this reaction occur.]

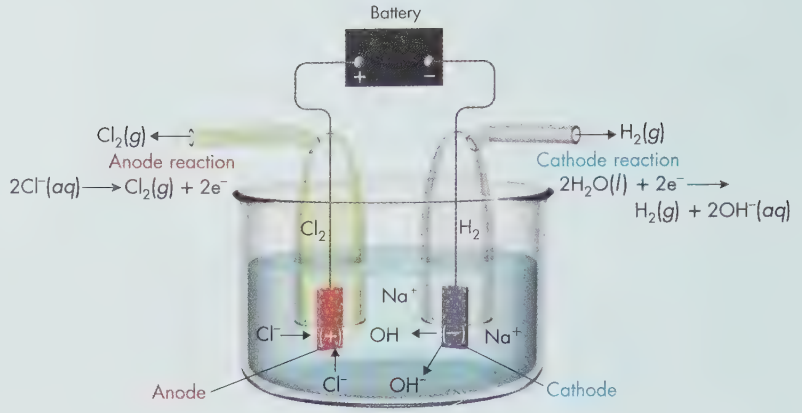

Figure 21.13 Electrolysis of Brine
Chlorine gas, hydrogen gas, and sodium hydroxide are produced when an electric current is passed through an aqueous solution of sodium chloride.
Interpret Diagrams ***Which substances are produced by oxidation? Which substances are produced by reduction?***

Electrolysis of Brine If the electrolyte in an aqueous solution is more easily oxidized or reduced than water, then the products of electrolysis will be substances other than hydrogen and oxygen. An example is the electrolysis of brine, a concentrated aqueous solution of sodium chloride. This process simultaneously produces three important industrial chemicals: chlorine gas, hydrogen gas, and sodium hydroxide. The electrolytic cell for the electrolysis of brine is shown in Figure 21.13.

During electrolysis of brine, chloride ions are oxidized to produce chlorine gas at the anode. Water is reduced to produce hydrogen gas at the cathode. Sodium ions are not reduced to sodium metal in the process because water molecules are more easily reduced than are sodium ions. The reduction of water also produces hydroxide ions. Thus, the electrolyte in solution becomes sodium hydroxide (NaOH). The half-reactions are as follows:

Oxidation: $2Cl^-(aq) \longrightarrow Cl_2(g) + 2e^-$ (at anode)

Reduction: $2H_2O(l) + 2e^- \longrightarrow H_2(g) + 2OH^-(aq)$ (at cathode)

The overall ionic equation is the sum of the two half-reactions.

$$2Cl^-(aq) + 2H_2O(l) \longrightarrow Cl_2(g) + H_2(g) + 2OH^-(aq)$$

The spectator ion Na^+ can be included in the equation (as part of NaCl and of NaOH) to show the formation of sodium hydroxide during the electrolytic process.

$$2NaCl(aq) + 2H_2O(l) \longrightarrow Cl_2(g) + H_2(g) + 2NaOH(aq)$$

When the sodium hydroxide solution is about 10 percent (mass/volume), it is removed from the cell and processed further.

Differentiated Instruction

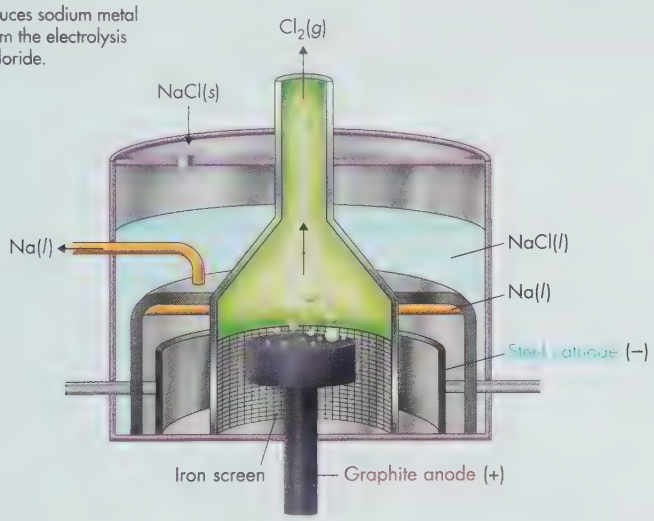
L3 ADVANCED STUDENTS Explain that electrolytic cells are used in the recovery of low-grade ores in mining. Have students select a metal and research how it is recovered and purified by electrolysis.

L1 LESS PROFICIENT READERS Make a sketch of the cell in Figure 21.13 on the board. Use different colors to label the cathode (1) and anode (2) on the battery. Use gestures to show the flow of electrons from the anode (negative terminal) of the battery to the cathode (negative electrode) of the electrolytic cell, and from the anode (positive electrode) of the electrolytic cell to the cathode (positive terminal) of the battery. Emphasize that in both the voltaic and electrolytic cells, the definitions of a cathode and an anode are the same: reduction always takes place at the cathode and oxidation always takes place at the anode.

ELL ENGLISH LANGUAGE LEARNERS Explain that AC current is an abbreviation for alternating current, and that DC current is an abbreviation for direct current.

Electrolysis of Molten Sodium Chloride Both sodium and chlorine are commercially important. Sodium is used in sodium vapor lamps and as the coolant in some nuclear reactors. Chlorine, a greenish-yellow gas, is used to sterilize drinking water and is important in the manufacture of polyvinyl chloride (PVC) and various pesticides. These two elements are produced through the electrolysis of pure molten sodium chloride, rather than an aqueous solution of NaCl. Chlorine gas is produced at the anode, and molten sodium collects at the cathode. The half-reactions for the electrolysis of molten sodium chloride are as follows:

Oxidation: $2Cl^-(l) \longrightarrow Cl_2(g) + 2e^-$ (at anode)



Reduction: $2Na^+(l) + 2e^- \longrightarrow 2Na(l)$ (at cathode)

The overall equation is the sum of the two half-reactions.

$$2NaCl(l) \longrightarrow 2Na(l) + Cl_2(g)$$

The electrolytic cell in which this commercial process is carried out is called the Downs cell and is shown in Figure 21.14. The cell operates at a temperature of 801°C so that the sodium chloride is maintained in the molten state. A perforated iron screen separates the circular cathode from the graphite anode. The sodium, with a melting point of 97.8°C, remains in liquid form. The liquid sodium floats on the more dense molten sodium chloride and is drawn off as it is formed. The chlorine gas is collected after it bubbles up and out of the molten salt. The design of the Downs cell allows fresh sodium chloride to be added as required. The design also separates the products so they will not recombine to re-form sodium chloride.

Figure 21.14 Downs Cell
The Downs cell produces sodium metal and chlorine gas from the electrolysis of molten sodium chloride.

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in small groups to complete the Small-Scale Lab on page 752. Make sure each pairing has ELLs of varied language proficiencies, so that a more proficient student can help a less proficient one. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Model this lab for these students. Use think-aloud and gestures during the demonstrations. Pause and have students mimic you as you move through the procedure.

INTERMEDIATE: LOW/HIGH Restate the steps in simpler terms. Allow students to present their results orally.

ADVANCED: LOW/HIGH Ask students to present to the class their analysis of the experiment and how they used what they learned to design the experiment described in #3 of You're the Chemist.

CRITICAL THINKING Note that metallic sodium has a much lower melting point than sodium chloride. **Ask** How are the two substances different? *(Metallic sodium is an element in its pure form, while sodium chloride is an ionic compound.)* **Ask** What type of intermolecular forces hold the ions in NaCl crystals together? *(the attraction between the positively charged sodium ions and the negatively charged chloride ions)* Point out that this is an electrostatic attraction. Explain that the atoms in a metal are also held in place in their crystal lattice by electrostatic attractions. Because metals so readily give up electrons to form ions, the positively charged sodium ions are surrounded by a so-called "sea" composed of the electrons that were given up by the atoms in forming the sodium ions. These electrons form electrostatic attractions with the sodium ions in the lattice. **Ask** How can the melting points of metallic sodium and NaCl be so different when their crystals are both held together by electrostatic attractions? *(The electrostatic attraction between sodium and chloride ions must be greater than the electrostatic attraction between sodium ions and individual electrons, so a greater input of energy is required to disrupt the attraction between the sodium and chloride ions.)*

Extend

Connect to ENVIRONMENTAL SCIENCE

Explain that the need for metallic sodium has decreased since gasoline engines changed to unleaded fuel. Have students determine the relationship between metallic sodium and unleaded gasoline and explain the environmental concerns associated with its use.

Answers

FIGURE 21.13 Oxidation produces chlorine gas. Reduction produces hydrogen gas and hydroxide ions.

Explore

QuickLab

OBJECTIVE Students electrochemically oxidize metals and identify the products.

SKILLS FOCUS observing, inferring

PREP TIME 15 minutes

CLASS TIME 20 minutes

MATERIALS 9-volt battery, copper penny, nickel coin, iron nail, filter paper, aluminum foil, reaction surface, Na_2SO_4

ADVANCE PREPARATION

Solution	Preparation
0.2*M* Na_2SO_4	7.1 g in 250 mL water

EXPECTED OUTCOMES In Step 3, a light blue image of the penny appears on the filter paper. In Step 4, a blue-green image of the nickel appears. In Step 5, a brownish-red image of the nail appears.

ANALYZE AND CONCLUDE

1. See Expected Outcomes.
2. Each oxidation occurs at the anode:
   $Cu(s) \rightarrow Cu^{2+}(aq) + 2e^-$
   $Ni(s) \rightarrow Ni^{2+}(aq) + 2e^-$
   $Fe(s) \rightarrow Fe^{2+}(aq) + 2e^-$
3. The battery oxidized each metal, and the resulting colored metal ion migrated to the filter paper.
4. $H_2O(l) + 2e^- \rightarrow \frac{1}{2} H_2O(g) + OH^-(aq)$
5. $H_2O(l) + 2e^- \rightarrow \frac{1}{2} H_2(g) + OH^-(aq)$
   $Cu(s) \rightarrow Cu^{2+}(aq) + 2e^-$
   $H_2O(l) + Cu(s) \rightarrow \frac{1}{2} H_2(g) + OH^-(aq) + Cu^{2+}(aq)$

FOR ENRICHMENT Have students repeat Steps 1–3 but replace $Na_2SO_4(aq)$ with one drop of 0.1*M* KI and one drop of 20% (v/v) starch solution. Explain that the battery oxidized the iodide ions to form iodine. Ask students to write a half-reaction for the oxidation and explain the color change. *($2I^- \rightarrow I_2 + 2e^-$; I^- ions are oxidized to I_2, which reacts with starch to form a blue-black substance.)*

QuickLab

Electrochemical Analysis of Metals

Purpose To electrochemically oxidize metals and identify the products

Materials

- reaction surface
- aluminum foil
- filter paper
- micropipette or dropper
- sodium sulfate (Na_2SO_4) solution
- penny
- 9-volt battery
- nickel coin
- iron nail

Procedure

1. Stack the following in order on a reaction surface: a 3-cm square of aluminum foil, a 2-cm square of filter paper, 1 drop of Na_2SO_4 solution, and a penny. The penny should be roughly centered on the filter paper, which should be roughly centered on the foil.
2. Apply the negative (−) terminal of the 9-volt battery to the aluminum foil and the positive (+) terminal to the penny for no more than three seconds.
3. Remove the penny and observe the filter paper.
4. Repeat Steps 1–3, replacing the penny with the nickel coin.
5. Repeat Steps 1–3, replacing the penny with the iron nail.

Analyze and Conclude

1. **Observe** What colors formed on the filter paper for each object?
2. **Describe** For each metal object you tested, the battery oxidized the metal atoms to form metal cations with a 2+ charge. Write a half-reaction for each metal oxidation you observed. Did these reactions take place at the anode or the cathode?
3. **Relate Cause and Effect** Explain in your own words why the colors formed on the filter paper.
4. **Describe** The aluminum foil serves as the cathode, where the reduction of water takes place. Write the half-reaction for the reduction of water.
5. **Describe** Combine the half-reaction for the oxidation of copper with the half-reaction for the reduction of water to form the overall equation for the cell reaction.

Using Electrolysis in Metal Processing Electrolysis has many important applications in the field of metallurgy. Many of the shiny, metallic objects you see every day—such as chrome-plated fixtures or nickel-plated coins—were manufactured with the help of electrolytic processes.

Electroplating and Electroforming Electroplating is the deposition of a thin layer of a metal on an object in an electrolytic cell. An object may be electroplated to protect the surface of the base metal from corrosion or to make it more attractive. An object that is to be silver-plated is made the cathode in an electrolytic cell. The anode is the metallic silver that is to be deposited, and the electrolyte is a solution of a silver salt, such as silver cyanide. When a direct current is applied, silver ions move from the anode to the object to be plated.

Reduction: $Ag^+(aq) + e^- \longrightarrow Ag(s)$ (at cathode)

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the lab. Make sure each group has ELLs of varied language proficiencies, so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Paraphrase orally the procedural steps and group students with higher language proficiency partners.

INTERMEDIATE: LOW/HIGH Have students brainstorm what they think they may observe, prior to performing each step. Allow students to orally present their results.

ADVANCED: LOW/HIGH Have students model the procedures for group members and then assist the group as they repeat the procedure using the nickel coin and the iron.

The net result is that silver transfers from the silver anode to the object being plated. Figure 21.15 shows statuettes that were electroplated with copper, nickel, and 24-carat gold. Many factors contribute to the quality of the metal coating that forms. In the plating solution, the concentration of the cations to be reduced must be carefully controlled. The solution must also contain compounds to control the acidity and to increase the conductivity. Other compounds may be used to make the metal coating brighter or smoother.

Electroforming is a process in which an object is reproduced by making a metal mold of it at the cathode of a cell. For example, a mold of an object can be coated with metal so it will conduct a current. It is then electroplated with a thick coating of metal. This coating can then be stripped off of the mold. Electroforming is used to make jewelry and tubing for chemical instrumentation, such as gas chromatographs.

Figure 21.15 Electroplating Copper, nickel, and gold were electroplated onto pewter to produce these statuettes.

Electrowinning and Electrorefining In a process called electrowinning, impure metals can be purified in electrolytic cells. The cations of molten salts or aqueous solutions are reduced at the cathode to give very pure metals. A common use of electrowinning is in the extraction of aluminum from its ore, bauxite. Bauxite is impure alumina (Al_2O_3). In a method known as the Hall-Heroult process, purified alumina is dissolved in molten cryolite (Na_3AlF_6), and heated to above 1000°C in a carbon-lined tank. The carbon lining, connected to a direct current, serves as the cathode. The anode consists of carbon rods dipped into the tank. At the cathode, Al^{3+} ions are reduced, forming molten aluminum. At the anode, carbon is oxidized, forming carbon dioxide gas. The overall reaction is as follows:

$$2Al_2O_3(l) + 3C(s) \longrightarrow 4Al(l) + 3CO_2(g)$$

In the process of electrorefining, a piece of impure metal is made the anode of the cell. It is oxidized to the cation and then reduced to the pure metal at the cathode. This technique is used to obtain ultrapure silver, lead, and copper.

Other Processes Other electrolytic processes are centered on the anode rather than the cathode. In electropolishing, for example, the surface of an object at the anode is dissolved selectively to give it a high polish. In electromachining, a piece of metal at the anode is partially dissolved until the remaining portion is an exact copy of the object at the cathode.

CHEMISTRY & YOU

Q: *In the process of anodizing aluminum, the aluminum object serves as the anode. To which electrode of the power source is the anode connected?*

21.3 LessonCheck

20. Describe What is the difference between an electrolytic cell and a voltaic cell?

21. List What are some applications of electrolytic cells?

22. Compare What is the charge on the anode of an electrolytic cell? What is the charge on the anode of a voltaic cell?

23. Apply Concepts Which process, oxidation or reduction, always occurs at the cathode of an electrolytic cell?

24. Explain Read about the Hall-Heroult process on page R13. Write the half-reactions for the electrolysis that takes place, and explain the function of cryolite in the process.

BIG IDEA MATTER AND ENERGY

25. Does the redox reaction in a voltaic cell release free energy? If no electrical energy is supplied, does the redox reaction in an electrolytic cell release free energy? Explain.

Lesson Check Answers

20. A voltaic cell uses an electrochemical reaction to produce electrical energy; an electrolytic cell uses electrical energy to bring about a chemical change.

21. to separate elements from compounds and to plate, purify, and refine metals

22. electrolytic cell anode (+); voltaic cell anode (–)

23. Reduction always occurs at the cathode.

24. Anode: $C(s) + 2O^{2-}(l) \rightarrow CO_2(g) + 4e^-$
Cathode: $3e^- + Al^{3+}(l) \rightarrow Al(l)$
Adding cryolite to aluminum oxide results in a mixture that melts at a much lower temperature (1012°C) than pure aluminum oxide (2045°C).

25. Yes, the electrical energy produced in a voltaic cell can do work. An electrolytic cell does not produce free energy unless an electrical current is supplied.

Extend

Connect to METALLURGY

Explain that gold and silver are the most common metals used for plating jewelry. Have students research how electrolysis is used in plating jewelry and share their findings with the class. *(A thin layer of the precious metal is deposited over much less expensive base metals such as copper. Nonmetallic objects may be used as the base material as long as their surface is first coated with a conductor such as graphite. Plating solutions contain a suitable electrolyte (an acid or base) to adjust pH. Small amounts of other substances may be added to vary the color of gold jewelry. Nickel, silver, copper, cobalt, and iridium may be deposited along with the gold.)*

Evaluate

Informal Assessment

Have students draw and label a simple electrolytic cell for the hydrolysis of water. Students should include labels for the cathode, anode, and the positive and negative terminals of the battery, as well as indicate the paths of electrons, hydroxide ions, and hydrogen ions between the anode and the cathode.

Then, direct students to complete 21.3 Lesson Check.

Reteach

Use the diagrams in this lesson as a basis for review. Starting with Figure 21.11 and continuing to Figure 21.14, question students about what is being illustrated and what is significant about it.

Then, direct students to study the voltaic and electrolytic cells compare/contrast chart they created. Have students add to this chart or clear up any misconceptions.

Small-Scale Lab

OBJECTIVE Students electrolyze solutions and interpret their observations.

SKILLS FOCUS observing, drawing conclusions

MATERIALS reaction surface, electrolysis device, reagents listed below

PREP TIME 30 minutes

CLASS TIME 30 minutes

ADVANCE PREPARATION

Solution	Preparation
0.2*M* Na_2SO_4	7.1 g in 250 mL
0.1*M* KI	4.2 g in 250 mL
0.2*M* $CuSO_4$	12.5 g $CuSO_4 \cdot 5H_2O$ in 250 mL
Starch	50 mL liquid starch in 200 mL
0.04% BTB	100 mg in 16.0 mL of 0.01M NaOH; dilute to 250 mL
1.0*M* NaCl	14.6 g in 250 mL
0.2*M* KBr	6.0 g in 250 mL

EXPECTED OUTCOMES

Figure A *H_2O:* no visible reaction; *Na_2SO_4:* bubbles at anode and cathode; *Na_2SO_4 + BTB:* anode yellow, cathode blue.

Figure B *KI:* bubbles at cathode, yellow solution at anode; *KI + starch:* bubbles at cathode, black solution at anode; *KI + BTB:* bubbles and blue solution at cathode, yellow solution at anode.

ANALYZE AND CONCLUDE

1. Pure water has too few ions to carry an electric current.
2. In solution, sodium sulfate dissociates into ions, which carry an electric current.
3. The bubbles are $H_2(g)$, and the blue BTB solution indicates the presence of OH^- ions.
4. The bubbles are $O_2(g)$, and H^+ ions in solution impart the yellow color to the BTB solution.
5. $H_2O(l) \rightarrow H_2(g) + \frac{1}{2}O_2(g)$

YOU'RE THE CHEMIST

1. Bubbles are $H_2(g)$; blue solution indicates presence of OH^- ions; yellow solution is $I_2(aq)$, which is black in the presence of starch.
2. I^- is more likely to oxidize than H_2O because it has a more positive $E°$ value:
   $H_2O(l) \rightarrow \frac{1}{2}O_2(g) + 2H^+ + 2e^-$; $E° = -0.82$ V
   $2I^-(aq) \rightarrow I_2(aq) + 2e^-$; $E° = -0.54$ V
3. **NaCl** Cathode: $2H_2O(l) + 2e^- \rightarrow H_2(g) + 2OH^-(aq)$ (bubbles, blue BTB); Anode: $2Cl^-(aq) \rightarrow Cl_2(aq) + 2e^-$ (yellow solution)
   KBr Cathode: $2H_2O(l) + 2e^- \rightarrow H_2(g) + 2OH^-(aq)$ (bubbles, blue BTB); Anode: $2Br^-(aq) \rightarrow Br_2(aq) + 2e^-$ (yellow solution)
   $CuSO_4$ Cathode: $Cu^{2+} + 2e^- \rightarrow H_2(g) + 2OH^-(aq)$ (copper plates out);
   Anode: $H_2O(l) \rightarrow \frac{1}{2}O_2(g) + 2H^+(g) + 2e^-$
   (bubbles, yellow BTB)

Small-Scale Lab

Electrolysis of Water

Purpose

To electrolyze solutions and interpret your observations in terms of chemical reactions and equations

Materials

- reaction surface
- micropipettes or droppers
- electrolysis device
- water
- sodium sulfate (Na_2SO_4) solution
- bromothymol blue (BTB) solution

Procedure

1. On separate sheets of paper, draw two grids similar to Figure A. Make each square 2 cm on each side.
2. Place a reaction surface over one of the grids and add one drop of each solution shown in Figure A.
3. Apply the leads of the electrolysis device to each solution. Be sure to clean the leads between each experiment. Look carefully at the cathode (negative lead) and the anode (positive lead).
4. Use the second grid as a data table to record your observations for each solution.

H_2O	Na_2SO_4	Na_2SO_4 + BTB

Figure A

Analyze and Conclude

1. **Relate Cause and Effect** Explain why pure water does not conduct an electric current and does not undergo electrolysis.
2. **Relate Cause and Effect** Explain why water with sodium sulfate conducts an electric current and undergoes electrolysis.
3. **Analyze Data** The cathode provides electrons to water, and the following half-reaction occurs:
   $2H_2O(l) + 2e^- \longrightarrow H_2(g) + 2OH^-(aq)$
   Explain how your observations correspond to the products shown in this reaction.
4. **Analyze Data** The anode removes electrons from water, and the following half-reaction occurs:
   $H_2O(l) \longrightarrow \frac{1}{2}O_2(g) + 2H^+(aq) + 2e^-$
   Explain how your observations correspond to the products shown in this reaction.
5. **Summarize** Add the two half-reactions to obtain the overall reaction for the electrolysis of water. Simplify the result by adding the OH^- and H^+ ions to get H_2O, and then canceling anything that appears on both sides of the equation.

You're the Chemist

1. **Analyze Data** Perform the above experiment using the solutions shown in Figure B. Record your results. The cathode and anode reactions are
   $2H_2O(l) + 2e^- \longrightarrow H_2(g) + 2OH^-(aq)$ (at cathode)
   $2I^-(aq) \longrightarrow I_2(aq) + 2e^-$ (at anode)
   Explain how your observations correspond to the products shown in these half-reactions.

KI	KI + starch	KI + BTB

Figure B

2. **Analyze Data** For each half-reaction listed above, look up the $E°$ values in Table 21.2. Show that the $E°$ values are consistent with what you observe.
3. **Design an Experiment** Design an experiment to explore what happens when you electrolyze NaCl, KBr, and $CuSO_4$ with and without BTB. Write half-reactions to predict your results.

FOR ENRICHMENT In 1985, treasure hunter Mel Fisher salvaged tons of silver coins from the shipwrecked galleon *Atocha*, which sank in 1622. Have students research the electrochemistry Fisher used to rescue the treasure from corrosion.

21 Study Guide

BIGIDEA MATTER AND ENERGY

The two types of electrochemical cells are voltaic cells and electrolytic cells. In a voltaic cell, electric current is produced by a spontaneous redox reaction. Voltaic cells are used in batteries and fuel cells. In an electrolytic cell, a nonspontaneous redox reaction is driven by the application of electrical energy. Electrolytic cells are used to produce commercially important chemicals and to plate, purify, and refine metals.

21.1 Electrochemical Cells

- All electrochemical processes involve redox reactions.
- Electrical energy is produced in a voltaic cell by a spontaneous redox reaction within the cell.
- Current applications that use electrochemical processes to produce electrical energy include dry cells, lead storage batteries, and fuel cells.

- electrochemical process (728)
- electrochemical cell (730)
- voltaic cell (730)
- half-cell (730)
- salt bridge (730)
- electrode (730)
- anode (730)
- cathode (730)
- dry cell (732)
- battery (733)
- fuel cell (734)

21.2 Half-Cells and Cell Potentials

- The electrical potential of a cell results from a competition for electrons between two half-cells.
- You can determine the standard reduction potential of a half-cell by using a standard hydrogen electrode and the equation for standard cell potential.
- If the cell potential for a given redox reaction is positive, then the reaction is spontaneous as written. If the cell potential is negative, then the reaction is nonspontaneous.

- electrical potential (737)
- reduction potential (737)
- cell potential (737)
- standard cell potential (737)
- standard hydrogen electrode (738)

Key Equation

$$E^\circ_{cell} = E^\circ_{red} - E^\circ_{oxid}$$

21.3 Electrolytic Cells

- The key difference between voltaic and electrolytic cells is that in a voltaic cell, the flow of electrons is the result of a spontaneous redox reaction, whereas in an electrolytic cell, electrons are caused to flow by an outside power source, such as a battery.
- Electrolysis of a solution or of a melted, or molten, ionic compound can result in the separation of elements from compounds. Electrolytic cells are also commonly used in the plating, purifying, and refining of metals.

- electrolysis (745)
- electrolytic cell (745)

Review and Assessment Materials

PROBLEM SETS Have students practice more electrochemistry problems by using the Chapter 21 Online Problem Set.

MATH SKILLS REVIEW Have struggling students practice solving algebraic equations by using the MathXL learning module.

Study Tip

Study for short, focused blocks of time. Take a break when you feel tired. When you are no longer being productive, take a short walk or stretch.

STUDY GUIDE

Focus on ELL

5 ASSESS UNDERSTANDING Have students read the Big Idea paragraph aloud to themselves. Have students create a list of words that they cannot pronounce or do not understand. Have students use the lesson review to locate the words in the text so they can define them.

BEGINNING: LOW/HIGH Give each student a copy of the Study Guide. Ask them to make a check mark next to the content they understand and circle the content they do not understand. Create assessments with illustrations and symbols to assess only the content they circle.

INTERMEDIATE: LOW/HIGH Explain the meaning of common words or phrases that appear on multiple choice questions, such as *Which is the most/least likely, or Which best explains, etc.* Orally pose some questions using these phrases.

Understanding by Design

UbD Performance Tasks

ELECTROPLATING Have students work with a partner to research, design, and perform an electroplating demonstration. Students should prepare a report that explains the electrochemical process in their demonstration. The report should include a sketch that identifies the cathode and anode and describe the reactions that occur in each half-cell with the appropriate chemical reactions

EVERYDAY ELECTROCHEMISTRY Have students create a slide-show presentation about everyday examples of electrochemistry. The presentations should explain voltaic cells and electrolytic cells, and it should describe at least two examples of each. Encourage students to include photographs and illustrations in their presentations.

Answers

LESSON 21.1

26. the metal with the higher activity

27. Oxidation: $Al(s) \rightarrow Al^{3+}(aq) + 3e^-$
Reduction: $Cu^{2+}(aq) + 2e^- \rightarrow Cu(s)$

28. **a.** Cu **b.** Ca **c.** Mg **d.** Sn **e.** Zn **f.** Al

29. nothing

30. A half-cell is one part of a voltaic cell in which either oxidation or reduction occurs.

31. The salt bridge allows ions to pass from one half-cell to the other but prevents the solutions from mixing.

32. cathode

33. A zinc container (anode) filled with electrolyte paste; the cathode is a graphite rod embedded in the paste. Zn is oxidized; MnO_2 is reduced.

34. Dry cells and alkaline batteries are both single electrochemical cells that produce about 1.5 V. The two cells share a similar structure (a graphite cathode embedded in an electrolyte paste, with a zinc container that serves as the anode) but use different electrolyte mixtures. Compared to a dry cell, an alkaline battery has a longer shelf life and produces a steadier voltage.

35. Water is produced by the redox reaction and sulfuric acid is used up; water has a lower density than sulfuric acid.

36. $Pb(s)|PbSO_4(aq)||PbO_2(s)|PbSO_4(s)$

37. A fuel cell needs no recharging; it does not produce toxic wastes; and if the fuel is hydrogen gas, it is lighter.

38. Fuel cells cannot generate electricity as economically as more conventional forms of electrical generation.

LESSON 21.2

39. the ability of a voltaic cell to produce a current

40. The standard reduction potential of a half-cell is a measure of the tendency of a given half-reaction to occur as a reduction under standard conditions. The difference between the standard reduction potentials of the two half-cells is the standard cell potential.

41. 0.00 V; the value was set arbitrarily.

42. Connect the aluminum half-cell to a standard hydrogen half-cell and use a voltmeter. The indicated voltage is the standard reduction potential for the aluminum half-cell.

43. The relative order is the same because both tables rank the elements according to their tendency to undergo oxidation/reduction.

44. **a.** nonspontaneous, –0.34 V
b. nonspontaneous, –1.24 V

45. **a.** +1.10 V **b.** +1.61 V **c.** +0.94 V

21 Assessment

* Solutions appear in Appendix E

Lesson by Lesson

21.1 Electrochemical Cells

26. If the relative activities of two metals are known, which metal is more easily oxidized?

27. Write the half-reactions that occur when a strip of aluminum is dipped into a solution of copper(II) sulfate.

***28.** For each pair of metals listed below, decide which metal is more readily oxidized.

a. Hg, Cu
b. Ca, Al
c. Ni, Mg
d. Sn, Ag
e. Pb, Zn
f. Cu, Al

29. What would you expect to happen when a strip of lead is placed in an aqueous solution of magnesium nitrate?

30. What is meant by the term *half-cell*?

31. Explain the function of the salt bridge in a voltaic cell.

32. At which electrode in a voltaic cell does reduction always occur?

***33.** Describe the structure of a dry cell. What substance is oxidized? What substance is reduced?

34. How are dry cells and alkaline batteries similar? How are they different?

35. Explain why the density of the electrolyte in a lead storage battery decreases during the discharge process.

***36.** Use the shorthand method to represent the electrochemical reaction in a lead storage battery.

37. List the advantages of a fuel cell over a lead storage battery.

38. Fuel cells can be designed to generate electrical energy while emitting no air pollutants, yet they are not widely used. Explain.

21.2 Half-Cells and Cell Potentials

39. What is the electrical potential of a voltaic cell?

***40.** What is the difference between standard cell potential and standard reduction potential?

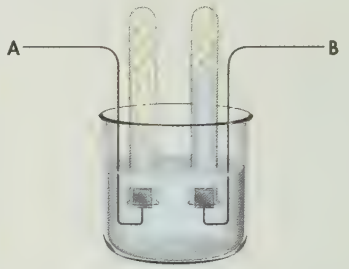
41. What is the electrical potential of a standard hydrogen electrode? How was it determined?

42. Explain how to determine the standard reduction potential for the aluminum half-cell.

43. How does the order of the metals in Table 21.1 compare with the order in Table 21.2? Explain.

***44.** Determine whether these redox reactions will occur spontaneously. Calculate the standard cell potential in each case.

a. $Cu(s) + 2H^+(aq) \longrightarrow Cu^{2+}(aq) + H_2(g)$
b. $2Ag(s) + Fe^{2+}(aq) \longrightarrow 2Ag^+(aq) + Fe(s)$



45. Use the information in Table 21.2 to calculate standard cell potentials for these voltaic cells.

a. $Zn \mid Zn^{2+} \parallel Cu^{2+} \mid Cu$
b. $Ni \mid Ni^{2+} \parallel Cl_2 \mid Cl^-$
c. $Sn \mid Sn^{2+} \parallel Ag^+ \mid Ag$

21.3 Electrolytic Cells

***46.** Distinguish between voltaic and electrolytic cells.

Use the diagram to answer Problems 47–49.

47. Write the equation for the decomposition of water by electrolysis.

48. At which electrode, A or B, is hydrogen produced?

49. The equation for the electrolysis of brine is

$$2NaCl(aq) + 2H_2O(l) \longrightarrow Cl_2(g) + H_2(g) + 2NaOH(aq)$$

How would you modify the electrolysis diagram to make it quantitatively represent the formation of hydrogen and chlorine?

***50.** What chemical changes occur during the electrolysis of brine?

LESSON 21.3

46. Voltaic cells convert chemical energy into electrical energy. Electrolytic cells use electrical energy to cause a chemical reaction.

47. $2H_2O(l) \rightarrow O_2(g) + 2H_2(g)$

48. electrode A

49. The small spheres representing molecules of H_2 and Cl_2 would be in 1:1 ratio.

50. Chloride ions are oxidized to produce chlorine gas, and water is reduced to produce hydrogen gas.

51. What are the products of the electrolysis of molten sodium chloride?

52. What are some applications of electrolysis in the field of metallurgy?

53. Describe briefly how you would electroplate a teaspoon with silver.

Understand Concepts

54. Describe the composition of the anode, cathode, and electrolyte in the following:
    a. a fully charged lead storage battery
    b. a fully discharged lead storage battery

*55. Predict what will happen, if anything, when an iron nail is dipped into a solution of copper(II) sulfate. Write the oxidation and reduction half-reactions for this process and the balanced equation for the overall reaction.

56. The standard reduction potential for a cadmium half-cell is −0.40 V. What does this mean?

*57. Calculate E°_{cell} and write the overall cell reaction for these cells.
    a. $Sn \mid Sn^{2+} \parallel Pb^{2+} \mid Pb$
    b. $H_2 \mid H^+ \parallel Br_2 \mid Br^-$

58. Why is it not possible to measure the potential of an isolated half-cell?

59. Complete the data table below for the electrolysis of water.

H_2O used	H_2 formed	O_2 formed
a. 2.0 mol	____ mol	____ mol
b. ____ g	____ g	16.0 g
c. ____ mL	10.0 g	____ g
d. 44.4 g	____ g	____ g
e. ____ g	8.80 L (STP)	____ L (STP)
f. 66.0 mL	____ g	____ L (STP)

*60. What is the relationship between the voltage produced by a redox reaction and the spontaneity of the reaction?

61. The reactions that take place in voltaic cells produce electric current, and the reactions in electrolytic cells can be made to take place when an electric current is applied. What common feature do these redox reactions share?

*62. In one process used to produce aluminum metal, ore containing aluminum oxide is converted to aluminum chloride. Aluminum metal and chlorine gas are then produced by the electrolysis of molten aluminum chloride ($AlCl_3$).
    a. Write the half-reactions that take place at the cathode and the anode.
    b. Write the equation for the overall cell reaction.
    c. Identify the products produced at the cathode and the anode.

63. Use the information in Table 21.2 to determine which of the following cell reactions will proceed spontaneously.
    a. $Zn + Pb^{2+} \longrightarrow ?$
    b. $Cu + Fe^{2+} \longrightarrow ?$
    c. $Ag + Cu^{2+} \longrightarrow ?$
    d. $H_2 + Cu \longrightarrow ?$
    e. $Fe + Pb^{2+} \longrightarrow ?$
    f. $Na + Cl_2 \longrightarrow ?$

64. For each spontaneous reaction in Problem 63, write the half-reaction that takes place at the anode. Write the half-reaction that takes place at the cathode.

65. Write the overall balanced equation for each spontaneous reaction in Problem 63.

66. Determine the standard cell potential for each spontaneous reaction in Problem 63.

67. In certain cases, more than one reaction is possible at an electrode. How can you determine which reaction actually takes place?

*68. Answer the following questions for the electrolysis of brine (concentrated sodium chloride solution).
    a. Write the equations for the two possible reactions that can take place at the anode.
    b. Write the equations for the two possible reactions that can take place at the cathode.
    c. Which reaction actually takes place at the anode? Explain why this reaction takes place in preference to the other possible reaction.
    d. Which reaction actually takes place at the cathode? Explain why this reaction takes place in preference to the other possible reaction.

*69. Identify the stronger oxidizing agent in each of the following pairs:
    a. Li^+, Ca^{2+}
    b. Fe^{3+}, Hg_2^{2+}
    c. Cu^{2+}, Cu^+
    d. Hg^{2+}, I_2

Evaluate

Answers

51. sodium metal and chlorine gas
52. Sample answers: silver-plated jewelry, electrorefining impure lead or copper.
53. Set up an electrolytic cell with a silver rod as the anode, the object to be silver-plated as the cathode, and silver cyanide solution as the electrolyte.
54. a. The anode grid is packed with spongy lead, and the cathode grid is packed with $PbSO_2$. The electrolyte is concentrated sulfuric acid.
    b. The anode and cathode grids are both packed with $PbSO_4$. The electrolyte is very dilute sulfuric acid.
55. Some of the iron dissolves and the nail becomes coated with copper.
    Oxidation: $Fe \rightarrow Fe^{2+} + 2e^-$
    Reduction: $Cu^{2+} + 2e^- \rightarrow Cu$
    $Fe(s) + CuSO_4(aq) \rightarrow FeSO_4(aq) + Cu(s)$
56. The cadmium half-cell has a tendency to undergo oxidation.
57. a. $Sn(s) + Pb^{2+}(aq) \rightarrow Sn^{2+}(aq) + Pb(s)$
    $E^\circ_{cell} = +0.01$ V
    b. $H_2(g) + Br_2(l) \rightarrow 2H^+(aq) + 2Br^-(aq)$
    $E^\circ_{cell} = +1.07$ V
58. Two half-cells are needed because oxidation or reduction cannot occur in isolation. One half-cell gains electrons and one loses them, producing an electric current.
59. a. 2.0, 1.0
    b. 18.0, 2.0
    c. 90, 80
    d. 4.9, 39.5
    e. 7.07, 4.40
    f. 7.3, 41.1
60. If the cell potential for a redox reaction is positive, the reaction is spontaneous as written.
61. In each type of cell, oxidation occurs at the anode and reduction occurs at the cathode.
62. a. Oxidation: $6Cl^-(l) \rightarrow 3Cl_2(g) + 6e^-$ (anode)
    Reduction: $2Al^{3+}(l) + 6e^- \rightarrow 2Al(l)$ (cathode)
    b. $2AlCl_3(l) \rightarrow 2Al(l) + 3Cl_2(g)$
    c. Chlorine gas is produced at anode; liquid aluminum is produced at cathode.
63. a, e, and f are spontaneous; b, c, and d are nonspontaneous.
64. a. $Zn \rightarrow Zn^{2+} + 2e^-$ (anode)
    $Pb^{2+} + 2e^- \rightarrow Pb$ (cathode)
    e. $Fe \rightarrow Fe^{2+} + 2e^-$ (anode)
    $Pb^{2+} + 2e^- \rightarrow Pb$ (cathode)
    f. $Na \rightarrow Na^+ + e^-$ (anode)
    $Cl_2 + 2e^- \rightarrow 2Cl^-$ (cathode)
65. a. $Zn + Pb^{2+} \rightarrow Zn^{2+} + Pb$
    e. $Fe + Pb^{2+} \rightarrow Fe^{2+} + Pb$
    f. $2Na + Cl_2 \rightarrow 2Na^+ + 2Cl^-$
66. a. +0.63 V e. +0.21 V f. +4.07 V
67. It will be the reaction that has the larger cell potential, or more readily oxidized or reduced.
68. a. possible oxidation reactions at anode:
    (i) $2Cl^-(aq) \rightarrow Cl_2(g) + 2e^-$
    (ii) $2H_2O(l) \rightarrow O_2(g) + 4H^-(aq) + 4e^-$
    b. possible reduction reactions at cathode:
    (i) $Na^+(aq) \rightarrow e^- + Na(s)$
    (ii) $2H_2O(l) + 2e \rightarrow H_2(g) + 2OH^-(aq)$
    c. (i) Chloride ions are more readily oxidized to chlorine gas than water molecules are oxidized to oxygen.
    d. (ii) Water molecules are more easily reduced than sodium ions.
69. a. Li^+ b. Fe^{3+} c. Cu^{2+} d. I_2

ASSESSMENT

Answers

70. Gold belongs near the bottom, below silver, because it is one of the least active metals.

71. A direct current flows in one direction only.

72. **a.** $Cr(s) + 3Ag^+(aq) \rightarrow Cr^{3+}(aq) + 3Ag(s)$
$E^\circ_{cell} = +1.54\ V$
b. $2Al(s) + 3Cd^{2+}(aq) \rightarrow 2Al^{3+}(aq) + 3Cd(s)$
$E^\circ_{cell} = +1.26\ V$

THINK CRITICALLY

73. The paste in a dry cell allows for the movement of electrons but not ions.

74. The chemists' definition focuses on the electrons that are produced by oxidation at the anode of a voltaic cell; the dictionary definition is probably based on an electrolytic cell, whose electrodes are defined by the battery terminals to which they are attached.

75. The spoon is being plated with silver.

76. As electrons flow from the anode to the cathode in the external circuit, anions must flow from the cathode compartment to the anode compartment to maintain neutrality in the electrolytes. Anions cannot flow through wire made of copper or any other metal. The cell will not function if the salt bridge is replaced with a metal wire.

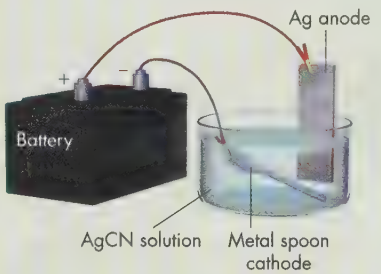
77. $PbSO_4$ and PbO_2 are both solids.

78. **a.** negative electrode (cathode)
b. positive electrode (anode)
c. negative electrode (cathode)
d. negative electrode (cathode)

79. d; the voltage falls steadily.

70. Gold is not included in Table 21.2. Where in the table does gold belong?

***71.** Why is direct current, not alternating current, used in the electroplating of metals?

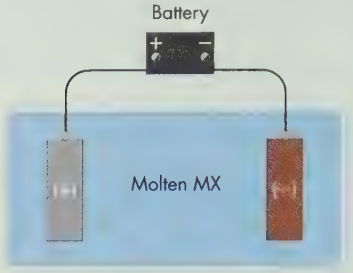


72. Write the overall cell reactions and calculate E°_{cell} for voltaic cells composed of the following sets of half-reactions.
a. $Ag^+(aq) + e^- \longrightarrow Ag(s)$
$Cr^{3+}(aq) + 3e^- \longrightarrow Cr(s)$
b. $Al^{3+}(aq) + 3e^- \longrightarrow Al(s)$
$Cd^{2+}(aq) + 2e^- \longrightarrow Cd(s)$

Think Critically

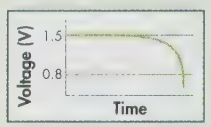
***73.** **Relate Cause and Effect** Lead storage batteries can be recharged. Why are dry cells not rechargeable?

74. **Infer** For any voltaic cell, chemists consider the electrode that produces electrons to be negative, and they call it the anode. Most dictionaries, however, define the anode as the positively charged electrode. Explain.

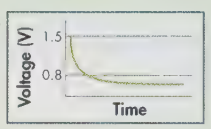


***75.** **Interpret Diagrams** Describe the process that is occurring in the illustration below.

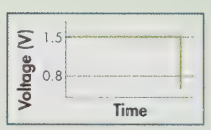
76. **Relate Cause and Effect** In most voltaic cells, the half-cells are connected by a salt bridge or a porous barrier instead of a piece of wire made of copper or some other metal. Why is a metal wire not suitable for connecting the half-cells of a voltaic cell? Explain your answer.

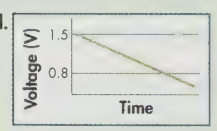


77. **Infer** What property do lead(II) sulfate and lead(IV) oxide have that makes salt bridges unnecessary in a lead storage battery?



78. **Interpret Diagrams** An electrolytic cell is shown below. The substance MX is an ionic compound.





a. At which electrode does reduction occur?
b. At which electrode are electrons being released by ions?
c. At which electrode are electrons entering the cell?
d. At which electrode does elemental M form?

***79.** **Interpret Graphs** Which plot is characteristic of a dry cell? Explain your answer.

a.

b.

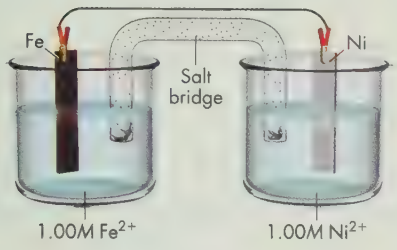
c.

d.

Enrichment

*80. **Calculate** Write the overall cell reactions and calculate E°_{cell} for voltaic cells composed of the following sets of half-reactions.

a. $AgCl(s) + e^- \longrightarrow Ag(s) + Cl^-(aq)$
$Ni^{2+}(aq) + 2e^- \longrightarrow Ni(s)$



b. $Al^{3+}(aq) + 3e^- \longrightarrow Al(s)$
$Cl_2(g) + 2e^- \longrightarrow 2Cl^-(aq)$

81. **Evaluate** An engineer has proposed a new battery design that uses silver as the electrode in both half-cells. As a chemist, what would you tell the engineer about the proposal?

82. **Apply Concepts** Impure copper is purified in an electrolytic cell. Design an electrolytic cell, with H_2SO_4 as the electrolyte, that will allow you to carry out this process. Give the oxidation and reduction half-reactions and a balanced equation for the overall reaction.

83. **Apply Concepts** This spontaneous redox reaction occurs in the voltaic cell illustrated below.

$$Ni^{2+}(aq) + Fe(s) \longrightarrow Ni(s) + Fe^{2+}(aq)$$

a. Identify the anode and the cathode.
b. Assign charges to the electrodes.
c. Write the half-reactions.
d. Calculate the standard cell potential when the half-cells are at standard conditions.

*84. **Relate Cause and Effect** The cells in an automobile battery are separated from each other. However, the electrolyte is the same in all the cells. What would be the consequence of placing all the cells into a single container of electrolyte solution rather than into separate compartments?

Write About Science

85. **Explain** Write a paragraph explaining how a zinc–copper voltaic cell works. Make sure to mention the half-reactions and the overall reaction in your explanation. (*Hint:* Use Figure 21.3 as a reference.)

86. **Compare and Contrast** What do voltaic cells and electrolytic cells have in common? How do they differ?

CHEMYSTERY

Trash or Treasure?

The jeweler informed Maria that she did not purchase a pure gold antique ring but an inexpensive piece of costume jewelry. The ring was in fact made of stainless steel that was electroplated with gold. As Maria wore the ring, the thin layer of gold began to wear off, revealing the stainless steel underneath. However, the jeweler offered to re-plate the inexpensive ring with more gold to restore its original color.

The process by which gold is plated onto another metal is similar to the process by which silver is plated onto an object. The object that is to be gold-plated is the cathode in the electrolytic cell. The anode is metallic gold, which supplies the gold to be deposited onto the object. The electrolyte is a solution of a gold compound. Electroplating of the object occurs when a direct current is applied.

87. **Describe** Draw the electrolytic cell that is used to plate gold onto an object. Label the anode and the cathode and assign charges to the electrodes. Indicate the direction of electron flow and write the half-reactions.

*88. **Infer** How could you remove the gold from a gold-plated object using an electrolytic cell?

89. Connect to the **BIG**IDEA Will the half-reactions in an electrochemical cell used to plate gold onto an object occur if no electric current is supplied to the cell? Explain.

Evaluate

CHEMYSTERY

APPLY CONCEPTS After students have read through the CHEMystery, call on volunteers to summarize how Maria's ring could have been made to look like it was pure gold when it was not. **Ask** Was the redox process used to coat the ring spontaneous or nonspontaneous reaction? *(nonspontaneous)* **Ask** What type of energy was used to drive this reaction? *(electrical energy)* **Ask** During the process of electroplating the ring with gold, does oxidation or reduction occur at the surface of the ring? How do you know? *(Reduction occurs at the surface of the ring because it is the cathode.)*

CHEMYSTERY ANSWERS

87. Students' diagrams should look like 21.11b on page 746. The anode (positive electrode) is gold; the cathode (negative electrode) is the object to be plated. The electrons flow from the anode to the cathode. The half-reactions are as follows:
Anode: $Au(s) \rightarrow Au^+(aq) + e^-$
Cathode: $Au^+(aq) + e^- \rightarrow Au(s)$

88. Connect the positive electrode of the power source to the gold object and the negative electrode to another metal. The gold object serves as the anode and the gold will be oxidized.

89. **BIG**IDEA No, the process is not spontaneous ($E^\circ_{cell} = 0.00$ V).

ASSESSMENT

Answers

ENRICHMENT

80. a. $2AgCl + Ni \rightarrow 2Ag + NiCl_2$
$E^\circ_{cell} = +0.47$ V
b. $3Cl_2 + 2Al \rightarrow 2AlCl_3$
$E^\circ_{cell} = +3.02$ V

81. The battery would not produce a voltage ($E^\circ_{cell} = 0.00$ V).

82. Oxidation:
$2Cu(impure) + 2H_2SO_4 \rightarrow 2Cu^{2+} + 2H_2 + 2SO_4^{2-}$
Reduction:
$2Cu^{2+} + 2SO_4^{2-} + 2H_2O \rightarrow 2Cu(pure) + 2H_2SO_4 + O_2$
Overall reaction:
$2Cu(impure) + 2H_2O \rightarrow 2Cu(pure) + 2H_2 + O_2$

83. a. The iron electrode is the anode; the nickel electrode is the cathode.
b. The anode is negative; the cathode is positive.
c. Oxidation: $Fe(s) \rightarrow Fe^{2+}(aq) + 2e^-$ (anode)
Reduction: $Ni^{2+}(aq) + 2e^- \rightarrow Ni(s)$ (cathode)
d. $E^\circ_{cell} = +0.19$ V

84. The battery output would not be 12 V.

WRITE ABOUT SCIENCE

85. In a zinc–copper voltaic cell, zinc is oxidized and copper ions are reduced.
Anode: $Zn(s) \rightarrow Zn^{2+}(aq) + 2e^-$
Cathode: $Cu^{2+}(aq) + 2e^- \rightarrow Cu(s)$
A zinc rod serves as the anode; a copper rod serves as the cathode. The half-cells are connected by a salt bridge, through which both positive and negative ions migrate. The overall reaction is as follows:
$Zn(s) + Cu^{2+}(aq) \rightarrow Zn^{2+}(aq) + Cu(s)$

86. In both cells, electrons flow from the anode to the cathode through an external circuit. Reduction occurs at the anode; oxidation occurs at the cathode. In a voltaic cell, the flow of electrons is spontaneous; an outside source of power is needed to drive the reaction in an electrolytic cell. The negative electrode is the anode in a voltaic cell; it is the cathode in an electrolytic cell.

***91.** A sample of oxygen gas has a volume of 425 mL at 30°C. What is the new volume of the gas if the temperature is raised to 60°C while the pressure is kept constant?

92. Write formulas for these hydrates.
a. tin(IV) chloride pentahydrate
b. magnesium sulfate heptahydrate
c. iron(III) phosphate tetrahydrate
d. calcium chloride dihydrate

***93.** Calculate the grams of solute required to make the following solutions:
a. 250 g of 0.90% NaCl (m/m)
b. 500 mL of 2.0*M* KNO_3

94. Concentrated nitric acid is 16*M*. How would you prepare 500 mL of 1.0*M* HNO_3 from the concentrated acid?

95. Convert the following:
a. 4.32×10^5 joules to kilojoules
b. 255 Calories to calories
c. 645 calories to joules

96. Calculate the quantity of heat lost or gained in the following changes:
a. 0.625 mol NaOH(*s*) dissolves in water
b. 1.17 mol water freezes at 0°C
c. 0.30 mol $C_2H_6O(l)$ vaporizes
d. 0.66 mol of steam condenses at 100°C

***97.** The combustion of natural gas, methane (CH_4), is an exothermic reaction.

$$CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(l) \quad \Delta H = -890 \text{ kJ}$$

Calculate the amount of heat liberated when 4.80 g CH_4 reacts with an excess of oxygen.

***98.** Four reactions have the following equilibrium constants. Identify in which of these reactions the reactants are favored over products. Why?
a. $K_{eq} = 0.006$ **c.** $K_{eq} = 8 \times 10^{-4}$
b. $K_{eq} = 5.3$ **d.** $K_{eq} = 2 \times 10^3$

99. Give the equilibrium-constant expression for the decomposition of ammonia to nitrogen and hydrogen.

$$2NH_3(g) \rightleftharpoons N_2(g) + 3H_2(g)$$

***100.** Determine the pH for each solution.
a. $[H^+] = 1.0 \times 10^{-8} M$
b. $[H^+] = 0.000010 M$
c. $[OH^-] = 1.0 \times 10^{-4} M$
d. $[OH^-] = 1.0 \times 10^{-9} M$

101. Three solutions have the following pH values. What are the hydroxide-ion concentrations of these solutions?
a. pH = 7.0 **b.** pH = 4.0 **c.** pH = 9.0

102. Write a balanced equation for the reaction of each of the following metals with water:
a. sodium **b.** calcium

***103.** Determine the oxidation number of sulfur in each of the following:
a. H_2SO_4 **c.** SO_2 **e.** S
b. H_2S **d.** $Na_2S_2O_3$ **f.** SO_3^{2-}

104. Determine the oxidation number of each element in these substances.
a. $CaCr_2O_7$ **c.** $Ca(NO_3)_2$
b. $KMnO_4$ **d.** $Al(OH)_3$

***105.** Identify which of the following are oxidation-reduction reactions. If a reaction is a redox reaction, name the element oxidized and the element reduced.
a. $CaCO_3(s) \longrightarrow CaO(s) + CO_2(g)$
b. $Ca(s) + Cl_2(g) \longrightarrow CaCl_2(s)$
c. $Ca(s) + 2H_2O(l) \longrightarrow Ca(OH)_2(aq) + H_2(g)$

106. Balance each redox equation.
a. $Br_2(g) + NaOH(aq) \longrightarrow NaBrO_3(aq) + NaBr(aq) + H_2O(l)$
b. $Fe_2O_3(s) + H_2(g) \longrightarrow Fe(s) + H_2O(l)$

Standardized Test Prep for Indiana

Select the choice that best answers each question or completes each statement.

Tips for Success

Eliminate Wrong Answers If you don't know which response is correct, start by eliminating those you know are wrong. If you can rule out some choices, you'll have fewer left to consider and you'll increase your chances of choosing the correct answer.

1. Which statement describes electrolysis?
   (A) Reduction occurs at the anode.
   (B) Energy is produced.
   (C) Oxidation occurs at the cathode.
   (D) Positive ions move to the cathode.
2. A voltaic cell is constructed using the following half-reactions:

   $Cd^{2+}(aq) + 2e^- \longrightarrow Cd(s) \quad E^\circ_{Cd^{2+}} = -0.40\ V$
   $Sn^{2+}(aq) + 2e^- \longrightarrow Sn(s) \quad E^\circ_{Sn^{2+}} = -0.14\ V$

   What is the standard cell potential for this voltaic cell?
   (A) −0.54 V (C) +0.26 V
   (B) −0.26 V (D) +0.54 V
3. Which of the following is a product of the reaction that occurs in a hydrogen–oxygen fuel cell?
   (A) $CO(g)$ (C) $H_2O(g)$
   (B) $CO_2(g)$ (D) $H_2O_2(l)$
4. Magnesium metal is prepared by the electrolysis of molten $MgCl_2$. One half-reaction is

   $$Mg^{2+}(l) + 2e^- \longrightarrow Mg(l)$$

   Which of the following statements is true?
   (A) This half-reaction occurs at the cathode.
   (B) Magnesium ions are oxidized.
   (C) Chloride ions are reduced at the anode.
   (D) Chloride ions gain electrons during this process.
5. If the cell potential for a redox reaction is positive,
   (A) the redox reaction is spontaneous.
   (B) the redox reaction is not spontaneous.
   (C) the reaction only occurs during electrolysis.
   (D) More than one statement is correct.

Use the data table to answer Questions 6–12. Hydrogen is included as a reference point for the metals.

Activity Series of Selected Metals	
Element	**Oxidation half-reaction**
Lithium	$Li(s) \longrightarrow Li^+(aq) + e^-$
Potassium	$K(s) \longrightarrow K^+(aq) + e^-$
Sodium	$Na(s) \longrightarrow Na^+(aq) + e^-$
Aluminum	$Al(s) \longrightarrow Al^{3+}(aq) + 3e^-$
Zinc	$Zn(s) \longrightarrow Zn^{2+}(aq) + 2e^-$
Iron	$Fe(s) \longrightarrow Fe^{2+}(aq) + 2e^-$
Hydrogen	$H_2(g) \longrightarrow 2H^+(aq) + 2e^-$
Copper	$Cu(s) \longrightarrow Cu^{2+}(aq) + 2e^-$

6. Which metal will more easily lose an electron, sodium or potassium?
7. Which metal is more easily oxidized, copper or aluminum?
8. What is the relationship between ease of oxidation and the activity of a metal?
9. Describe what would happen if you placed a clean strip of aluminum in a solution of copper(II) sulfate. Explain your answer.
10. Would a copper strip placed in a solution containing zinc ions react spontaneously with the zinc ions? Explain your reasoning.
11. Based on the positions of zinc and iron in the table, explain how attaching zinc blocks to a steel ship hull protects the steel from corrosion.
12. Write the half-reaction for the reduction of aluminum ions.
13. An electrolytic cell is shown at the right. Draw this cell on a separate piece of paper and label the anode, cathode, and direction of electron flow.

CHAPTER 22

What's Online

CHEM TUTOR Students access guided, step-by-step tutorials for naming hydrocarbons and identifying asymmetric carbon atoms.

ONLINE PROBLEMS Students can practice key problem-solving skills in an online problem set.

MATH HELP Identify the students that struggle with math by assigning an online math skills diagnostic test. These students can then improve and practice math skills by using the MathXL tutorial system.

VIRTUAL LAB Students go on an animated virtual lab tour in which unsaturated hydrocarbons are studied in a simulated laboratory environment.

KINETIC ART Students watch animations of selected figures from the chapter, and then answer questions that check for understanding.

CONCEPTS IN ACTION Students watch an overview of a key chapter concept using real-world contexts and concrete examples and analogies. Each activity includes an interactive animation followed by analysis questions.

Turkmenistan has some of the world's largest deposits of natural gas. This natural gas deposit in the city of Darvaza has been burning for over three decades!

IN ACADEMIC STANDARDS for SCIENCE

Nature of Science

- Develop explanations based on reproducible data and observations gathered during laboratory investigations.
- Use analogies and models (mathematical and physical) to simplify and represent systems that are difficult to understand or directly experience due to their size, time scale, or complexity, and recognize the limitations of analogies and models.

Standard 9: Organic Chemistry and Biochemistry

C.9.2 Identify the variety of large molecules formed by the covalent bonding of carbon atoms and describe the functions of these molecules.

Also covered C.2.2, C.3.4, C.9.1

Focus on ELL

1 CONTENT AND LANGUAGE Begin the lesson by drawing students' attention to the word *hydrocarbon* or *hydrocarbons* in the chapter title and lesson titles. Explain that the prefix *hydro-* means "containing hydrogen or water." Have students use this information to predict the meaning of the word *hydrocarbon*.

BEGINNING

LOW Write any unfamiliar words from the lesson titles on cards, and have students practice saying each word.

HIGH Use a bilingual dictionary or glossary to find any cognates to any unfamiliar words from the titles.

INTERMEDIATE: LOW/HIGH Use an English dictionary or the glossary to define any unfamiliar words from the titles.

ADVANCED: LOW/HIGH Using the titles only, explain to the group the purpose or main idea of the chapter.

BIGIDEA

CARBON CHEMISTRY

Essential Questions:

1. *How are hydrocarbons named?*
2. *What are the general properties of hydrocarbons?*

CHEMYSTERY

Nose for Hire

Walking home from school one day, Anthony spotted a poster soliciting participants for a smell test. The poster offered participants "$50 for less than an hour of your time." So he decided to go for it.

When Anthony reported for the study, after filling out some paperwork, a researcher asked him to smell two chemical samples. The first one smelled like a freshly cut orange. The second had an odor that reminded him of pine trees.

Anthony was curious. "What am I smelling?" he asked. "Limonene," the researcher answered. "What about the second one?" Anthony asked. The researcher gave the same reply: "Limonene." Anthony was perplexed. How could two substances, both with the name limonene, smell so different?

▶ Connect to the BIGIDEA As you read about hydrocarbons, think about what could make this phenomenon possible.

INDIANA'S ACADEMIC STANDARDS FOR SCIENCE

Atomic Structure and the Periodic Table C.2.2; **Bonding and Molecular Structure** C.3.4; **Organic Chemistry and Biochemistry** C.9.1, C.9.2. See lessons for details.

Introduce the Chapter

IDENTIFYING MISCONCEPTIONS Students may assume that molecules can have only one arrangement. Use these activities to help them realize that compounds can have the same molecular formula but different structures and properties.

Activity 1 *You will need toothpicks and two colors of modeling clay.* Have students make 4 model carbon atoms and 10 model hydrogen atoms. Draw the structure of butane, and have students model it. **Ask** What is its formula? *(C_4H_{10})* Repeat for 2-methylpropane. Explain that the formulas are the same, but the structures and properties differ.

Activity 2 *You will need toothpicks and five colors of modeling clay.* Have students make one model atom each of carbon, hydrogen, fluorine, chlorine, and bromine. Then have them connect the atoms of fluorine and hydrogen to either side of the carbon atom. **Ask** Where should you connect the chlorine and bromine atoms? *(There are two possibilities, depending on the side where each is placed.)* Explain that the two ways represent two compounds with the same molecular formula but different structures and properties.

UbD

Understanding by Design

Students are building toward understanding carbon chemistry by studying the structure and characteristics of hydrocarbon compounds.

PERFORMANCE GOALS At the end of Chapter 22, students will be able to answer the essential questions by applying their knowledge of hydrocarbon compounds. Students will also be able to identify hydrocarbons, based on their structures.

ESSENTIAL QUESTIONS Read the essential questions aloud. **Ask** Based on the name, you can tell that hydrocarbons contain what two elements? *(hydrogen and carbon)* **Ask** What are factors that often determine the names of compounds? *(structure and properties)* **Ask** If hydrocarbons contain just hydrogen and carbon atoms, how is it possible for there to be different types of hydrocarbons? *(The number and arrangement of the two types of atoms must be different.)* **Ask** How is it possible for different hydrocarbons to have different properties if they are all made of just hydrogen and carbon? *(Changing the number and arrangement of the atoms must change the properties of the compounds.)*

BIGIDEA Use the photo of the burning natural gas deposit to help students connect to the concepts they will learn in this chapter. Activate prior knowledge by reminding students that natural gas, along with coal and petroleum, is a fossil fuel. **Ask** What is a fossil fuel? *(the organic remains of ancient organisms)* Explain that over time the organic material broke down to form compounds of carbon and hydrogen atoms, or hydrocarbons. The main component of natural gas is the hydrocarbon methane, CH_4. **Ask** What property does the photo show methane has? *(It is combustible.)* **Ask** What is the equation for the combustion of methane? *($CH_4(g) + 2O_2(g) \rightarrow CO_2(g) + 2H_2O(g) + heat$)*

CHEMYSTERY Have students read over the CHEMystery. Connect the CHEMystery to the Big Idea of Carbon Chemistry by pointing out that the name of the compound Anthony smelled was the same each time. **Ask** If the name is the same, then what must be true about the molecular formulas? *(They must be the same.)* As a hint, have students consider what must be different about compounds that have the same formula but different properties, such as the different smells of limonene. Students should conclude that the two limonene compounds might have different molecular structures.

LESSON 22.1

Key Objectives

EXPLAIN why a carbon atom forms four covalent bonds.

IDENTIFY two possible arrangements of carbon atoms in an alkane.

Additional Resources

Reading and Study Workbook, Lesson 22.1

PearsonChem.com

Engage

CHEMISTRY & YOU Have students read the introduction. **Ask** What do many fuels have in common? *(They are mixtures of compounds called hydrocarbons.)* **Ask** Based on its name, predict the composition of a hydrocarbon. *(Hydrocarbons are compounds that contain only hydrogen and carbon.)*

Activate Prior Knowledge

Briefly review bonding concepts with students. **Ask** What is the difference between an ionic bond and a covalent bond? *(Electrons are transferred between atoms in ionic bonds and shared in covalent bonds.)* **Ask** What type of bonding occurs in carbon? *(covalent bonding)* **Ask** What are valence electrons? *(electrons in the highest occupied energy level of an atom)*

Foundations for Reading

BUILD VOCABULARY Have students use simpler words or phrases to rewrite the definition of *homologous series*.

IN ACADEMIC STANDARDS for SCIENCE

C.3.4 Draw structural formulas for and name simple molecules.

C.9.1 Use structural formulas to illustrate carbon atoms' ability to bond covalently to form many different substances.

C.9.2 Identify the variety of molecular types formed by the covalent bonding of carbon atoms and describe the typical properties of these molecular types.

Also covered C.2.2

22.1 Hydrocarbons

C.2.2 Subatomic particles and atomic structure; **C.3.4** Structural formulas and names; **C.9.1** Use structural formulas: carbon atoms; **C.9.2** Identify the variety of carbon molecules.

CHEMISTRY & YOU

Q: *Why are some fossil fuels gases, some liquids, and some solids?* The gasoline used to fuel this motorcycle is a liquid at STP. So are the diesel fuel used in trucks and buses, and the kerosene used in lanterns. Other fuels are gases or solids. For example, the fuel used in a furnace might be natural gas or a solid such as coal. All these fuels contain mixtures of compounds called hydrocarbons. In this lesson, you will learn about the structure and properties of hydrocarbons.

Key Questions

Why does a carbon atom form four covalent bonds?

What are two possible arrangements of carbon atoms in an alkane?

Vocabulary

- hydrocarbon
- alkane
- straight-chain alkane
- homologous series
- condensed structural formula
- substituent
- alkyl group
- branched-chain alkane

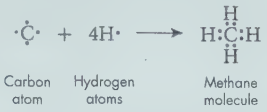
Organic Chemistry and Hydrocarbons

Why does a carbon atom form four covalent bonds?

Fewer than 200 years ago, it was thought that only living organisms could synthesize the carbon compounds found in their cells. So these compounds were classified as organic compounds, and the study of these compounds was known as organic chemistry. Many people thought that a mysterious vital force directed the formation of carbon compounds. A German chemist, Friedrich Wöhler (1800–1882), refuted this idea in 1828. He was able to use inorganic substances to synthesize urea—an organic compound found in urine. Today, organic chemistry includes the chemistry of almost all carbon compounds, regardless of their origin.

Introduction to Hydrocarbons In a reference book that lists properties of common compounds, the list of organic compounds is much longer than the list of inorganic compounds. In fact, new organic compounds are synthesized every day. The simplest organic compounds are called hydrocarbons. By definition, a compound contains at least two elements. A **hydrocarbon** is an organic compound that contains only carbon and hydrogen. The two simplest hydrocarbons are methane and ethane.

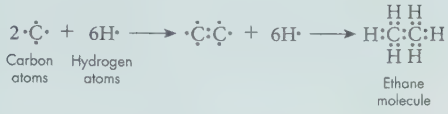
Methane (CH_4) is the major component of natural gas. It is sometimes called marsh gas because it is formed by the action of bacteria on decaying plants in swamps and other marshy areas. Livestock and termites also emit substantial quantities of methane as a product of digestion.



Focus on ELL

1 CONTENT AND LANGUAGE Write the words *primary*, *secondary*, *tertiary*, and *quaternary* on the board and pronounce them for the students. Explain that these words have both common and scientific meanings. Provide the common definitions, and have students write those definitions in their vocabulary notebooks, leaving room to add the scientific definitions as they are encountered in the lesson.

2 FRONTLOAD THE LESSON Review bonding concepts by asking students to explain the difference between ionic and covalent bonds. **Ask** What type of bonding occurs in carbon? *(covalent)* Remind students that only valence electrons participate in bonding.



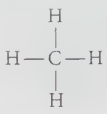
3 COMPREHENSIBLE INPUT As students create their physical models throughout the lesson, guide them to think aloud. Students should verbalize their thought process by asking themselves questions such as, *How many bonds do I need to show? What type of shape does this molecule represent? If I attach this hydrogen atom here, then where should I place the next hydrogen atom?*, and so on.

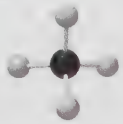
Recall that a carbon atom has four valence electrons and a hydrogen atom has one valence electron. So one carbon atom can form a single covalent bond with four hydrogen atoms as shown below.

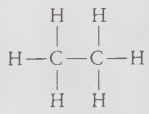
Because carbon has four valence electrons, a carbon atom always forms four covalent bonds. Remembering this principle will help you to write correct structures for organic compounds.

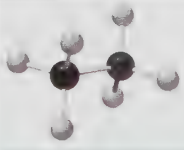
Methane is not typical of the vast majority of organic compounds because there isn't a bond between carbon atoms in a methane molecule. But there is a carbon-carbon bond in ethane. In an ethane molecule, two carbon atoms share a pair of electrons. The remaining six valence electrons form bonding pairs with the electrons from six hydrogen atoms.

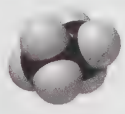
The ability of carbon to form stable carbon-carbon bonds is one reason that carbon can form so many different compounds.











Representing Hydrocarbons Table 22.1 shows the structural formulas, ball-and-stick models, and space-filling models for methane and ethane. Structural formulas are a convenient way to show the arrangement of atoms in a molecule. But two-dimensional structural formulas do not provide accurate information about how the atoms in a molecule are arranged in space. Three-dimensional molecular models represent the shapes of molecules more accurately. Throughout this chapter and the next, ball-and-stick models and space-filling models will be used along with structural formulas to represent organic molecules. Hybrid orbital theory and VSEPR theory are used to predict the molecular shapes.

READING SUPPORT

Build Study Skills: *Cluster Diagram* As you read through the chapter, construct a cluster diagram organizing the different types of hydrocarbons. Use color-coding to distinguish among the groups. ***How will this diagram help you learn about hydrocarbons?***

Table 22.1

Different Ways of Representing Hydrocarbons

Name	Structural formula	Ball-and-stick model	Space-filling model
Methane			
Ethane			

UbD Check for Understanding

Why does a carbon atom form four covalent bonds?

Provide each student with enough modeling supplies to create a model that can be used to explain why a carbon atom is able to form four covalent bonds. Ask students to answer the key question with a one-minute response, using the model as a visual aid.

ADJUST INSTRUCTION If students are struggling with this concept, refer them to Lesson 8.3 and ask them to revisit VSEPR theory. Encourage students to revise their models.

READING STRATEGY Preview the visuals, having students pay particular attention to the terms associated with the chemical structures. Have students make flashcards to assist them in recalling important parts of hydrocarbon structures, such as methylene groups and the four types of carbons.

Explain

Organic Chemistry and Hydrocarbons

USE VISUALS Draw students' attention to the electron dot structures representing methane and ethane in the equations at the top of the page. Then, have students study the structural formulas and ball-and-stick models in Table 22.1. Explain that in these types of structures, lines and sticks are used to represent the electron pairs represented by dots in the dot structures. **Ask** How many lines or sticks are needed to represent one pair of electrons in a covalent bond? *(one line or stick)* Tell students to keep this in mind as they proceed through the lesson.

Explore

Teacher Demo

PURPOSE Students observe the three-dimensional shape of the simplest hydrocarbon, methane.

MATERIALS colored foam balls, applicator sticks

PROCEDURE Use colored foam balls and applicator sticks to construct models that are large enough for all the students to see. Review the tetravalency of carbon as well as the octet rule. To assess students' knowledge about molecular shape, **Ask** Why does methane have a tetrahedral shape? *(VSEPR theory states that because electron pairs repel each other, electron pairs are as far apart as possible in molecules.)* Explain that one of the key ideas of organic chemistry is structure dictates function; the arrangement of atoms is as important as the number and type of atoms.

Extend

Connect to GEOLOGY

Explain that because the carbon bond is incredibly strong and can occur with so many nonmetals, millions of carbon compounds exist. Through the study of biochemistry, scientists have learned that these carbon-based, organic compounds are fundamental to life. In a similar manner, silicon, also a Group 4 element, is fundamental to most inorganic substances on Earth. Have students create a visual representation that demonstrates the analogous relationship between carbon–organic–life and silicon–inorganic–Earth.

Explore

Class Activity

PURPOSE Students construct a ball-and-stick model of ethane.

MATERIALS colored foam balls, applicator sticks

PROCEDURE Have students construct a ball-and-stick model of ethane. Check the models for tetrahedral geometry at each carbon. **Ask** How many covalent bonds are there in ethane? *(7)* **Ask** Why are three-dimensional models a more accurate representation of organic molecules than are two-dimensional models? *(Three-dimensional models convey the spatial relationships among the atoms.)*

Extend

Connect to PHYSIOLOGY Prepare a large test tube with equal volumes of water and either mineral oil or baby oil. A small amount of food coloring can be added to the water to more clearly demarcate the polar and nonpolar phases. Shake the test tube vigorously and allow the phases to separate. Tell students to pay attention to the behavior of the oil as it separates from the water. Remind students that an enzyme molecule can catalyze the breakdown of an organic molecule only if it can attach to the molecule. Point out that in the small intestine, the digestive matter, called *chyme*, contains both fats and aqueous materials. **Ask** How does the digestive system reduce the tendency of fats and water to separate? *(The liver secretes bile to emulsify the fat.)* Have students create a poster illustrating how bile works to emulsify fat and how an inability of the liver to produce bile affects nutrient absorption.

Explain

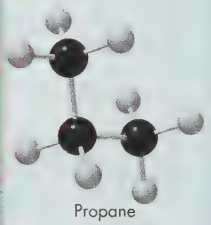
Alkanes

USE VISUALS Direct students' attention to the ball-and-stick structures in Figure 22.2. Have students compare these structures to the one they created for ethane. Point out that, although all three structures are called straight-chain alkanes, in reality chains of three or more carbons are not arranged in a perfectly straight line because the bond angles of a carbon atom are not equal to 180°.

Figure 22.1 Oil and Water
The nonpolar molecules in this cooking oil are not attracted to the polar water molecules, so they do not mix.
Interpret Photos ***What evidence of insolubility do you see in the photo?***

Properties of Hydrocarbons The electron pair in a carbon-hydrogen bond or a carbon-carbon bond is shared almost equally by the nuclei of the atoms forming the bond. Thus, hydrocarbons are nonpolar molecules. The attractions between nonpolar molecules are weak van der Waals forces. So hydrocarbons with low molar masses tend to be gases or liquids that boil at a low temperature.

Recall the general rule "like dissolves like." Two nonpolar compounds will form a solution, as will two polar compounds. But a nonpolar compound and a polar compound will not form a solution. For example, because oil is a mixture of hydrocarbons, oil and water do not mix. So oil will float on top of water, as shown in Figure 22.1.



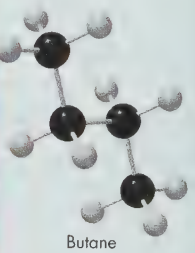
Alkanes

What are two possible arrangements of carbon atoms in an alkane?

Methane and ethane are examples of alkanes. An **alkane** is a hydrocarbon in which there are only single covalent bonds. In any alkane, all the carbon-carbon bonds are single covalent bonds, and all the other bonds are carbon-hydrogen bonds. **The carbon atoms in an alkane can be arranged in a straight chain or in a chain that has branches.**

Straight-Chain Alkanes Ethane is the simplest **straight-chain alkane,** which is an alkane that contains any number of carbon atoms, one after the other, in a chain. Propane (C_3H_8) has three carbon atoms bonded in a chain with eight electrons shared with eight hydrogen atoms. Butane (C_4H_{10}) has a chain of four carbons and ten hydrogens. Figure 22.2 shows how propane and butane can be used.

Propane



Butane

Figure 22.2 Hydrocarbon Fuels
Hydrocarbons are commonly used as fuels. **a.** Pressurized tanks of propane are used to fuel the burners in hot-air balloons. **b.** Butane serves as the fuel for many kitchen torches.

Go online to learn more about hydrocarbon fuels.

Differentiated Instruction

LPR LESS PROFICIENT READERS Have students list the lesson objectives in their notebooks, leaving space after each objective. As they read the section, they should list terms and phrases that provide the information requested for each objective. Check their entries for accuracy.

ELL ENGLISH LANGUAGE LEARNERS Encourage students to locate the vocabulary terms in the lesson. Have students compile an illustrated glossary in which they define each term in English and in their native language.

L3 ADVANCED STUDENTS Have students research sources of methane and methane's relationship to the greenhouse effect and global warming. Questions to be answered could include *What is the greenhouse effect, and how does methane contribute to it?, What are the major sources of methane in the Earth's atmosphere?,* and *Is the methane content of Earth's atmosphere increasing or decreasing?*

InterpretGraphs

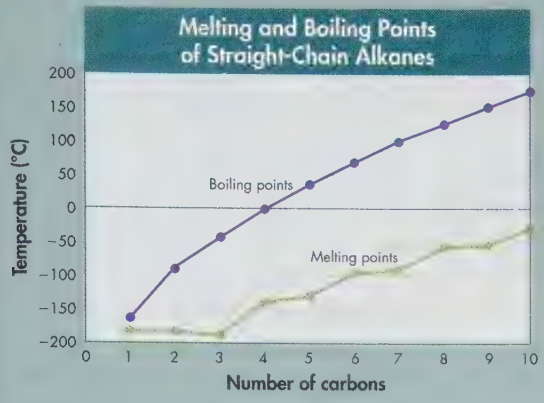


Figure 22.3 The graph illustrates how the melting and boiling points vary with the number of carbons in straight-chain alkanes.

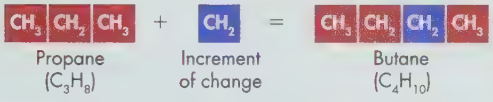


a. Describe Determine whether each alkane is a solid, liquid, or gas at room temperature.

b. Read Graphs How do the added carbons affect the boiling points of the straight-chain alkanes?

c. Predict Estimate a boiling point for undecane, the straight-chain alkane with eleven carbons.

Figure 22.3 shows the melting and boiling points for straight-chain alkanes containing up to ten carbons. The straight-chain alkanes are an example of a homologous series. A group of compounds forms a **homologous series** if there is a constant increment of change in molecular structure from one compound in the series to the next. A CH_2 group is the increment of change in straight-chain alkanes. This change is summarized below for the initial part of the homologous series.

Notice in Figure 22.3 that the boiling points of the straight-chain alkanes increase as the number of carbons in the chain increase. The melting points increase in a similar way.

Naming Straight-Chain Alkanes The names of straight-chain alkanes follow rules established by the International Union of Pure and Applied Chemistry (IUPAC). Every alkane has a name that ends with the suffix *-ane*. For the straight-chain alkanes with one to four carbon atoms, the official names and the common names are the same. They are methane, ethane, propane, and butane, respectively. A mixture of Latin and Greek prefixes are used to name the hydrocarbons having straight chains longer than four carbon atoms. The prefixes are *pent-* for 5, *hex-* for 6, *hept-* for 7, and so on. Use Table 22.2 to memorize the names of the first ten straight-chain alkanes.

Table 22.2
Straight-Chain Alkanes

Name	Formula
Methane	CH_4
Ethane	C_2H_6
Propane	C_3H_8
Butane	C_4H_{10}
Pentane	C_5H_{12}
Hexane	C_6H_{14}
Heptane	C_7H_{16}
Octane	C_8H_{18}
Nonane	C_9H_{20}
Decane	$C_{10}H_{22}$

Professional Development Note

Organic Discoveries

An organic chemist uses scientific theories and scientific methods to design and build a molecule with a specific set of new properties. To confirm the identity of new molecules, organic chemists use infrared (IR) spectroscopy and nuclear magnetic resonance (NMR) spectrometry to analyze the structures. IR spectroscopy determines the frequencies of infrared radiation absorbed by a molecule. The resulting spectrum is a "fingerprint" of the compound. With NMR spectrometry, many atoms can be identified by the characteristic radio frequencies that they absorb when placed in a magnetic field.

Explore

TeacherDemo

PURPOSE Students compare molecular models and structural formulas of alkanes.

MATERIALS foam balls and applicator sticks or molecular model sets

PROCEDURE Write the complete structural formulas for methane, ethane, propane, and butane on the board. Ask students how the structures are similar and how they are different. Then show students a molecular model for each of the compounds. Pull apart an ethane model and show how a —CH_2— (methylene) group can be inserted between the —CH_3 (methyl) groups to make larger alkanes. Use the models of propane and butane to show how the tetrahedral arrangement of the atoms around each carbon results in a "zigzag" shape for the carbon backbone. Illustrate the rotational freedom of the atoms in a saturated hydrocarbon by twisting the models of propane and butane about the carbon-carbon axis. Once students understand how the atoms are joined in the larger alkanes, write the condensed structural formulas under the complete structural formulas for ethane, propane, and butane. Explain that the condensed formulas are a convenient shorthand notation.

DRAW A CONCLUSION If possible, bring samples of methane, hexane, and paraffin wax to class. On the board, create a table containing the condensed formulas and boiling points of methane (CH_4, –161.0°C) and hexane (C_6H_{14}, 68.7°C). Add paraffin wax to the table, below hexane. Explain to students that paraffin wax is a mixture of alkanes and so does not have a specific condensed chemical formula. Point out that it has a melting point of approximately 56°C, at which point it becomes an oil. **Ask** Based on the melting point of the solid, how do you think the boiling point of paraffin oil compares to those of methane and hexane? *(It is higher.)* Tell students that the boiling point of paraffin oil is significantly higher—at least 260°C. **Ask** Based on this information, what inference can you make about the chain lengths of the alkanes in paraffin? *(They are greater in length than hexane.)* **Ask** What can you conclude about the attraction between molecules as the number of carbon atoms increases? *(The intermolecular attractions increase.)*

Answers

FIGURE 22.1 The two phases remain separate.

INTERPRET GRAPHS

a. Methane through butane are gases; pentane through decane are liquids.

b. As carbon number increases, the boiling point increases.

c. A good estimate is around 200°C. The actual value is 196°C.

Explain

CHEMISTRY & YOU Some hydrocarbon fuels, such as natural gas, consist of lighter hydrocarbons that have boiling points below 20°C. These fuels are gases. Other hydrocarbon fuels, such as gasoline or diesel fuel, are comprised of heavier hydrocarbons, which have comparatively higher boiling points and thus are liquids.

USE AN ANALOGY Introduce Table 22.3 by asking students to write down every name and nickname they are called or referred to by their friends, families, teachers, strangers, and so on. Ask volunteers to share their lists and to share how and why the various names came to be. **Ask** Who has the greatest number of names? **Ask** Does the name used to address you change who you are as a person? *(no)* State that these various references to a person are like the various ways in which a chemical formula may be written. Just as the name that is used to address you does not change the essence of you, the formula used to describe butane or any other carbon compound does not change the properties and characteristics of the compound.

APPLY CONCEPTS Suggest that students create flashcards of the names and structures of the first ten straight-chain alkanes and commit them to memory. **Ask** Why are some alkanes called straight-chain alkanes? *(The carbon atoms form an unbroken line. Each carbon atom within the chain is bonded to no more than two other carbon atoms.)* **Ask** What do you think is meant by the term *branched-chain alkane*? *(Sample answer: The carbons branch off from the carbon chain.)*

CHEMISTRY & YOU

Q: *Hydrocarbons such as alkanes can be used as fuels. You just learned that the boiling and melting points of straight-chain alkanes increase as the number of carbons increase. Now explain why some hydrocarbon fuels are gases and others are liquids.*

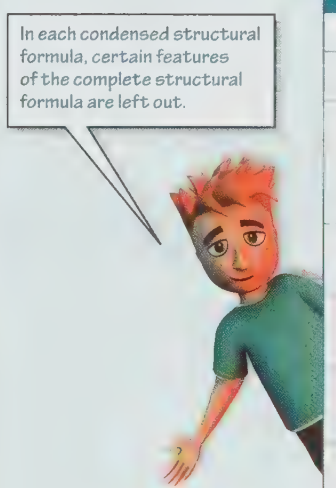
Drawing Structural Formulas for Straight-Chain Alkanes To draw the structural formula for a straight-chain alkane, write the symbol for carbon as many times as necessary to get the proper chain length. Then complete the formula with hydrogens and lines representing covalent bonds. Complete structural formulas show all the atoms and bonds in a molecule. Sometimes, however, shorthand or condensed structural formulas work just as well. In a **condensed structural formula,** some bonds and/or atoms are left out of the structural formula. Although the bonds and atoms do not appear, you must understand that they are there.

A condensed structural formula in the form of $CH_3(CH_2)_nCH_3$ uses a different kind of shorthand. The CH_2 unit in parentheses is called a methylene group. The subscript n to the right of the parentheses indicates the number of methylene groups that are linked together. This shorthand method applies to butane as follows:

$CH_3(CH_2)_2CH_3$

Methylene unit — Subscript

The subscript after the parentheses in the condensed structural formula for butane is 2. This means two methylene groups are linked together in the structure. Table 22.3 shows several ways to draw condensed structural formulas, using butane as an example.



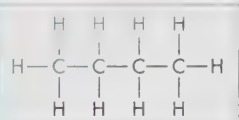


Table 22.3

Formulas for Butane

Formula	Description
C_4H_{10}	Molecular formula
	Complete structural formula
$CH_3—CH_2—CH_2—CH_3$	Condensed structural formula (C—H bonds understood)
$CH_3CH_2CH_2CH_3$	Condensed structural formula (C—H and C—C bonds understood)
$CH_3(CH_2)_2CH_3$	Condensed structural formula (all bonds understood)
C—C—C—C	Carbon skeleton (hydrogens and C—H bonds understood)
	Line-angle formula (carbons and hydrogens understood) Carbon atoms are located at each intersection and at the ends of lines.

Professional Development Note

Carbocations

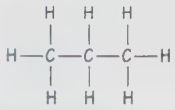
George Olah won the 1994 Nobel Prize in Chemistry for his work with hydrocarbons. Olah showed that some chemical reactions involving hydrocarbons proceed through short-lived, highly reactive intermediate compounds, which he called carbocations. Olah was able to produce, isolate, and preserve carbocations so that they could be studied in detail.

The name *carbocations* means "carbon cations." A carbocation has a positive charge on carbon, thus only three shared pairs of electrons around the element, instead of four. Because the octet is not complete, carbocations are unstable and reactive. When used as an intermediate in an organic reaction, a carbocation is typically considered to be the rate-determining step for the reaction.

Sample Problem 22.1

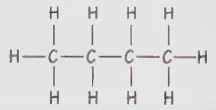
Drawing Structural Formulas for Alkanes

Draw complete structural formulas for the straight-chain alkanes that have
a. three carbon atoms. **b.** four carbon atoms.



1 Analyze **Identify the relevant concepts.** In an alkane, each carbon atom forms four covalent bonds to hydrogen or to other carbon atoms. Because these are straight-chain alkanes, write the appropriate number of carbons in a straight line, connected to each other by single bonds. Then add the appropriate number of hydrogen atoms.

2 Solve **Apply the concepts to this problem.**

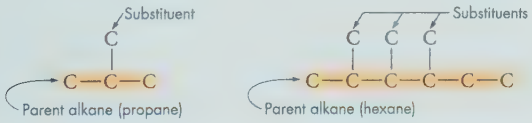


Start with the number of carbons.

Each center carbon bonds to two hydrogens. Each end carbon bonds to three hydrogens.

a. C—C—C

b. C—C—C—C



Make sure that each carbon has 4 bonds.

1. Draw complete structural formulas for the straight-chain alkanes with five and six carbon atoms.

2. How many single bonds are there in a propane molecule?

Branched-Chain Alkanes Alkanes and other hydrocarbons do not always have carbon atoms bonded in straight chains. Because a carbon atom forms four covalent bonds, it can bond not only to one or two other carbon atoms, but also to three or even four other carbons, resulting in branched chains. In organic chemistry, branches on a hydrocarbon chain are discussed as if they were substituted for a hydrogen atom on the chain. An atom or group of atoms that can take the place of a hydrogen atom on a parent hydrocarbon molecule is called a **substituent.** Look at the diagrams below. The longest continuous carbon chain of a branched-chain hydrocarbon is called the parent alkane. All other carbon atoms or groups of carbon atoms are regarded as substituents. In Chapter 23, you will study compounds in which atoms such as halogens, oxygen, and nitrogen can take the place of a hydrogen atom on the carbon chain.

UbD Check for Understanding

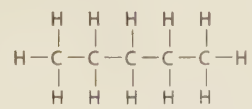
To assess students' understanding of the lesson vocabulary, ask students to create a crossword puzzle utilizing the concepts in the lesson, the vocabulary, the labs, and so on. Students should provide a clue for each item. Encourage students to use the Internet to find a free crossword puzzle creator. Have pairs of students exchange crosswords and complete and evaluate each other's creations.

ADJUST INSTRUCTION If students are having difficulty understanding the vocabulary, review the explanations in the text and help students write definitions using their own words. Verify that students' definitions are accurate.

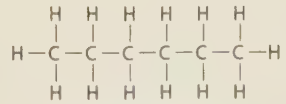
Extend

Connect to PHYSICAL CONSTANTS

Have students organize several of the first C_nH_{2n+2} compounds, where $n \leq 40$, into groups with similar characteristics. For instance, students might group compounds according to their states of matter at STP. Ask students to research paraffin and how it relates to hydrocarbons. *(Long-chain alkanes are called paraffins. In their solid state, they are known as paraffin wax. In their liquid state, they are known as either paraffin oil or mineral oil.)*



Sample Practice Problem



A. How many single bonds are there in a straight-chain pentane molecule? *(16)*

B. How many single bonds are there in a butane molecule? *(13)*

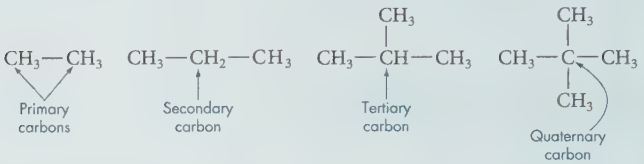
Answers

1.

2. 10 single bonds

Explain

MAKE A CONNECTION Draw the structural formulas for the following alkyl groups in a line down the board: methyl, ethyl, and propyl. To the right of each structure, draw the structures for the following alkanes, using a different color for the last hydrogen: methane, ethane, and propane. Point out to the students that they can use the shared word root to determine the number of carbons in an unfamiliar alkyl group or to identify an alkyl group on the basis of its structure.



APPLY CONCEPTS Direct students to the photograph in Figure 22.4. State that gas stations typically offer three different fuels: regular, mid-grade, and premium. **Ask** What is the basis for your decision in choosing the type of gasoline you (or your family or friends) pump into your car? *(Sample answers: octane rating, cost per gallon, type of car, type of engine, performance, speed, manufacturer's recommendation)* **Ask** Why do you think one type of gasoline costs more than another type? *(Sample answers: higher octane rating, preservatives added, better engine performance)* Explain that prior to pumping gasoline into a car, the owner should check the car manual to determine the fuel specifications needed for that specific car. Explain that the fuel choices at the pump—regular, mid-grade, and premium—relate to the octane rating of the fuel. The octane level required by an engine is determined by its compression ratio—cars with higher-compression engines require higher octane, or premium, fuel.

Misconception Alert

Students may have heard that higher octane fuel will make a car go faster. Explain that this is not true; the octane rating simply rates the fuel's resistance to knocking.

A hydrocarbon substituent that is derived from an alkane is called an **alkyl group.** You can think of an alkyl group as just an alkane with one of the hydrogens removed. An alkyl group can be one carbon or several carbons long. Alkyl groups are named by removing the *-ane* ending from the parent hydrocarbon name and adding *-yl*. The three smallest alkyl groups are the methyl group (— CH_3), the ethyl group (— CH_2CH_3), and the propyl group (— $CH_2CH_2CH_3$).

When a substituent alkyl group is attached to a straight-chain hydrocarbon, branches are formed. An alkane with one or more alkyl groups is called a **branched-chain alkane.** Each carbon in an organic molecule can be categorized as a primary, secondary, tertiary, or quaternary carbon. If the carbon in question has only one carbon attached to it, then the carbon is a primary carbon. If two carbons are attached to the carbon in question, the carbon is a secondary carbon; if three carbons, a tertiary carbon; and if four carbons, a quaternary carbon. Examples of primary, secondary, tertiary, and quaternary carbons are labeled in the structural formulas below.

Isooctane is a hydrocarbon that contains each of these types of carbons. You have probably seen labels for octane ratings in gasoline as shown in Figure 22.4. Isooctane is the standard for determining octane ratings of the mixtures of hydrocarbons that make up gasoline. A gasoline's octane rating is a measure of its ability to prevent engine knock, which is the sound an internal combustion engine makes when gasoline ignites too soon. Knocking reduces a vehicle's performance and can eventually lead to engine damage.

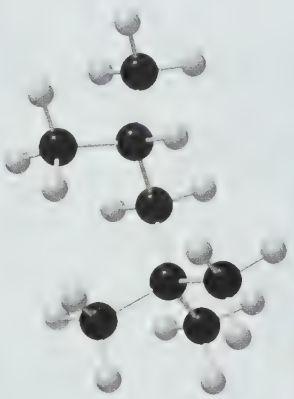


Figure 22.4 Isooctane
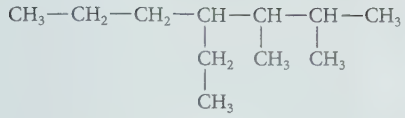
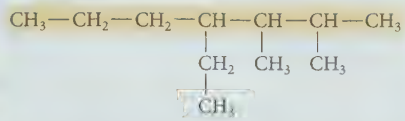
Octane ratings of gasoline are relative to that of isooctane, a good anti-knock fuel, which is assigned a value of 100.
Interpret Diagrams *Find each type of carbon—primary, secondary, tertiary, and quaternary—in the model of isooctane.*



Professional Development Note

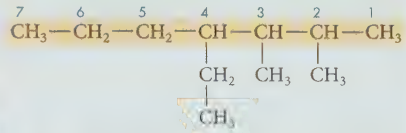
Octane Ratings



The octane system was developed as a way of determining how likely a fuel is to cause engine knocking. The fuels are tested against two standard fuels: isooctane and heptane. Isooctane is very resistant to knocking and has an arbitrary octane rating of 100. Heptane is very prone to knocking and has an arbitrary rating of 0. Every fuel tested is assigned an octane number relative to the controls, based on the fuel's performance in a special test engine. A fuel with octane rating of 89 performs the same as a mixture that is 89 parts isooctane and 11 parts heptane.

Fuels are tested under two sets of driving conditions. The motor (M) octane rating test simulates high-speed driving with heavy loads. The research (R) octane rating test simulates normal driving conditions. The (R + M)/2 octane rating at the gas pump is an average of the two tests' results.

Naming Branched-Chain Alkanes The IUPAC rules for naming branched-chain alkanes are quite straightforward. The name of a branched-chain alkane is based on the name of the longest continuous carbon chain. Each substituent is named according to the length of its chain and numbered according to its position on the main chain. The compound with the structural formula shown to the right can be used as an example.



1. Find the longest continuous chain of carbons in the molecule. This chain is considered the parent hydrocarbon.

The longest chain is highlighted in the example. It contains seven carbon atoms. So, the parent hydrocarbon is heptane.

2. Number the carbons in the main chain in sequence. To do this, start at the end that will give the substituent groups attached to the chain the smallest numbers.

Numbering the chain from right to left gives the substituents the lowest numbers (2, 3, and 4). Numbering the chain the other way violates the rule.

3. Add numbers to the names of the substituent groups to identify their positions on the chain. These numbers become prefixes to the name of the substituent group.

The substituents and positions are 2-methyl, 3-methyl, and 4-ethyl.

4. Use prefixes to indicate the appearance of the same group more than once in the structural formula. Common prefixes are *di-* (twice), *tri-* (three times), and *tetra-* (four times).

The two methyl groups are combined as 2,3-dimethyl.

5. List the names of alkyl substituents in alphabetical order. For purposes of alphabetizing, ignore the prefixes *di-*, *tri-*, and so on.

The 4-ethyl group is listed first, followed by 2,3-dimethyl.

6. Combine all the parts and use proper punctuation. Write the entire name without any spaces. Use commas to separate numbers and use hyphens to separate numbers and words.

The correct name of the compound is 4-ethyl-2,3-dimethylheptane. It is incorrect to write the name as 4-ethyl-2,3-dimethyl heptane.

Differentiated Instruction

L1 LESS PROFICIENT READERS Provide students with a copy of the IUPAC rules for naming branched-chain alkanes. Have students organize the rules into a two-column chart, one column for the rule, the other for a description and an example.

ELL ENGLISH LANGUAGE LEARNERS Prior to introducing the IUPAC rules, write a few names of alkanes on the board and read them aloud for the class. Have students practice stating the numbers and punctuation associated with the names. Provide students with a separate reference sheet that includes common prefixes as well as rules for when and how to use commas and hyphens.

L3 ADVANCED STUDENTS Have students create a set of index cards with large colorful hyphens, numbers, prefixes, names of substituents, and the symbols C, CH, CH_2, CH_3, and CH_4 on separate cards. Then, direct students to use their cards to guide others through the IUPAC rules. Have students use the symbol and hyphen cards to create a representation of a branched-chain alkane. Then have students use the prefix, hyphen, number, and substituent cards to "build" the name of the compound, and vice-versa.

Explain

USE A MODEL Discuss how branched-chain alkanes differ from straight-chain alkanes. Remind students of the activity they performed at the beginning of the chapter, using clay and toothpicks to build butane. Use ball-and-stick models to remind students how straight-chain butane (C_4H_{10}) can be rearranged as a branched-chain structure (2-methylpropane) with the same molecular formula. Stress that each arrangement of atoms represents a different compound with different physical and chemical properties. Repeat the demonstration, this time beginning with a model of pentane, and rearranging it into other branched-chain alkanes. Display the IUPAC naming rules using an overhead or LCD projector. Have students take turns using the rules to name the structures you create.

Explore

Class Activity

PURPOSE Students distinguish between the parent structures and the substituents in a branched-chain hydrocarbon.

MATERIALS different-colored markers

PROCEDURE Write structural formulas for branched-chain hydrocarbons on the board in order from simplest to most complex. Include formulas in which the longest chain is not drawn in a straight line. Have students use one color to circle the carbons in the parent structure, another to circle the methyl groups, and so on.

Answers

FIGURE 22.4 Check students' diagrams.

Explain

Misconception Alert

Students may shy away from the longer, more confusing structures, thinking that the naming procedure is too difficult to follow. Guide students to simply follow one rule at a time. Encourage them to cover up the bulk of the structure and focus directly on the simple alkane that is its root.

Sample Practice Problems

Name the following compounds according to IUPAC system.

A. $CH_3-\underset{\displaystyle CH_3}{\underset{|}{CH}}-CH_2-CH_2-CH_3$ *(2-methylpentane)*

B. $\underset{\displaystyle CH_3}{\underset{|}{CH_2}}-CH_2-CH_2-\underset{\displaystyle CH_2\ CH_3}{\underset{|\quad\ |}{CH}}-\underset{\displaystyle CH_3}{\underset{|}{CH_2}}$ *(3-ethylheptane)*

Sample Problem 22.2

Naming Branched-Chain Alkanes

Name this compound using the IUPAC system. Notice that the longest chain is not written in a straight line.

$$CH_3-CH_2-\underset{\displaystyle CH_2-CH_2-CH_3}{\underset{|}{C}}-CH_3$$

1 Analyze **Identify the relevant concepts.** The parent structure is the longest chain of carbons. All other groups are substituents. Number the carbons to give the first substituent the lowest possible number. These location numbers become part of the name as prefixes. List the names of the substituents in alphabetical order with numbers separated by commas, and numbers and words separated by hyphens.

2 Solve **Apply the concepts to this problem.**

Identify the longest carbon chain in the molecule.

The longest chain has six carbons, so the name ends with hexane.

Identify the substituents and their positions on the parent hydrocarbon.

There are two methyl substituents on carbon 3, so the prefix is 3,3-dimethyl.

substituents

$$\overset{1}{CH_3}-\overset{2}{CH_2}-\overset{3}{\underset{\displaystyle CH_3}{\underset{|}{C}}}-\overset{4}{CH_2}-\overset{5}{CH_2}-\overset{6}{CH_3}$$

Remember to start numbering at the end that gives the substituents the smallest numbers!

Put everything together. You can skip the alphabetizing step because there is only one type of substituent.

The correct IUPAC name is 3,3-dimethylhexane.

3. Name these compound according to the IUPAC system.

a. $CH_2-CH_2-\underset{\displaystyle CH_2}{\underset{|}{CH}}-CH_2-CH_3$ (CH₃ on the first CH₂; CH₃ on the CH₂ branch)

b. $CH_3-CH_2-\underset{\displaystyle CH_3}{\underset{|}{CH}}-CH_3$

4. Name the following compound according to the IUPAC system.

$$CH_3-CH_2-CH_2-\underset{\displaystyle CH_2-CH-CH_3}{\underset{|}{CH}}-CH_2-CH_3$$

Drawing Structural Formulas for Branched-Chain Alkanes With the name of a branched-chain alkane and knowledge of the IUPAC rules, it is easy to reconstruct the structural formula. First, find the root word (ending in *-ane*) in the hydrocarbon name. Then, draw the longest carbon chain to create the parent hydrocarbon, and number the carbons on the chain. Next, identify the substituent groups in the hydrocarbon name. Attach the substituents to the numbered parent chain at the proper positions. Complete the structural formula by adding hydrogens as needed.

Foundations for Math

NUMBER VARIATION Explain that the names of chemical compounds, as well as ions, molecules, and so on, rely on a numbering system that requires an understanding of the English and Roman numbering system as well as Greek and Latin numerical prefixes.

In Sample Problem 22.2, the name of the structure is *3,3-dimethylhexane*. The *3,3-di* indicates that the third carbon in the chain has two substituents attached to it. In **Sample Problem 22.3**, the name of the given compound begins with *2,2,4-tri*. This indicates that there are a total of three substituents, two attached to the second carbon in the chain and one attached to the fourth carbon in the chain.

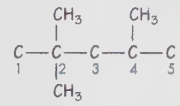
Sample Problem 22.3

Drawing Structural Formulas for Branched-Chain Alkanes

Draw the structural formula for 2,2,4-trimethylpentane, or isooctane.

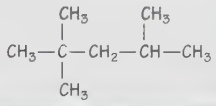
1 Analyze **Identify the relevant concepts.** The part of the name that ends in *-ane* indicates the parent structure. Prefixes indicate the types of substituents, the number of times each appears, and their locations on the parent chain. Hydrogens are added as needed.

2 Solve **Apply the concepts to this problem.**



Draw the number of carbons needed to represent the parent structure indicated in the name, and number the carbons on the chain.

The parent structure is pentane, which has five carbon atoms.



Attach each substituent as indicated in the prefix.

There are two methyl groups on carbon 2 and one on carbon 4.

Finish by adding hydrogens where needed in the formula.

A total of nine hydrogens need to be added to complete the structure.

Be careful: Each carbon has four, and only four, bonds.

5. Draw the structural formula for 2,3-dimethylhexane.

6. Draw the structural formula for 4-ethyl-2,3,4-trimethyloctane.

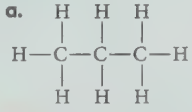
22.1 LessonCheck

7. Review Why do carbon atoms form four covalent bonds?

8. Identify What are two ways that carbon atoms can be arranged in an alkane?

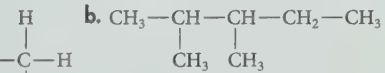
9. Infer Explain why mineral oil, which is a mixture of hydrocarbons, is not soluble in water.

10. Describe Draw complete structural formulas for the following alkanes:



a. octane

b. 3-ethylhexane



11. Describe Write a condensed structural formula for 2,2-dimethylbutane.

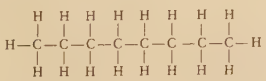
12. Identify Name the following alkanes using the IUPAC system.

a.

b.

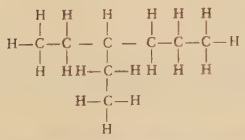
BIG IDEA CARBON CHEMISTRY

13. How would you characterize alkanes in terms of bond polarity?



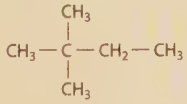
Lesson Check Answers

7. because a carbon atom contains four valence electrons



8. in a straight chain or in a chain with branches

9. The nonpolar hydrocarbons in mineral oil will not form a solution with a polar compound such as water.



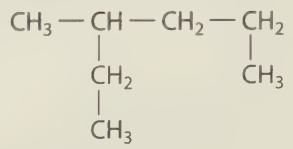
10. a.

b.

11.

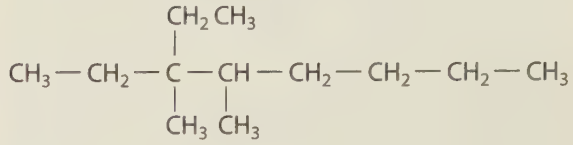
12. a. propane

b. 2,3-dimethylpentane



13. BIG IDEA Alkane are nonpolar.

MAKE A CONNECTION Tell students that the branched-chain alkane in Sample Problem 22.3 is also known as isooctane. This isomer of octane defines the 100 point maximum on the octane rating scale for fuel.



Sample Practice Problems

Draw the structural formulas for these compounds.

A. 3-methylhexane

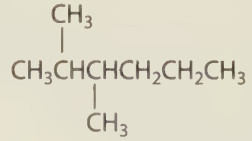
B. 3-ethyl-3,4-dimethyloctane

Evaluate

Informal Assessment

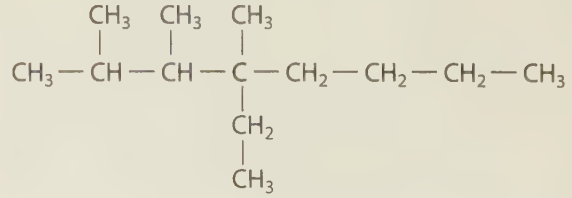
Assess students' knowledge of alkanes by asking them to explain why straight-chain alkanes are considered a homologous series. *(There is a constant increment of change in molecular structure from one compound in the series to the next.)* **Ask** How do straight-chain and branched-chain alkanes differ? *(In branched-chain alkanes, substituents are attached to carbons on the parent chain.)* Then, have students complete the 22.1 Lesson Check.

Reteach



Quiz students orally on the first ten prefixes used in hydrocarbon nomenclature. Then, write the following names on the board: *3-ethylpentane, 2,3,4-trimethylhexane,* and *2,2-dimethylbutane.* Have students write structural formulas for these compounds. Remind students to (1) write the alkane carbon skeleton, (2) attach the substituent groups, and (3) add hydrogen atoms to all the unfilled bonding sites.

Answers



3. **a.** 3-ethylhexane **b.** 2-methylbutane

4. 4-ethyl-2-methylheptane

5.

6.

LESSON 22.2

Key Objectives

DESCRIBE the structural characteristics of alkenes.

DESCRIBE the structural characteristics of alkynes.

Additional Resources

Reading and Study Workbook, Lesson 22.2

Engage

CHEMISTRY & YOU Have students study the photo and read the opening text. Ask students to share what they know about the effects of consuming saturated and unsaturated fats on health. *(Consumption of saturated fats is associated with heart disease, atherosclerosis, and high blood cholesterol levels. Unsaturated fats lower these risks.)*

Activate Prior Knowledge

Assess students' prior knowledge of multiple covalent bonds. **Ask** What kind of bonding occurs between carbon and oxygen in a molecule of CO_2 and between nitrogen atoms in a molecule of N_2? *(a double bond; a triple bond)*

Foundations for Reading

BUILD VOCABULARY Draw students' attention to the terms *alkene* and *alkyne*. Explain that the root that they share with *alkane*, *alk-*, is derived from the word *alkyl*. Point out that this root word indicates that alkenes and alkynes have many of the structural characteristics exhibited by alkanes.

READING STRATEGY Have students make a compare/contrast table for saturated and unsaturated hydrocarbons.

IN ACADEMIC STANDARDS for SCIENCE

C.3.4 Draw structural formulas for and name simple molecules.

C.9.1 Use structural formulas to illustrate carbon atoms' ability to bond covalently to form many different substances.

C.9.2 Identify the variety of molecular types formed by the covalent bonding of carbon atoms and describe the typical properties of these molecular types.

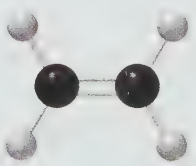
22.2 Unsaturated Hydrocarbons

C.3.4 Structural formulas and names; **C.9.1** Use structural formulas: carbon atoms; **C.9.2** Identify the variety of carbon molecules.

CHEMISTRY & YOU

Q: *What does it mean if a fat is unsaturated?* You've probably read nutrition labels listing saturated and unsaturated fat content. For example, olives are high in unsaturated fat but low in saturated fat. In this lesson, you'll find out what the terms *saturated* and *unsaturated* mean.

Key Questions



What are the structural characteristics of alkenes?

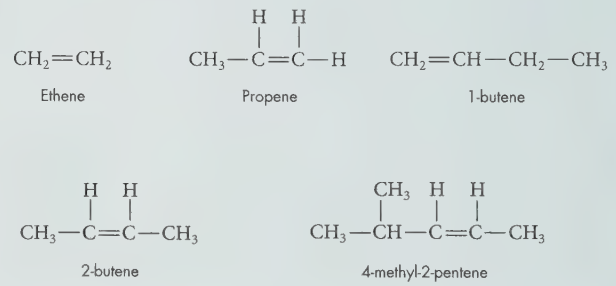
What are the structural characteristics of alkynes?

Vocabulary

- saturated compound
- unsaturated compound
- alkene • alkyne

Figure 22.5 Ethene
Because rotation is restricted around the double bond, atoms in ethene lie in one plane.

CHEMISTRY & YOU



Q: *You just read about saturated and unsaturated compounds. Use what you have learned to describe how saturated and unsaturated fats differ structurally.*

Alkenes

What are the structural characteristics of alkenes?

An organic compound that contains the maximum number of hydrogen atoms per carbon atom is called a **saturated compound.** Alkanes are saturated compounds because the only bonds in alkanes are single covalent bonds. An organic compound that contains double or triple carbon-carbon bonds is called an **unsaturated compound.** The ratio of hydrogen atoms to carbon atoms is lower in an unsaturated compound than in a saturated compound. An **alkene** is a hydrocarbon that contains one or more carbon-carbon double covalent bonds. A carbon-carbon double bond is shown in structural formulas as two parallel lines. **At least one carbon-carbon bond in an alkene is a double covalent bond. Other bonds may be single carbon-carbon bonds and carbon-hydrogen bonds.**

Ethene (C_2H_4) is the simplest alkene. It is often called by the common name ethylene. Figure 22.5 shows the ball-and-stick model of ethene. To name an alkene by the IUPAC system, find the longest chain in the molecule that contains the double bond. This chain is the parent alkene. It has the root name of the alkane with the same number of carbons plus the ending *-ene*. The chain is numbered so that the carbon atoms of the double bond have the lowest possible numbers. Substituents on the chain are named and numbered in the same way they are for alkanes. Some examples of the structures and IUPAC names of simple alkenes are shown below.

Focus on ELL

1 CONTENT AND LANGUAGE Remind students that an *alkane* is a hydrocarbon in which there are only single covalent bonds. Write the words *alkane*, *alkene,* and *alkyne* on the board. Underline the root of each word and circle each suffix. Draw an arrow to the words *single bond*. Guide student to see that the suffix in the names of these compounds tells you the type of bond.

2 FRONTLOAD THE LESSON Have students list the first ten straight-chain alkanes on the board, and review the IUPAC naming rules. Then, have students preview the chemical structures discussed throughout the lesson, noting the similarities between the names of the unsaturated hydrocarbons and their related alkanes.

3 COMPREHENSIBLE INPUT Have students form human models of the hydrocarbons in this lesson. Divide students into three groups, each representing a different class of hydrocarbon: alkane, alkene, alkyne. Provide short lengths of rope to represent the bonds between the atoms and "C" and "H" signs to indicate which students are carbon and hydrogen atoms.

Interpret Graphs

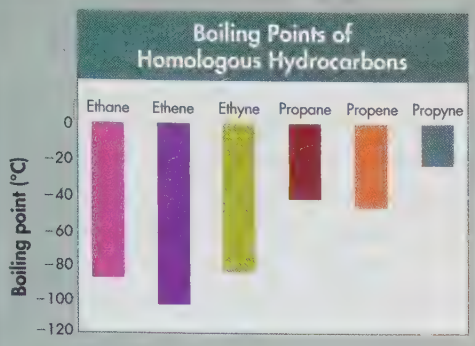


Figure 22.6 The graph shows the relationship between the boiling points and the degree of saturation for some hydrocarbons.

a. Read Graphs Determine the boiling point for each hydrocarbon in the graph.

b. Identify Draw a condensed structural formula for each hydrocarbon.

c. Make Generalizations How does the degree of saturation affect the boiling points of hydrocarbons with the same number of carbon atoms?

Note: The degree of saturation refers to the ratio of hydrogen atoms to carbon atoms.

Alkynes

What are the structural characteristics of alkynes?

A hydrocarbon that contains one or more carbon-carbon triple covalent bonds is called an **alkyne.** A carbon-carbon triple bond is shown in structural formulas as three parallel lines. **At least one carbon-carbon bond in an alkyne is a triple covalent bond. Other bonds may be single or double carbon-carbon bonds and carbon-hydrogen bonds.** Like alkenes, alkynes are unsaturated compounds.

Alkynes are not plentiful in nature. The simplest alkyne is ethyne (C_2H_2), which has the common name acetylene. Acetylene is the fuel burned in oxyacetylene torches used for welding. Figure 22.7 shows that the single bonds that extend from the carbons in the carbon-carbon triple bond of ethyne are separated by an angle of 180°, which makes ethyne a linear molecule.

Like alkanes, the major attractions between alkenes and alkynes are weak van der Waals forces. As a result, the introduction of a double or triple bond into a hydrocarbon does not have a dramatic effect on physical properties such as boiling point. Compare the boiling points for alkanes, alkenes, and alkynes with two and three carbons in Figure 22.6.

Figure 22.7 Ethyne
The triple bond restricts rotation in an ethyne molecule, which has a linear shape.
Identify ***What is the ratio of hydrogen to carbon in ethyne?***

22.2 LessonCheck

14. Review Describe the bonding between atoms in an alkene.

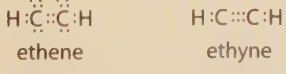
15. Identify What types of bonds are present in an alkyne?

16. Explain What is the difference between saturated and unsaturated hydrocarbons?

17. Make Generalizations How do the boiling points of alkenes and alkynes compare to those of alkanes?

18. Apply Concepts Draw electron dot structures for ethene and ethyne. Use your knowledge of bonding theories to describe the shape of each molecule.

Lesson Check Answers



14. At least one carbon-carbon bond in an alkene is a double bond. Other bonds may be single C–C bonds or C–H bonds.

15. An alkyne contains at least one carbon-carbon triple bond. Other bonds may be single or double C–C bonds or C–H bonds.

16. Saturated hydrocarbons have the maximum number of hydrogen atoms per carbon. Unsaturated hydrocarbons have fewer hydrogen atoms per carbon

17. The boiling points are similar for hydrocarbons with the same number of carbon atoms.

18.

Ethene is planar. Ethyne is linear.

Explain

Alkenes

USE MODELS Direct students to Figures 22.5 and 22.7. Have students compare the models of ethene and ethyne. *(Both molecules have symmetrical carbon atoms that can be superimposed upon one another. In ethene, the carbon atoms are joined by a double bond; in ethyne, by a triple bond. Ethyne has two fewer hydrogen atoms and is linear.)* Then, model the rigidity of the double bond for students. Touch the first fingers of both hands together to represent a single bond, then rotate your hands in opposite directions. Repeat with two fingers of each hand touching, demonstrating that rotation is impossible around a double bond.

CHEMISTRY & YOU Unsaturated fats have double carbon-carbon bonds. All the carbon-carbon bonds in saturated fats are single bonds.

Evaluate

Informal Assessment

Have students explain why hydrocarbons with double or triple bonds are called unsaturated hydrocarbons. Then, have students complete the 22.2 Lesson Check.

Reteach

Have students construct ball-and-stick models of ethane, ethene, and ethyne. Ask students to write and compare the complete structural formulas for the molecules and to describe the molecular geometry of each.

Answers

INTERPRET GRAPHS

a. ethane, –89; ethene, –104; ethyne, –82; propane, –42; propene, –47; propyne, –23

b. CH_3CH_3, $CH_2{=}CH_2$, $CH{\equiv}CH$, $CH_3CH_2CH_3$, $CH_2{=}CHCH_3$, $CH{\equiv}CCH_3$

c. For hydrocarbons with the same number of carbons, the boiling points are similar.

FIGURE 22.7 1:1

Explain

CHEMISTRY & YOU Have students read the feature and examine the photographs.

An arson investigator can often tell by the burn markings at a fire scene if an accelerant was used. The use of an accelerant is typical in arson-related fires because it makes a fire burn hotter and longer than normal, producing the most damage in a short period of time. Most accelerants used by an arsonist are organic compounds containing mixtures of hydrocarbons. Pose the following challenge to students: *Imagine that you are investigating a suspected arson fire in a wood-framed building. Use your knowledge of hydrocarbons to search for signs that an accelerant was used.* You may need to guide students in the following ways:

- Liquids tend to seek the lowest level in a structure.
- Hydrocarbons burn faster and hotter than wood.
- Hydrocarbons cannot ignite spontaneously.
- Hydrocarbons are not miscible in water.
- Hydrocarbon vapors are heavier than air and flow downward.
- Many hydrocarbons are powerful solvents.

Extend

Connect to TECHNOLOGY

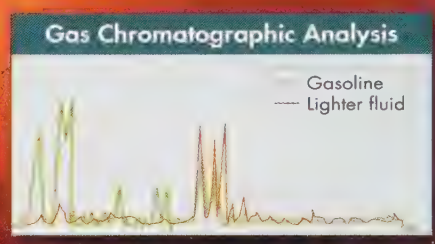
Explain that as accelerants evaporate, the hydrocarbons vaporize into the air space above the remaining ash. Explain that one of the most advanced techniques for detecting accelerants is gas chromatography, a technique used to separate volatile organic compounds into specific hydrocarbons. Tell students that once the likely ignition point of the fire has been located, samples of solid debris are collected from the area and placed in an airtight container to prevent evaporation. The container is then heated, releasing any hydrocarbons into the trapped space above the sample. A needle is inserted through the top of the container to remove a sample of the hydrocarbons and then injected into the chromatography equipment for separation and analysis. The result identifies each specific compound of the gas mixture, and if the compounds are hydrocarbons, the determination of the crime of arson can be confirmed.

Answers

TAKE IT FURTHER

1. $CH_3CH_2CH(CH_3)CH_2CH_3$
2. Gasoline contains a wider range of compounds, with a majority of lighter compounds. Lighter fluid consists of a narrower range of compounds, which are in the heavier range.

CHEMISTRY & YOU: CAREERS



Arson Investigator

Arson is a dangerous crime in which a person starts a fire with the intent to cause property damage or to harm another person. The person responsible, an arsonist, often uses an accelerant to initiate the fire. Gasoline and lighter fluid—both ignitable fluids composed of hydrocarbons—are two of the most commonly used accelerants. If arson is suspected, an arson investigator carefully examines the fire scene and looks for evidence of a crime.

Arson investigators often collect debris from the scene to take back to the laboratory to analyze for accelerants. Investigators frequently analyze the samples with an instrument called a gas chromatograph. The output of the analysis is sometimes called a "fingerprint" because, like a human fingerprint, each accelerant shows a characteristic pattern. With the knowledge of the molecules in each accelerant, the investigator can identify the accelerant from the fingerprint. Knowing which accelerant was used in the crime can help police narrow the search for the arsonist.

WHO'S YOUR PARTNER? Trained dogs with keen noses are often used to guide the evidence collection.

ACCELERANTS Gasoline and lighter fluid are complex mixtures of hydrocarbons. Each peak in the chromatograph represents a different chemical compound.

Take It Further

1. Describe One of the hydrocarbons found in gasoline is the branched-chain alkane 3-methylhexane. Write the condensed structural formula for this compound.

2. Analyze Data Use the data in the gas chromatographic analysis above to compare the number of hydrocarbon compounds in gasoline and lighter fluid.

Differentiated Instruction

ELL ENGLISH LANGUAGE LEARNERS Relate the word *accelerant* to *accelerate*. Act them out to visually show that both words imply to go faster, to hasten, to move quickly, to speed up, and then act out the opposite meaning, slowing down.

LPR LESS PROFICIENT READERS Have students hypothesize why there is a dog in the photograph of a fire scene. Then, ask these students to perform an Internet search on arson dogs and to orally explain what they learned.

L3 ADVANCED STUDENTS Have students compile a list of hydrocarbons typically found in liquid fuel and determine the properties of these compounds that allow for the separation and identification with the gas chromatography equipment.

22.3 Isomers

C.3.4 Structural formulas and names; C.9.1 Use structural formulas: carbon atoms; C.9.2 Identify the variety of carbon molecules.

CHEMISTRY & YOU

Q: *How do isomers help you see?* Like many other biological processes, vision involves chemistry. Light entering the eye causes a change in the three-dimensional structure of retinal molecules in your eye. The overall structure of retinal molecules appears bent before the light strikes; afterward the structure appears relatively straight. This structural change results in vision.

Key Questions

How do the properties of constitutional isomers differ?

What are two types of stereoisomers?

Vocabulary

- isomer
- constitutional isomer
- stereoisomer
- *cis-trans* isomer
- *cis* configuration
- *trans* configuration
- asymmetric carbon
- enantiomer

Constitutional Isomers

How do the properties of constitutional isomers differ?

You may have noticed that the structures of some hydrocarbons differ only in the positions of substituents or of multiple bonds. Look at the structural formulas for butane and 2-methylpropane and at the models in Figure 22.8.

$$CH_3—CH_2—CH_2—CH_3$$

Butane (C_4H_{10}) (bp −0.5°C)

$$CH_3—\underset{\displaystyle CH_3}{\underset{|}{CH}}—CH_3$$

2-methylpropane (C_4H_{10}) (bp −11.7°C)

Even though both compounds have the formula C_4H_{10}, their boiling points and other properties differ. Because their structures are different, they are different substances. Compounds that have the same molecular formula but different molecular structures are called **isomers.**

Butane and 2-methylpropane represent a category of isomers called constitutional isomers, or structural isomers. **Constitutional isomers** are compounds that have the same molecular formula, but the atoms are joined together differently. **Constitutional isomers differ in physical properties such as boiling point and melting point. They also have different chemical reactivities.** In general, the more highly branched the hydrocarbon structure is, the lower the boiling point of the isomer will be compared with less branched isomers.

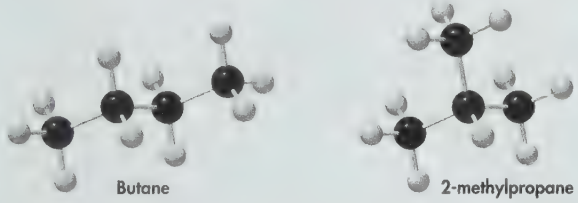


Figure 22.8 Constitutional Isomers
Both butane and 2-methylpropane have the molecular formula C_4H_{10}. But the atoms in each compound are arranged differently.

Focus on ELL

1 CONTENT AND LANGUAGE Write the term *asymmetric carbon* on the board, and pronounce it for the class. Remind students that in biology, animals that exhibit symmetry have body parts that are mirror images of each other if the animal is divided in half by an imaginary plane. Explain that the prefix *a-* means "without," so an asymmetric carbon is a carbon with four different molecules attached to it.

2 FRONTLOAD THE LESSON Demonstrate that one of your hands is the mirror image of the other when placed with palms together. Then, have students place both hands palm down and overlap them. Point out that in this position their hands are not mirror images of each other, so they are not *superimposable* on each other. Tell students to keep this activity in mind as they discuss asymmetric carbons.

3 COMPREHENSIBLE INPUT Use ball-and-stick models to demonstrate the isomers in Figures 22.8, 22.9, and 22.10. Provide students with enough balls and sticks to create butane and *trans*-2-pentene, and have them practice rearranging the structures to form each molecule's isomers.

LESSON 22.3

Key Objectives

EXPLAIN how the properties of constitutional isomers differ.

IDENTIFY two types of stereoisomers.

Additional Resources

- Reading and Study Workbook, Lesson 22.3

PearsonChem.com

Engage

CHEMISTRY & YOU Have students read the introduction. Explain that retinal is a molecule in the rod and cone cells of the retina. Retinal straightens when it is excited by light energy. **Ask** What information does the three-dimensional structure of a molecule reveal? *(how its atoms are arranged in space)*

Build Background

Bring a folded folding chair to class and show it to students. **Ask** What will happen to the structure of this chair if I open it? *(It will change.)* **Ask** Will opening the chair change the kinds of atoms in the chair? *(no)* Point out that opening or folding the chair is an analogy for isomerization. Tell students to keep this analogy in mind as they proceed with the lesson.

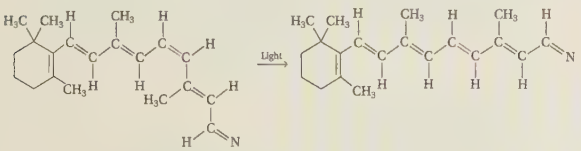
Foundations for Reading

BUILD VOCABULARY Explain that *isomers*, is Greek for "equal parts." **Ask** What is another chemical term that begins with the prefix *iso-*? What does it mean? *(isotopes; atoms of the same elements with different masses)*

IN ACADEMIC STANDARDS for SCIENCE

- Use analogies and models (mathematical and physical) to simplify and represent systems that are difficult to understand or directly experience due to their size, time scale, or complexity, and recognize the limitations of analogies and models.

C.9.1 Use structural formulas to illustrate carbon atoms' ability to bond covalently to form many different substances.



Also covered C.3.4, C.9.2.

Explain

Constitutional Isomers

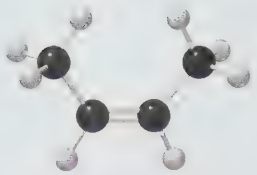
START A CONVERSATION Point out that the number of possible constitutional isomers for an alkane increases dramatically with increasing numbers of carbon atoms. Explain that with more carbon atoms, there are more ways to arrange the atoms in space. Remind students that each isomer has a unique set of physical and chemical properties. Point out that the existence of isomers is a major reason that so many different organic compounds exist.

CHEMISTRY & YOU Cis-trans isomerism aids in vision. Before light strikes, the retinal structure is in the cis configuration and appears bent because the R groups consist of multiple carbon chains. Likewise, after the light strikes, the retinal structure appears straight.

cis configuration — *trans* configuration

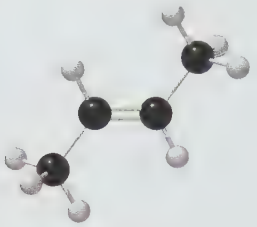
Explore

Class Activity



PURPOSE Students use models to identify isomers.

PROCEDURE Have students use model kits to construct isomers of pentane (C5H12) and hexane (C6H14). Have them draw the structural formula for each isomer. **Ask** How does the number of pentane isomers compare with the number of hexane isomers? (There are more hexane isomers.)



Explain

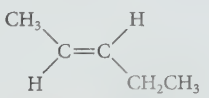
Stereoisomers

USE VISUALS Point out that the number of possible isomers for an alkene can be greater than for an alkane. Draw the complete structural formulas of 1-butene, *cis*-2-butene, and *trans*-2-butene on the board to show the three possible isomers for butene (C_4H_8). Introduce the term cis-trans *isomers* and explain how *cis*-2-butene and *trans*-2-butene are different molecules due to the lack of free rotation about the carbon-carbon double bond.

Cis configuration

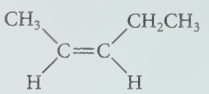
Trans configuration

Figure 22.9 *Cis-Trans* Isomers
The properties of *cis-trans* isomers are different. The boiling point of *cis*-2-butene is 3.7°C, and the boiling point of *trans*-2-butene is 0.8°C.
Compare *How are the cis and trans configurations different?*



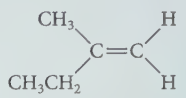
Stereoisomers

What are two types of stereoisomers?



Remember that molecules are three-dimensional structures. So molecules with the same molecular formula and with atoms joined in exactly the same order may still be isomers. **Stereoisomers** are molecules in which the atoms are joined in the same order, but the positions of the atoms in space are different. **Two types of stereoisomers are *cis-trans* isomers and enantiomers.**

Cis-Trans Isomers A double bond between two carbon atoms prevents other atoms in the molecule from rotating, or spinning, with respect to each other. Because of this lack of rotation, groups on either side of the double bond can have different orientations in space. ***Cis-trans* isomers,** also known as geometric isomers, have atoms joined in the same order, but the spatial orientation of the groups differs. Although *cis-trans* isomerism is possible in other molecules, the most common example occurs in molecules with double bonds. Look at the models of 2-butene in Figure 22.9. Two arrangements are possible for the methyl groups and hydrogen atoms with respect to the rigid double bond. In the ***cis* configuration,** similar groups are on the same side of the double bond. But, when similar groups extend from opposite sides of the double bond, the isomer is in the ***trans* configuration.** *Cis-trans* isomers have different physical and chemical properties.



You should be able to identify *cis-trans* isomers of alkenes when each carbon of the double bond has one substituent and one hydrogen. Notice that the substituent groups attached to the carbons of the double bond do not need to be the same as illustrated in the structures below.

trans-2-pentene

cis-2-pentene

2-methyl-1-butene
(no *cis*, *trans* isomers)

Enantiomers The second category of stereoisomerism occurs whenever a central atom has four different atoms or groups attached. Most commonly the central atom is carbon. A carbon with four different atoms or groups attached is an **asymmetric carbon.** Look at the molecular models in Figure 22.10. Because H, F, Cl, and Br atoms are attached to a single carbon atom, the carbon is an asymmetric carbon. The relationship between the two molecules is similar to the relationship between right and left hands. Sometimes the terms *right-handed* and *left-handed* are used to describe compounds with an asymmetric carbon.

Figure 22.10 Asymmetric Carbons
When a carbon atom has four different substituents, as in the compound CHFClBr, it is an asymmetric carbon. Molecules with an asymmetric carbon are either right-handed or left-handed and cannot be superimposed.

See molecules with asymmetric carbons online.

Differentiated Instruction

L1 STRUGGLING STUDENTS Create ball-and-stick models of various constitutional isomers and *cis-trans* isomers. Have students practice identifying the type of isomer and in the case of a *cis-trans* isomer, the configuration.

ELL ENGLISH LANGUAGE LEARNERS Have students create flashcards for the vocabulary terms. On the front side, students should write the term. On the back, students should write the definition and draw an example structure.

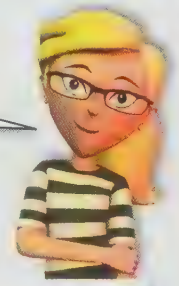
L3 ADVANCED STUDENTS Have students research the origin of the International Union of Pure and Applied Chemistry (IUPAC). Tell them to find out when, where, and why the first international congress was held. Findings should be presented in a written report.

To understand the stereoisomerism that involves asymmetric carbons, you need to visualize the relationship between an object and its mirror image. If the object is symmetrical, like a ball, then its mirror image can be superimposed. That is, the appearance of the ball and its reflection are indistinguishable. By contrast, a pair of hands is distinguishable even though the hands have identical parts. The right hand reflects as a left hand, and the left hand reflects as a right hand. When you try to stack your hands on top of one another, the thumb of one hand lines up with the little finger of the other hand. No matter how you turn your hands, you can't get them to look exactly alike.

Pairs of molecules that are mirror images and not superimposable are called **enantiomers,** or optical isomers. The molecules shown in Figure 22.10 are examples of enantiomers. Unlike other isomers, enantiomers have identical physical properties such as boiling points and densities. Enantiomers do, however, behave differently when they interact with other molecules that have asymmetric carbons. In Chapter 24, you will learn that many molecules in your body have asymmetric carbons. As a result, each enantiomer can have a different effect on the body.

CHEMISTRY & YOU

Q: *What kind of isomerism aids in vision? Look at Figure 22.9. Explain how the overall structure of a retinal molecule would appear relatively straight or bent depending on which cis-trans isomer it is.*



SampleProblem 22.4

Identifying Asymmetric Carbon Atoms

Which compound has an asymmetric carbon?

a. CH_3CHCH_3 (OH) **b.** $CH_3CHCH_2CH_3$ (OH)

The central carbon in compound (a) has two CH_3 groups attached, so the carbon is not asymmetric.

1 Analyze **Identify the relevant concepts.**

An asymmetric carbon has four different substituents attached.

2 Solve **Apply the concepts to this problem.**

Draw the structure in a way that makes it easier to compare the four different groups attached to the central carbon.

a. $CH_3-\underset{\displaystyle OH}{\overset{\displaystyle H}{\underset{|}{\overset{|}{C}}}}-CH_3$ ✗

b. $CH_3-\underset{\displaystyle OH}{\overset{\displaystyle H}{\underset{|}{\overset{|}{C}}}}-CH_2CH_3$ ✓

Compare the groups. If all four groups are unique, the central carbon is asymmetric. If any two are the same, the central carbon is not asymmetric.

Compound (b) has an asymmetric carbon.

19. Identify the asymmetric carbon, if any, in each of the following compounds:

a. CH_3CHCHO (Cl) **b.** CH_3CHOH (CH_3)

20. Identify any asymmetric carbons in the following compounds:

a. $CH_3CH_2-\underset{\displaystyle F}{\overset{\displaystyle CH_3}{\underset{|}{\overset{|}{C}}}}-Br$ **b.** CH_2Cl_2

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of two to complete the lab. Be sure to pair ELLs with writing/reading partners so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Create drawings of the structural formulas of the nine different constitutional isomers of heptane, utilizing color to emphasize the differences.

INTERMEDIATE: LOW/HIGH Orally question students about their findings. Use the terms *right-handed* and *left-handed* when asking questions about asymmetric carbon.

ADVANCED

LOW Have students write draft explanations and answers to the questions from the lab and then revise their answers after consultation with you.

HIGH Ask students to complete the Analyze and Conclude questions with clearly displayed, written responses. Post their responses for other students' refererence.

Explore

TeacherDemo

PURPOSE Students observe three-dimensional models of enantiomers.

MATERIALS two ball-and-stick models of CHFClBr

PROCEDURE Demonstrate how it is not possible to superimpose one model on the other.

Explain

MAKE A CONNECTION Tell students that mirror images exist in nature. For example, 99 percent of the shells of some snail species are right-handed spirals and 1 percent are left-handed spirals. The right- and left-handed spirals are mirror images. Other species have shells that are normally left-handed.

Sample Practice Problem

Determine if 2-chloropropane has an asymmetric carbon. *(no)*

Answers

FIGURE 22.9 The groups are on opposite sides of the double bond in the *trans* configuration; the groups are on the same side of the bond in the *cis* configuration.

19. a. $CH_3-\overset{\displaystyle H}{\underset{|}{\overset{|}{C^*}}}-CHO$ (Cl)

b. no asymmetric carbon

20. a. $CH_3CH_2-\overset{\displaystyle CH_3}{\underset{|}{\overset{|}{C^*}}}-Br$ (F)

b. no asymmetric carbon

Explore

Isomers

QuickLab

PURPOSE After completing this activity, students will be able to build ball-and-stick models of heptane isomers and name them.

SKILLS FOCUS using models, observing, analyzing

EXPECTED OUTCOMES Students will model and name nine constitutional isomers of heptane.

PREP TIME 5 minutes

CLASS TIME 25 minutes

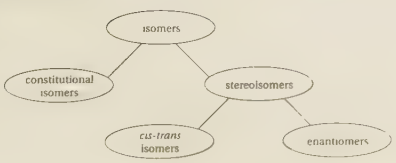
ANALYZE AND CONCLUDE

1. heptane, 2-methylhexane, 3-methylhexane, 2,3-dimethylpentane, 2,4-dimethylpentane, 2,2-dimethylpentane, 3,3-dimethylpentane, 3-ethylpentane, 2,2,3-trimethylbutane
2. 4
3. Each is a unique compound.
4. 3-methylhexane and 2,3-dimethylpentane

ENRICHMENT Students can model, draw, and name the 18 constitutional isomers of octane.

Evaluate

Informal Assessment



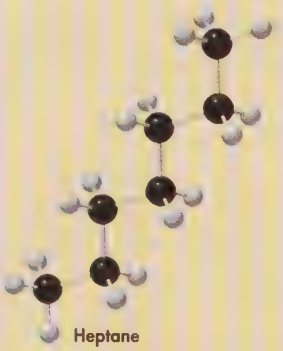
Have students verbally explain what the term *isomer* means and then describe the differences among constitutional isomers, *cis-trans* isomers, and *enantiomers* in 60 seconds or less. Ask students to draw an example of each type of isomer. Then have students complete the 22.3 Lesson Check.

Reteach

Use ball-and-stick models to visually explain the requirements for classifying two molecules with the same molecular formula as constitutional isomers, *cis-trans* isomers, or enantiomers.

Answer

27.



QuickLab

Isomers of Heptane

Purpose To build ball-and-stick models and name the nine constitutional isomers of heptane (C_7H_{16})

Materials

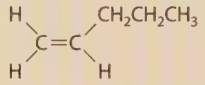
- **ball-and-stick molecular model kit** (Colors used to represent elements in the kit may not match colors used to represent elements in this book.)
- **pencil and paper**

Heptane

Procedure

1. Build a model for the straight-chain isomer of C_7H_{16}. Draw the structural formula for this isomer.
2. Remove one carbon atom from the end of the chain and reattach it as a methyl substituent to form a branched-chain alkane. Draw the structural formula for this isomer.
3. Move the methyl group to a new position on the chain. Then draw this third isomer. Is there another position that the methyl group can be placed on the chain of six carbons to form yet another isomer?
4. Make other constitutional isomers by shortening the longest straight chain and using the removed carbons as substituents. Draw the structural formulas for each isomer.

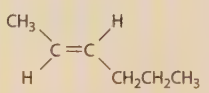
Analyze and Conclude



1. **List** What are the names of the nine constitutional isomers of C_7H_{16}?
2. **Identify** What is the shortest possible straight carbon chain in the group of heptane isomers?
3. **Explain** Why does each constitutional isomer have its own unique name?
4. **Use Models** Look carefully at the structural formulas you drew for the nine constitutional isomers. Identify any that have an asymmetric carbon.

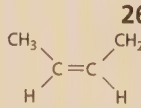
22.3 LessonCheck

21. **Explain** Why would you expect two constitutional isomers to have different properties such as boiling points?
22. **Review** Name two types of stereoisomers.
23. **Apply Concepts** Draw structural formulas for the following alkenes. If a compound has *cis-trans* isomers, draw both the *cis* and *trans* forms.
    a. 1-pentene
    b. 2-hexene
    c. 2-methyl-1-butene
    d. 2,5-dimethyl-3-hexene
24. **Compare** How are constitutional isomers and stereoisomers similar? How are they different?
25. **Explain** How can you identify an asymmetric carbon?
26. **Use Analogies** Think of an analogy to describe the relationship between two molecules that are enantiomers.
27. **Summarize** Draw a concept map to show how the following vocabulary words are related: isomers, constitutional isomers, stereoisomers, *cis-trans* isomers, and enantiomers.



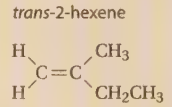
Lesson Check Answers

21. Constitutional isomers are different compounds with different physical properties.
22. *cis-trans* isomers and enantiomers
23. a.

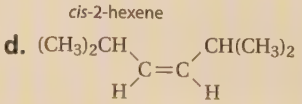


1-pentene

b.

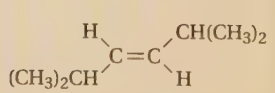


trans-2-hexene



cis-2-hexene

c.



2–methyl–1–butene

d.

cis-2,5-dimethyl-3-hexene

trans-2,5-dimethyl-3-hexene

24. Both types of isomers have the same molecular formula but different molecular structures. Constitutional isomers differ in the order the atoms are joined; stereoisomers differ in the way the atoms are arranged in space.
25. It has four different substituents.
26. Answers will vary.

22.4 Hydrocarbon Rings

C.3.4 Structural formulas and names; C.9.1 Use structural formulas: carbon atoms; C.9.2 Identify the variety of carbon molecules.

CHEMISTRY & YOU

Q: *Does a compound have to be smelly in order to be classified as aromatic?* When you hear the word *aromatic*, you may think of perfume or flowers. But in organic chemistry, *aromatic* means something else.

Key Questions

What is the general structure of a cyclic hydrocarbon?

What is the most accurate description of bonding in benzene?

Vocabulary

- cyclic hydrocarbon
- cycloalkane
- aromatic compound
- aliphatic compound

Cyclic Hydrocarbons

What is the general structure of a cyclic hydrocarbon? Not all hydrocarbons are straight chains or branched chains. **In some hydrocarbon compounds, the carbon chain is in the form of a ring.** A compound that contains a hydrocarbon ring is called a **cyclic hydrocarbon.** Figure 22.11 shows the structures of some examples. Many molecules found in nature contain cyclic hydrocarbons. Rings with five and six carbons are the most abundant.

Just as straight-chain and branched-chain alkanes can be either saturated or unsaturated, so can cyclic hydrocarbons. A cyclic hydrocarbon that contains only single bonds, and is therefore saturated, is called a **cycloalkane.** To determine the IUPAC name of a cycloalkane, first count the number of carbons in the ring and assign the corresponding alkane name. Then simply add the prefix *cyclo-* to the alkane name. For example, the three-carbon ring in Figure 22.11 is named cyclopropane.

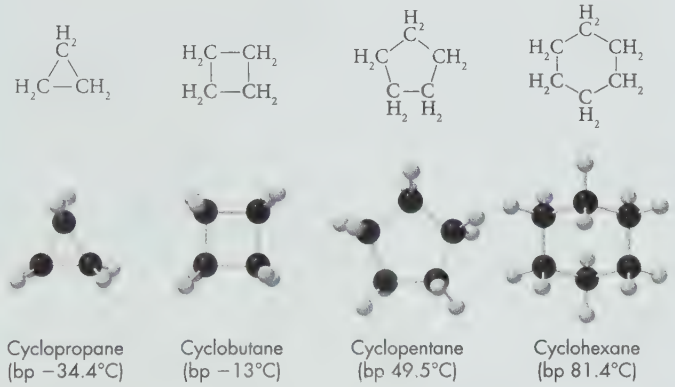


Figure 22.11 Cycloalkanes These illustrations show the first four members of the homologous series of cycloalkanes.
Predict ***How would you expect the boiling point of cycloheptane to compare to the boiling points of these cycloalkanes?***

Focus on ELL

1 CONTENT AND LANGUAGE Begin the lesson by writing the root word *cycl* on the board. Assign students to groups and ask them to create a list of words using this root word. *(Sample answers:* bicycle, cyclical, cycle, motorcycle, tricycle, cyclone*)* Explain that *cycl* means "circle, wheel, or circular." Have students predict the meaning of the vocabulary terms *cyclic hydrocarbon* and *cycloalkane*.

2 FRONTLOAD THE LESSON Have students preview the models and structural formulas of the featured hydrocarbons. Discuss how these visuals differ from the other representations of hydrocarbons learned in prior lessons.

3 COMPREHENSIBLE INPUT Show students digital three-dimensional models of the structures in this lesson. Then have students create physical models of benzene by using foam balls and pipe cleaners, or pretzel sticks and marshmallows.

LESSON 22.4

Key Objectives

IDENTIFY the general structure of a cyclic hydrocarbon.

DESCRIBE bonding in a benzene ring.

Additional Resources

- Reading and Study Workbook, Lesson 22.4

PearsonChem.com

Engage

CHEMISTRY & YOU Explain that *aromatic* comes from a Greek word meaning "sweet spice." Tell students that aromatherapy is the use of aromatic oils for their supposed therapeutic effects when applied to the skin or inhaled. Predict why scientists used the name *aromatic* to describe a particular type of hydrocarbon.

Build Background

Allow students to handle models representing 6 carbon atoms and 12 hydrogen atoms as you begin the lesson. **Ask** How could you form a ring or a circle with these atoms, rather than a chain? *(The two carbons at the end of the chain could bond to one another.)*

Foundations for Reading

BUILD VOCABULARY Explain that the prefixes *ortho-*, *meta-*, and *para-* used to name some aromatic compounds are all derived from Greek, meaning "straight or correct," "beyond or after," and "beside of or alongside of," respectively.

READING STRATEGY Have students use a Venn diagram to compare and contrast aliphatic cyclic hydrocarbons and aromatic cyclic hydrocarbons.

IN ACADEMIC STANDARDS for SCIENCE

C.3.4 Draw structural formulas for and name simple molecules.

C.9.2 Identify the variety of molecular types formed by the covalent bonding of carbon atoms and describe the typical properties of these molecular types.

Also covered C.9.1

Answers

FIGURE 22.11 It should be higher (118°C)

Explain

Cyclic Hydrocarbons

USE VISUALS Have students examine Figure 22.11. **Ask** Why does cyclohexane have two fewer hydrogen atoms than hexane? *(When carbon atoms at the end of a chain bond to form a ring, the atoms can form only two additional bonds instead of three.)*

APPLY CONCEPTS Point out that the formation of a ring causes bond strain in all cycloalkanes with rings that contain fewer than six carbons. The bond angle in these cycloalkanes tends to be less than the normal carbon-carbon bond angle of 109.5°. Explain that bond strain explains the increased chemical reactivity of small-ring cycloalkanes.

Aromatic Hydrocarbons

CHEMISTRY & YOU Aromatic compounds contain benzene or another ring that has bonding like that of benzene. Bonding in benzene and other aromatic compounds is special in that the bonding electrons between ring members are shared evenly around the ring.

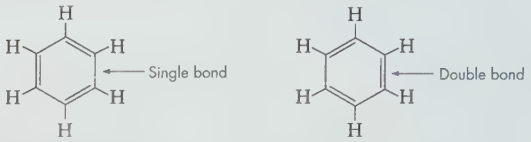
Extend

The concept of benzene as a hybrid of two conventional structures was a major breakthrough in chemistry. Using a CAD program or an actual three-dimensional model, show students that the benzene ring structure consists of σ bonds formed from overlap of sp^2 hybrid orbitals on the neighboring carbon atoms. Point out how the unhybridized carbon p_z orbitals project above and below the plane of the ring. Describe how, in theory, the lobes of the orbitals join to form the circular rings of electron density above and below the plane. These rings make up the other part of the carbon-carbon double bond in benzene. The two forms of this ring represent the total resonance of the system. Have students investigate Kekulé structures and describe and draw how these structures relate to the concepts in this lesson.

Figure 22.12 Benzene
All the atoms in the aromatic compound benzene lie in a single plane.
Use Models *What is the molecular formula for benzene?*

CHEMISTRY & YOU

Q: *You just read about aromatic compounds. Can you explain to a classmate what it means if a compound is aromatic?*



Aromatic Hydrocarbons

What is the most accurate description of bonding in benzene?

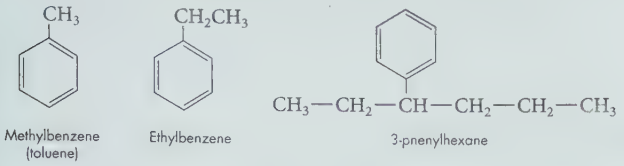
There is a class of unsaturated cyclic hydrocarbons that are responsible for the aromas of spices such as vanilla, cinnamon, cloves, and ginger. These compounds were originally called aromatic compounds because they have distinct, pleasant aromas. However, not all compounds classified as aromatic have pleasant odors. In fact, many do not have an odor at all.

Benzene is the simplest aromatic compound. An **aromatic compound,** or arene, is now defined as an organic compound that contains a benzene ring or other ring in which the bonding is like that of benzene. Any compound not classified as an aromatic compound is an **aliphatic compound.** The compounds you studied earlier in this chapter—alkanes, alkenes, alkynes, and cycloalkanes—are aliphatic compounds. The properties of aromatic compounds are quite different from those of aliphatic compounds.

The Structure of Benzene Friedrich Kekulé (1829–1896) made a major contribution to chemistry. He was the first to describe the structure of a benzene molecule. Look at the models of benzene shown in Figure 22.12. The benzene molecule is a six-membered carbon ring with one hydrogen atom attached to each carbon. This arrangement leaves one electron from each carbon free to participate in a double bond. Two different structures with alternating double bonds can be written for benzene.

These structural formulas show only the extremes in electron sharing between any two adjacent carbons in benzene. One extreme is a normal single bond. The other extreme is a normal double bond. Recall that when two or more equally valid structures can be drawn for a molecule, resonance occurs. The actual bonding in a benzene ring doesn't alternate between the two extreme resonance structures. Rather, all the bonds in the ring are identical hybrids of single and double bonds. **In a benzene molecule, the bonding electrons between carbon atoms are shared evenly around the ring.** Benzene and other molecules that exhibit resonance are more stable than similar molecules that do not exhibit resonance. Thus, benzene is not as reactive as six-carbon alkenes.

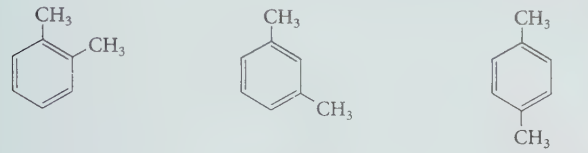
Drawing a solid or dashed circle inside a hexagon is a good way to represent benzene in terms of how the electrons are distributed. However, such a drawing does not show the number of electrons involved. For this reason, the traditional structure, shown at the far right in the series below, is used in this textbook. Remember, though, that each bond in the ring is identical.



Differentiated Instruction

L1 STRUGGLING STUDENTS Have students summarize the lesson in a main-ideas-and-details chart. Check their charts for accuracy and suggest corrections where needed.

LPR LESS PROFICIENT READERS Have students restate the definitions of *aromatic compound* and *aliphatic compound* in their own words. Encourage students to list an example of each type of compound and explain why the example fits into its classification.



L3 ADVANCED STUDENTS Challenge students to draw the electron dot structure for benzene. Completed structures should include both resonance forms of benzene.

Substituted Aromatic Compounds Many dyes used to produce the intense colors of your clothing, such as the blue shown in Figure 22.13 are substituted aromatic compounds. Compounds containing substituents attached to a benzene ring are named using benzene as the parent hydrocarbon. When the benzene ring is a substituent, the C_6H_5 group is called a phenyl group.

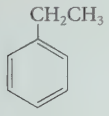
Methylbenzene (toluene) | Ethylbenzene | 3-pnenylhexane

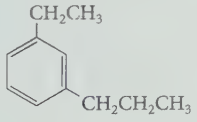
Some derivatives of benzene have two substituents. These derivatives are called disubstituted benzenes. Dimethylbenzene, also called xylene, is an example of a disubstituted benzene. There are three constitutional isomers for dimethylbenzene ($C_6H_4(CH_3)_2$). The boiling points of the three compounds are a reminder that constitutional isomers have different physical properties.

1,2-dimethylbenzene (o-xylene) (bp 144°C) | 1,3-dimethylbenzene (m-xylene) (bp 139°C) | 1,4-dimethylbenzene (p-xylene) (bp 138°C)

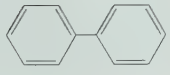
In the IUPAC naming system, the possible positions of two substituents in disubstituted benzene are designated as 1,2; 1,3; or 1,4. Common names for disubstituted benzenes use the terms *ortho*, *meta*, and *para* (abbreviated as *o*, *m*, and *p*) in place of numbers.

Figure 22.13 Dyes
Many dye molecules have phenyl groups. For example, indigo, which is used to color blue jeans, has two phenyl groups.





22.4 LessonCheck



28. **Define** What is a cyclic hydrocarbon?

29. **Review** Describe the bonding between carbon atoms in benzene.

30. **Identify** Name the following compounds using the IUPAC system.

a. 

c. 

b. 

31. **Evaluate** The alternate name for an aromatic compound is arene. Do you think arene is a good option? Consider what the suffix *-ene* means when used with aliphatic compounds.

BIGIDEA CARBON CHEMISTRY

32. Hexane, 1-hexene, cyclohexane, and benzene each have six carbon atoms. What is the difference between these hydrocarbons? Use the words *aliphatic*, *aromatic*, *saturated*, and *unsaturated* to explain your answer.

Lesson Check Answers

28. In a cyclic hydrocarbon, the carbon chain is in the form of a ring.

29. In benzene, the bonding electrons between carbon atoms are shared evenly around the ring.

30. **a.** ethylbenzene
b. 1-ethyl-3-propylbenzene
c. phenylbenzene

31. The suffix *-ene* indicates the presence of a double bond, but the bonds in the rings in aromatic compounds are hybrid bonds, not alternating single and double bonds.

32. **BIG**IDEA Hexane is a straight-chain, aliphatic, saturated hydrocarbon. 1-hexene is a straight-chain, aliphatic, unsaturated hydrocarbon. Cyclohexane is a cyclic, aliphatic, saturated hydrocarbon. Benzene is an aromatic hydrocarbon, which is unsaturated, by definition.

Explain

START A CONVERSATION Compare the structure of benzene to that of a hexagon. Remind students that the prefix *hex-* indicates six and *hexagon* means "six-sided polygon." Show students that the benzene ring consists of six carbon atoms bonded in a flat hexagonal ring. Point out that each carbon is bonded to only one hydrogen atom because of the three alternating double bonds. Ask students to describe the molecular geometry at each carbon atom. *(It is trigonal planar.)*

Extend

Have students draw and present to the class six examples of disubstituted benzenes. Students should present the names of the compounds as well as a summary list explaining how to name them.

Evaluate

Informal Assessment

To asses students' understanding of the lesson, ask them to create a compare-and-contrast table and complete it for each set of terms in relation to hydrocarbons.

1. *aromatic* and *aliphatic*

2. *chain* and *cyclic*

3. *saturated* and *unsaturated*

Then, have students complete the 22.4 Lesson Check.

Reteach

As a class, create a concept map to help clarify relationships and characteristics of the various types of hydrocarbons learned in this lesson. If students are still struggling, include on the concept map the relationships and characteristics of all the hydrocarbons learned in this chapter.

Answers

FIGURE 22.12 C_6H_6

LESSON 22.5

Key Objectives

- **IDENTIFY** hydrocarbons found in natural gas.
- **DESCRIBE** the first step in the refining of petroleum.
- **CLASSIFY** coal.

Additional Resources

- Reading and Study Workbook, Lesson 22.5

PearsonChem.com

Engage

CHEMISTRY & YOU Have students read the introduction. Have students share what they know about gasoline. *(Sample answers: mixture of alkanes, flammable, volatile)* **Ask** Do you think gasoline occurs naturally or do you think it is a manufactured product? *(Answers will vary.)* Explain that gasoline is not manufactured, but it must go through a refining process before it can be used as a vehicular fuel.

Build Background

Relate the chemical process of cracking in a petroleum refinery to the physical process when an object cracks or breaks apart.

Foundations for Reading

BUILD VOCABULARY Explain that the word *petroleum* was created by combining the Latin word for oil, *oleum*, with the Greek prefix *petr-*, meaning "stone."

22.5 Hydrocarbons From Earth's Crust

CHEMISTRY & YOU

Q: *Where does gasoline come from?* You might think gasoline comes from the gas station, but what about before that? In this lesson, you'll find out where gasoline comes from and how it is refined.

Key Questions

- *What hydrocarbons are in natural gas?*
- *What is the first step in the refining of petroleum?*
- *What characteristics are used to classify coal?*

Vocabulary

- cracking

Natural Gas

What hydrocarbons are in natural gas?

The burning of fossil fuels produces much of the world's energy. Fossil fuels are carbon based because they are derived from the decay of organisms. Millions of years ago, marine organisms died, settled on the ocean floor, and were buried in ocean sediments. Heat, pressure, and bacteria changed the residue into petroleum and natural gas, which contain mostly aliphatic hydrocarbons. Figure 22.14 shows how natural gas is often found overlaying oil deposits or in separate pockets in rock.

Natural gas is an important source of alkanes of low molar mass. Typically, natural gas is composed of about 80 percent methane, 10 percent ethane, 4 percent propane, and 2 percent butane. The remaining 4 percent consists of nitrogen and hydrocarbons of higher molar mass. Natural gas also contains a small amount of the noble gas helium. In fact, natural gas is a major source of helium. Methane, the major constituent of natural gas, is especially prized for combustion because it burns with a hot, clean flame.

$$CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(g) + \text{heat}$$

Propane and butane are separated from the other gases in natural gas by liquefaction. These heating fuels are sold in liquid form in pressurized tanks as liquid petroleum gas (LPG).

Oxygen is necessary for the efficient combustion of a hydrocarbon. If there is not enough oxygen available, the combustion is incomplete. Complete combustion of a hydrocarbon produces a blue flame. Incomplete combustion produces a yellow flame. The yellow color is due to the formation of small, glowing carbon particles that are deposited as soot when they cool. Carbon monoxide, a toxic gas, also forms along with carbon dioxide and water during incomplete combustion.

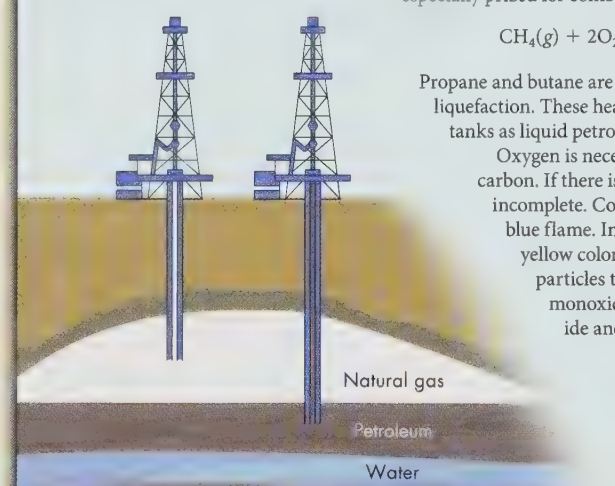


Figure 22.14 Oil and Gas Wells
Wells are drilled to reach natural gas and petroleum deposits.

Focus on ELL

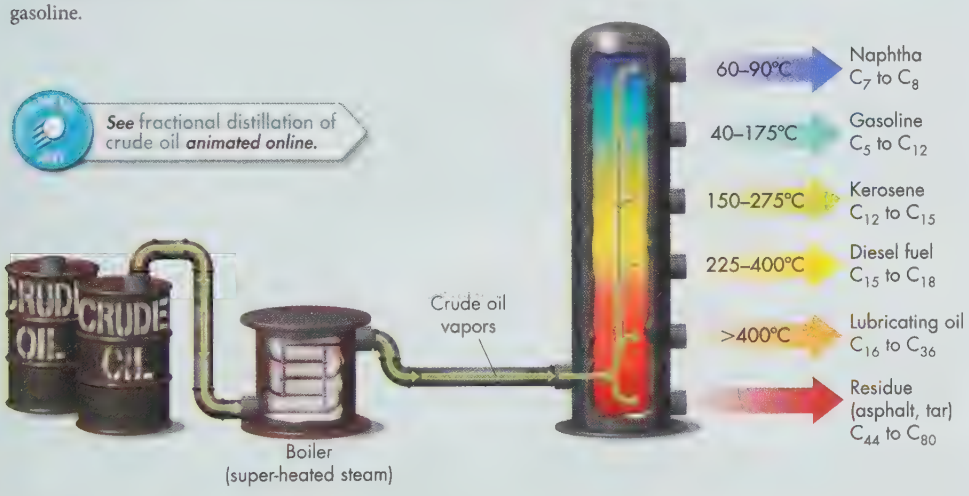
1 CONTENT AND LANGUAGE Have students read the lesson title and each section heading. Have a discussion about what students already know about these subjects. Record their statements in a KWL chart. Provide students with a copy of the chart to complete as you proceed with the lesson.

2 FRONTLOAD THE LESSON Review the carbon cycle with students. Ask students to identify the processes of the carbon cycle that are associated with natural gas, petroleum, and coal formation.

3 COMPREHENSIBLE INPUT Use a lit Bunsen burner to demonstrate the difference in flame color between incomplete and complete combustion. Assign the Kinetic Art activity to accompany the discussion on refining petroleum.

Petroleum

What is the first step in the refining of petroleum?



The organic compounds found in petroleum, or crude oil, are more complex than those in natural gas. Most of the hydrocarbons in petroleum are straight-chain and branched-chain alkanes. But petroleum also contains small amounts of aromatic compounds and sulfur-, oxygen-, and nitrogen-containing organic compounds.

Humans have known about petroleum for centuries; ancient peoples found it seeping from the ground in certain areas. In the late 1850s, a vast deposit of petroleum was discovered in Pennsylvania when a well was drilled to obtain petroleum for use as a fuel. Within decades, petroleum deposits had also been found in the Middle East, Europe, and the East Indies. Petroleum has since been found in other parts of the world as well.

Crude oil is a mixture of hydrocarbons having anywhere from 1 carbon atom to more than 40 carbon atoms. Without further treatment, crude oil is not very useful. The mixture must be separated, or refined, into parts called fractions, which have many commercial uses. **Petroleum refining begins with the distillation of crude oil into fractions according to boiling point.** Figure 22.15 shows a schematic of a petroleum refining distillation tower. Each distillation fraction contains several different hydrocarbons.

Note that the gasoline fraction makes up just 40 percent of the crude oil mixture. However, gasoline is by far the most commonly used petroleum product. To make the supply meet the demand, other processes such as cracking are used. **Cracking** is a controlled process by which hydrocarbons are broken down or rearranged into smaller, more useful molecules. For example, fractions containing compounds of higher molar mass are "cracked" to produce the more useful short-chain components of gasoline and kerosene. Hydrocarbons are cracked with the aid of a catalyst and with heat. This process also produces low-molar-mass alkanes, which are used to manufacture paints and plastics. Other catalytic processes besides cracking are used to increase the amounts of components that improve the performance of gasoline.

Figure 22.15 Fractional Distillation of Crude Oil
The crude oil is heated so that it vaporizes and rises through the fractionating column. Compounds with the highest boiling points condense near the bottom. Compounds with the lowest boiling points condense near the top.
Infer *In which fraction would you expect to find decane?*

UbD Check for Understanding

What is the first step in the refining of petroleum?

Ask students to give a one-minute response that describes the difference between distillation and cracking. Answers may be oral or written.

ADJUST INSTRUCTION If students are having difficulty with this exercise, have them reread the last two paragraphs of the Petroleum section and review Figure 22.15. Clarify that cracking is a process that takes place after fractional distillation and is performed to reduce higher molecular mass fractions into more useful short-chain hydrocarbons.

Explain

Petroleum

START A CONVERSATION Explain to the class that it was not until the invention of the kerosene lamp that people valued petroleum. By the time electric lights reduced the need for kerosene, automobiles required gasoline, which previously had been discarded as a useless byproduct of kerosene production. Explain that before the petroleum era began, fats from domesticated animals, whale oil, wood, and coal were used as energy sources.

USE VISUALS Direct students' attention to Figure 22.15. Explain that the crude oil is pumped through the boiler, where it vaporizes. The petroleum vapor enters the fractionating column. The column is divided into chambers with openings in the floor of each chamber to allow the passage of vapors into the chamber. Each chamber is kept at a temperature just below the boiling point of a specific fraction. **Ask** Why do you think the temperature is kept below the boiling point of each fraction? *(The temperature is kept below the boiling point of the given fraction so that those particular vapors will condense back to a liquid, while allowing the other vapors to rise into the next chamber.)*

Extend

Divide the class into five groups. Have each group research a different fraction obtained from crude oil. Challenge each group of students to create a pie graph of the percents of each fraction, highlighting the slice that represents their fraction. The display should also include information on the chemical composition of the fraction and the uses of the products derived from that fraction. Encourage students to illustrate their displays with original art or magazine photographs.

Answers

FIGURE 22.15 Decane has ten carbons, so it should be in the gasoline fraction.

CHEMISTRY & YOU Draw students' attention to the background image and the inset of the remediation worker. Pose the following question to students: *How do the challenges associated with the containment and remediation of an oil spill on the open sea differ from those associated with a land-based spill?* You may need to guide the students in the following ways:

- Computer modeling can be used to predict the spread and movement of ocean spills.
- Shorelines have different uses and characteristics, as well as different sensitivities to oil spills because of the flora and fauna at shorelines.
- Successful bioremediation requires high concentrations of microbes to be in close proximity to the oil.
- Land-based spills pose the risk of contaminants entering the groundwater.

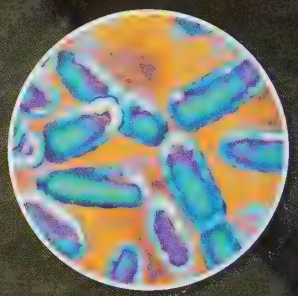
Explain

USE AN ANALOGY Explain that bioremediation is analogous to photosynthesis in plants. Photosynthesis, like bioremediation, uses a process that turns a harmful byproduct of human respiration, carbon dioxide, into oxygen.

Extend

Connect to ENVIRONMENTAL ENGINEERING

Have students research a product that is currently available for bioremediation and write a short paragraph detailing how the product optimizes bacterial consumption of oil.



CHEMISTRY & YOU: TECHNOLOGY

Bioremediation

Oil and water don't mix. You may have witnessed this fact watching footage of an oil spill in the news. Oil spills can lead to the deaths of seabirds and marine mammals and can contaminate soil and drinking water.

One tool being used to clean up spilled oil is a relatively new technology called bioremediation. The technology uses "oil-eating" microbes—particularly bacteria—to remedy the spill. For these microbes, the hydrocarbons in crude oil are not a contaminant but a food source. During the digestion process, harmful hydrocarbons are converted to less harmful products—mainly carbon dioxide and water. Bioremediation is a safe, simple, and relatively inexpensive method of dealing with spilled oil. However, the process takes time to work. In addition, it is usually only effective on residual oil on shorelines, after part of the spill has been removed by other means.

HIGH-TECH . . . AND ALIVE The degradation of petroleum in the marine environment is carried out by diverse microorganisms, including the *Pseudomonas* species shown here.

Take It Further

1. Describe Two hydrocarbons found in crude oil spills are methylbenzene and methylcyclopentane. Draw structural formulas for these two compounds.

2. Research a Problem Another technology called a dispersion agent is often used to remedy oil spills. Research this technology and compare it to bioremediation.

21st Century Learning To be successful in the 21st century, students need skills and learning experiences that extend beyond subject matter mastery. The following project helps students build the following 21st Century Skills: *Financial, Economic, Business, and Entrepreneurial Literacy*; *Creativity and Innovation*; *Communication and Collaboration*; *Information, Media, and Technology Literacy*; *Initiative and Self-Direction*; and *Productivity and Accountability*.

CALL TO ACTION Tell students that a prominent wildlife protection society is concerned about the ongoing environmental problems at the site of an old oil spill. The society has need of an Internet-savvy public relations agency to create an awareness campaign about the site. Pose the following challenge to students: *Form an "agency" of four to six students to create a Web site designed to showcase the history of the spill and its environmental impact, remediation progress, and cumulative costs.* Base the campaign on an actual oil spill that affected a marine ecosystem, an estuary/wetland ecosystem, or a human community. Include an appeal to the public to support safer, improved oil transportation/storage methods and remediation technologies.

Coal

What characteristics are used to classify coal?

Geologists think that coal had its origin some 300 million years ago when huge tree ferns and mosses grew abundantly in swampy tropical regions. When the plants died, they formed thick layers of decaying vegetation. Layer after layer of soil and rock eventually covered the decaying vegetation, which caused a buildup of intense pressure. This pressure, together with heat from Earth's interior, slowly turned the plant remains into coal.

CHEMISTRY & YOU

Q: *Where does gasoline come from? Where does coal come from? Use Figures 22.14, 22.15, and 22.16 to explain your answers.*

Coal Formation The first stage in the formation of coal is an intermediate material known as peat. Peat, shown in Figure 22.16, is a soft, brown, spongy, fibrous material. When first dug out of a bog, peat has a very high water content. After it has been allowed to dry, it produces a low-cost but smoky fuel. If peat is left in the ground, it continues to change. After a long period of time, peat loses most of its fibrous texture and becomes lignite, or brown coal. **Coal is classified by its hardness and carbon content.** For example, lignite is much harder than peat and has a higher carbon content (about 30 percent). The water content, however, is still high. Continued pressure and heat slowly change lignite into bituminous coal, or soft coal, which is harder than lignite. Bituminous coal has a lower water content and higher carbon content (35 percent to 85 percent) than lignite. In some regions of Earth's crust, even greater pressures have been exerted. In those places, such as the earth beneath eastern Pennsylvania, soft coal has been changed into anthracite, or hard coal. Anthracite has a carbon content that exceeds 85 percent, making it an excellent fuel source.

Coal, which is usually found in seams from 1 to 3 meters thick, is obtained from both underground and surface mines. In North America, coal mines are usually less than 100 meters underground. Much of the coal is so close to the surface that it is strip mined. By contrast, many coal mines in Europe and Asia extend 1000 to 1500 meters below Earth's surface.

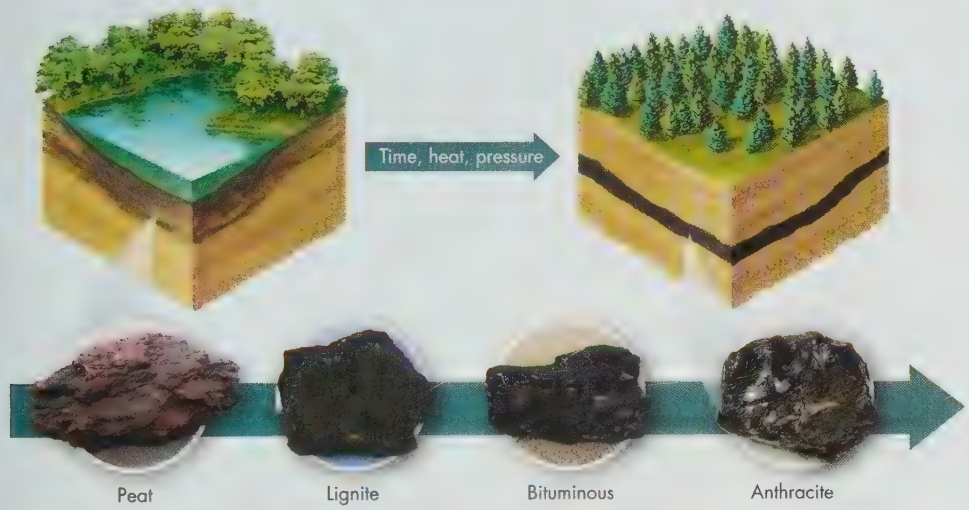


Figure 22.16 Coal Formation When tree ferns and mosses die, their decomposing remains build up. Over millions of years, layers of decaying organic material pile up and form peat. Continued pressure and heat transform peat into lignite, bituminous coal, and anthracite coal.
Identify *What three variables contribute to coal formation?*

Differentiated Instruction

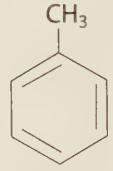
LPR LESS PROFICIENT READERS Present the information about coal formation, coal composition, and coal production in a bulleted summary list. Have students use the list to create a flowchart.

ELL ENGLISH LANGUAGE LEARNERS Relate water wells to oil and gas wells. Use pictures and diagrams to demonstrate the similarities and differences between water wells, oil wells, and natural gas wells.

L3 ADVANCED STUDENTS Have students research the energy sources used in the United States. Have them summarize their findings in a bar chart showing to what extent the United States depends on each type of energy source. The bar chart should profile the energy sources for the years 1850, 1900, 1950, 1990, 2000, and 2010.

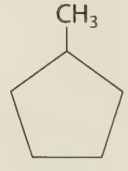
Explain

Coal



USE A DIAGRAM Have students study Figure 22.16 and read the caption. If possible, show the students actual samples of peat, lignite, bituminous coal, and anthracite coal. Explain that coal can be converted to methane by a process called coal gasification, in which coal and hydrogen react under high temperature and pressure. Synthetic crude oil can be made by a process called coal liquefaction, in which coal is dissolved in a solvent at high pressure and temperature. Point out that the product, called solvent-refined coal, is then purified and heated. The hard, brittle residue that remains can be melted and used as a liquid fuel.

CRITICAL THINKING Both coal gasification and coal liquefaction produce products that burn more cleanly and efficiently than coal and can be used in place of coal and petroleum products to power steam generators in electrical power plants. Make sure students understand that, like conventional coal and petroleum products, the products of coal gasification and liquefaction produce greenhouse gases when combusted. However, the carbon dioxide produced while burning the coal gas can more easily be captured, or *sequestered*, before it escapes into the atmosphere. Challenge students to explain how the use of coal-based products in place of coal or petroleum might benefit both humans and the environment. *(fewer emissions due to burning more cleanly than unprocessed coal; lower cost to electrical customers due to increased efficiency; less carbon dioxide entering the atmosphere if sequestered; potential for less dependence on foreign oil resources)*



Answers

TAKE IT FURTHER

1.

Methylbenzene

Methylcyclopentane

2. The goal when using a dispersion agent is simply to mix the oil with the water, whereas bioremediation aims to rid the water of the harmful hydrocarbons of the oil spill.

FIGURE 22.16 time, heat, and pressure

Extend

Scientists have tried for years to determine whether hydrocarbons could have been created deep in the Earth and formed without organic matter. Have students research this issue and report back the current status of findings. *(As of July 2009, scientists have found that ethane and heavier hydrocarbons can be formed under the pressure-temperature conditions of the upper mantle of the Earth.)*

Evaluate

Informal Assessment

Have students create a three-column chart to compare and contrast the formation and composition of coal, natural gas, and petroleum. *(Petroleum and natural gas are formed from marine organisms buried under ocean sediments; coal is formed from buried wetland plants. Natural gas and petroleum contain mostly aliphatic compounds; coal contains a large percentage of aromatic compounds.)* Then have students complete the 22.5 Lesson Check.

Reteach

Display Figure 22.15 on an overhead projector. If possible, bring a sample of crude oil to class so that students can observe its color and odor. Explain that petroleum is a complex mixture of hydrocarbons whose molecules range in size from 1 to more than 40 carbon atoms. To be used effectively, the crude oil must be refined by fractional distillation, which separates compounds on the basis of their boiling points. Explain that in general, low molar mass compounds have low boiling points and high molar mass compounds have high boiling points.

Composition of Coal Coal consists largely of condensed aromatic compounds of extremely high molar mass. These compounds have a high proportion of carbon compared with hydrogen. Due to the high proportion of aromatic compounds, coal leaves more soot when burned than the more aliphatic fuels obtained from petroleum. Coal also contains a small amount of sulfur. As coal burns, the sulfur oxidizes to form SO_2 and SO_3, two major air pollutants that contribute to acid rain and the smog shown in Figure 22.17. In order to reduce air pollution, the majority of sulfur is removed before the coal is burned. Any sulfur oxides present after combustion are generally captured before the emissions leave the smokestack.

Coal may be distilled to obtain a variety of products: coal gas, coal tar, ammonia, and coke. Coke is the solid material left after coal distillation. It is used as a fuel in many industrial processes and is the crucial reducing agent in the smelting of iron ore. Coal gas consists mainly of hydrogen, methane, and carbon monoxide. Coal tar can be distilled further into benzene, toluene, naphthalene, phenol, and pitch. The ammonia from distilled coal is converted to ammonium sulfate for use as a fertilizer.

Figure 22.17 Smog in Beijing Sulfur oxides from emissions of coal-fired plants in China often contribute to dense smog.

22.5 LessonCheck

33. Describe Which type of hydrocarbons can be found in natural gas?

34. Review Describe the first process used in the refining of petroleum.

35. Identify What are the two characteristics used to classify coal?

36. Compare How do the combustion products differ for complete and incomplete combustion of hydrocarbons?

37. Explain Why is cracking a necessary step in the petroleum refining process?

38. List What are some common products made from natural gas, petroleum, and coal?

39. Summarize How did each of the three major fossil fuels form?

40. Compare How do the chemical compositions of natural gas, petroleum, and coal differ?

Lesson Check Answers

33. alkanes of low molar mass

34. The refining process starts with the distillation of petroleum into fractions according to boiling point.

35. hardness and carbon content

36. For complete combustion, the products are carbon dioxide and water. For incomplete combustion, carbon monoxide and soot form in addition to carbon dioxide and water.

37. Amounts of products obtained by fractional distillation don't match demands. Cracking breaks down hydrocarbons into smaller, more useful components.

38. sample answers: petroleum: paints and plastics; coal: ammonia fertilizer

39. Heat, pressure, and bacteria changed marine organisms buried in ocean sediments into petroleum and natural gas. Heat and pressure changed buried layers of vegetation into coal.

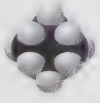
40. Natural gas largely consists of lighter alkanes such as methane, ethane, propane, and butane. Coal consists largely of aromatic compounds of extremely high molar mass. Petroleum consists largely of hydrocarbons that fall between those of natural gas and coal.

Small-Scale Lab

Hydrocarbon Isomers

Purpose

To draw line-angle formulas and name some of the isomers in gasoline



Materials

- toothpicks
- modeling clay
- pencil
- paper

Procedure

Gasoline is a complex mixture of hydrocarbon molecules. Generally, each molecule contains between five and twelve carbon atoms. Many of the components of gasoline are isomers with the same molecular formula. These components include the isomers of pentane. Study the formulas and names of the constitutional isomers of C_5H_{12} in the table below. Make a model of each isomer using toothpicks and modeling clay, using the space-filling models as a guide. Compare the models for each isomer.

Isomers of C_5H_{12}

Condensed formula	Line-angle formula	Space-filling model
$CH_3CH_2CH_2CH_2CH_3$ pentane		
$CH_3CHCH_2CH_3$ (with CH_3 branch) 2-methylbutane		
$CH_3C(CH_3)_2CH_3$ 2,2-dimethylpropane		

Analyze and Conclude

1. Describe Draw the complete structural formula for each isomer of C_5H_{12} in the table.

2. Infer In a line-angle formula, each line represents a carbon-carbon bond. Each end of a line, as well as the intersection of lines, represents a carbon atom. Knowing that carbon always forms four covalent bonds, explain how to determine the number of hydrogen atoms bonded to each carbon in a line-angle formula.

3. Describe Because butane can vaporize readily, it is used in the formulations of gasolines in cold climates during winter. Draw condensed structural formulas and line-angle formulas for the two isomers of butane (C_4H_{10}).

You're the Chemist

1. Analyze Data Gasoline contains isomers of hexane, too. Draw the line-angle formulas and name the five isomers of C_6H_{14}. Make a model of each isomer.

2. Design an Experiment Gasoline also contains small amounts of the six isomers of pentene. Two of the isomers are *cis* and *trans* configurations of the same constitutional isomer. Experiment with your models to make the six isomers. Use two toothpicks to represent a double bond. Draw line-angle formulas for each isomer. Name each compound.

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the lab. Make sure each group has ELLs of varied language proficiencies so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

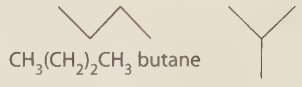
BEGINNING: LOW/HIGH Use the table of isomers to explain the purpose and the procedure of the lab. Assist students in creating their clay models. Encourage students to make a sketch of what they want each model to look like.

INTERMEDIATE: LOW/HIGH Paraphrase the procedure for students. Read out loud the Analyze and Conclude questions.

ADVANCED: LOW/HIGH Have students develop their own questions that could be answered by another student working on the same lab.

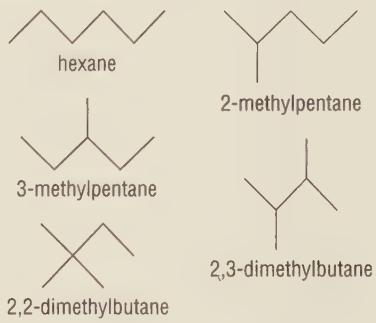
Explore

Small-Scale Lab

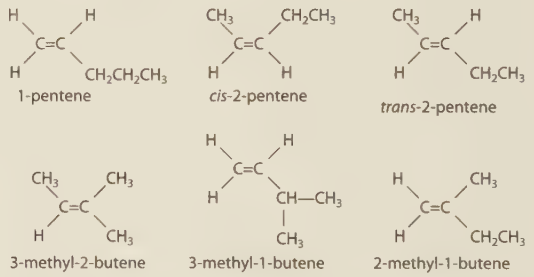


OBJECTIVE After completing this activity, students will be able to write line-angle formulas for hydrocarbons.

SKILLS FOCUS analyze



PREP TIME 5 minutes



CLASS TIME 20 minutes

ANALYZE AND CONCLUDE

1. Students should draw formulas for pentane, 2-methylbutane, and 2,2-dimethylpropane.
2. Subtract from 4 the number of lines drawn to any point.

22 Study Guide

BIG IDEA CARBON CHEMISTRY

Hydrocarbons are named using the IUPAC system, although sometimes common names are used for certain familiar compounds. All hydrocarbons are nonpolar molecules. In general, the fewer carbon atoms in a hydrocarbon, the lower its melting and boiling points. Hydrocarbons with the same molecular formula but different molecular structures can have different properties.

22.1 Hydrocarbons

- Because carbon has four valence electrons, a carbon atom always forms four covalent bonds.
- The carbon atoms in an alkane can be arranged in a straight chain or in a chain that has branches.

- hydrocarbon (762)
- alkane (764)
- straight-chain alkane (764)
- homologous series (765)
- condensed structural formula (766)
- substituent (767)
- alkyl group (768)
- branched-chain alkane (768)

22.2 Unsaturated Hydrocarbons

- At least one carbon-carbon bond in an alkene is a double covalent bond. Other bonds may be single carbon-carbon bonds and carbon-hydrogen bonds.
- At least one carbon-carbon bond in an alkyne is a triple covalent bond. Other bonds may be single or double carbon-carbon bonds and carbon-hydrogen bonds.

- saturated compound (772)
- unsaturated compound (772)
- alkene (772)
- alkyne (773)

22.3 Isomers

- Constitutional isomers differ in physical properties such as boiling point and melting point. They also have different chemical reactivities.
- Two types of stereoisomers are *cis-trans* isomers and enantiomers.

- isomer (775)
- constitutional isomer (775)
- stereoisomer (776)
- *cis-trans* isomer (776)
- *cis* configuration (776)
- *trans* configuration (776)
- asymmetric carbon (776)
- enantiomer (777)

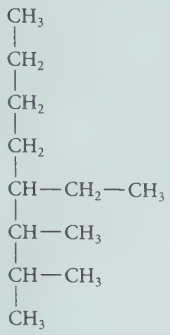
22.4 Hydrocarbon Rings

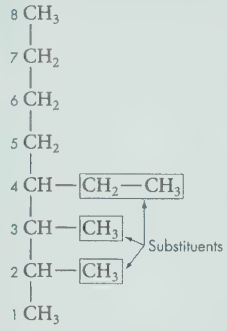
- In some hydrocarbon compounds, the carbon chain is in the form of a ring.
- In a benzene molecule, the bonding electrons between carbon atoms are shared evenly around the ring.

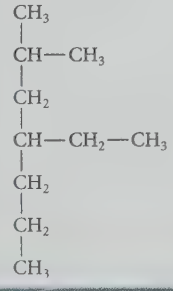
- cyclic hydrocarbon (779)
- cycloalkane (779)
- aromatic compound (780)
- aliphatic compound (780)

22.5 Hydrocarbons From Earth's Crust

- Natural gas is an important source of alkanes of low molar mass.
- Petroleum refining begins with the distillation of crude oil into fractions according to boiling point.
- Coal is classified by its hardness and carbon content.







- cracking (783)

UbD Performance Tasks

ROLE REVERSAL Swap roles with the students, and have them create a computerized presentation and give a lecture on naming hydrocarbons. Presentations should include visual representations as well as step-by-step procedures. Explain that the lecture should include various examples, give tips to avoid common mistakes, and conclude with a brief set of practice problems.

SAY IT WITH GRAPHS Have students create large, colorful graphs of the first ten alkanes to convey the ratio of composition of carbon/hydrogen by percent weight. Students should arrange their graphs so that any pattern they notice between the carbon atoms and the percentage of carbon in the alkanes is obvious. Ask students to include an overall statement summarizing their findings.

Skills Tune-Up: Structural Formulas

Problem	❶ Analyze	❷ Solve
Name this compound using the IUPAC system. 	• The carbons on the parent hydrocarbon should be numbered to give the substituents the lowest possible numbers. • The location numbers for the substituents are included in the prefix. If there are multiple substituents of the same type, include that information in the prefix as well, for example, *di-* or *tri-* for two or three substituents, respectively. • The names of the substituents should be listed in alphabetical order with correct punctuation. Hint: Review Sample Problem 22.2 if you have trouble naming branched-chain alkanes.	Parent hydrocarbon: eight carbon atoms (octane) Substituents and their locations: • methyl group on carbon 2 • methyl group on carbon 3 • ethyl group on carbon 4  Prefix: 4-ethyl-2,3-dimethyl The IUPAC name is 4-ethyl-2,3-dimethyloctane.
Draw a condensed structural formula for 4-ethyl-2-methylheptane. Hint: Review Sample Problem 22.3 if you have trouble drawing structural formulas for branched-chain alkanes.	• The part of the name that ends in *-ane* identifies the parent hydrocarbon. • Prefixes identify the substituents, how many times they appear, and the location of each on the parent hydrocarbon. • Each carbon atom must have four covalent bonds. Hydrogens should be added to meet this need.	Parent hydrocarbon: heptane (seven carbon atoms) Substituents and their locations: • ethyl group on carbon 4 • methyl group on carbon 2 The structural formula for 4-ethyl-2-methylheptane is 

Focus on ELL

5 ASSESS UNDERSTANDING Assess students' understanding by using a portfolio for this chapter. Include various types of learning assignments, based on each student's language proficiency.

BEGINNING

LOW Include models or pictures of models created by the student.

HIGH Include copies of the graphic organizers used to take notes or any double-bubble diagrams that show similarities and differences between the different types of hydrocarbons.

INTERMEDIATE

LOW Include any prereading predictions made about lesson topics, as well as the results of those predictions.

HIGH Include any lab write-ups that were assigned during the chapter.

ADVANCED: LOW/HIGH Include an essay that asks the student to compare and contrast different types of hydrocarbons.

Skills Review

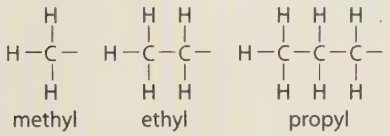
Example and sample practice problems for the various hydrocarbon problems can be found on the following pages:

LESSON 22.1 Drawing Structural Formulas for Alkanes—page 767; Naming Branched-Chain Alkanes—page 770; Drawing Structural Formulas for Branched-Chain Alkanes—page 771

LESSON 22.3 Identifying Asymmetric Carbon Atoms—page 777

ASSESSMENT

Answers



LESSON 22.1

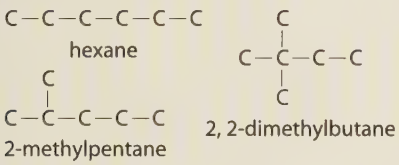
41. The carbon-carbon bonds are nonpolar and the carbon-hydrogen bonds are very weakly polar.

42. pentane: $CH_3CH_2CH_2CH_2CH_3$
hexane: $CH_3CH_2CH_2CH_2CH_2CH_3$

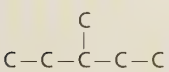
43. **a.** propane
b. octane
c. pentane

44.

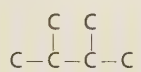
45. **a.** 2-methylbutane
b. 2,3-dimethylbutane
c. 3-methylhexane



LESSON 22.2



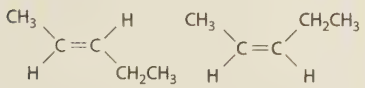
46. **a.** propene
b. *trans*-2-pentene
c. 4-methyl-1-pentene
d. 3-ethyl-2-methyl-2-pentene

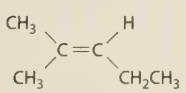


47. **a.** unsaturated, because there is a double carbon-carbon bond
b. saturated, because the compound contains the maximum number of hydrogen atoms per carbon atom

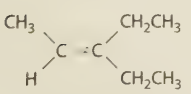
LESSON 22.3

48.





49. **a.** Accept any isomer with 5 carbons and 12 hydrogens.
b. Accept any isomer with 7 carbons and 16 hydrogens.



50. **a.**

b.

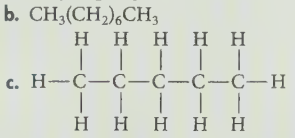
c.

51. No, hexane contains no substituted groups.

52. No, only molecules with at least one asymmetric carbon can have enantiomers.

22 Assessment

* Solutions appear in Appendix E



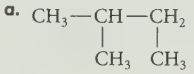
Lesson by Lesson

22.1 Hydrocarbons

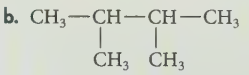
41. Why are alkane molecules nonpolar?

***42.** Draw condensed structural formulas for pentane and hexane. Assume that the C—H and C—C bonds are understood.

43. Name the alkanes that have the following molecular or structural formulas.
a. $CH_3CH_2CH_3$
b. $CH_3(CH_2)_6CH_3$

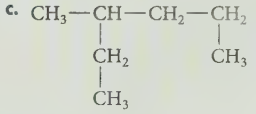


c.



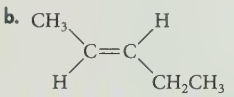
44. Draw structures for the alkyl groups derived from methane, ethane, and propane.

***45.** Give the IUPAC name for each compound.

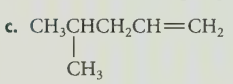


a.

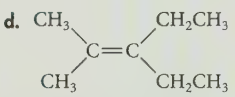
b.



c.



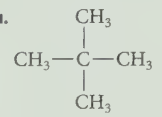
22.2 Unsaturated Hydrocarbons



46. Give the IUPAC name for these alkenes.
a. $CH_3CH=CH_2$
b.

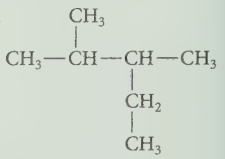
c.

d.



***47.** Classify each of the following compounds as saturated or unsaturated. Explain.
a. $CH_3CH=CHCH_2CH_3$
b. $CH_3CH_2CH_3$

22.3 Isomers



48. Draw and name all the constitutional isomers with the molecular formula C_6H_{14}.

49. Draw one constitutional isomer of each compound.

a.

b.

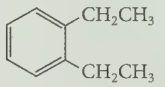
50. Draw a structural formula or carbon skeleton for each of the following alkenes. If *cis* and *trans* forms are present, include both forms.
a. 2-pentene
b. 2-methyl-2-pentene
c. 3-ethyl-2-pentene

51. Can you draw a constitutional isomer of hexane that has an asymmetric carbon? Explain.

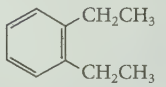
***52.** Do all molecules have enantiomers? Explain.

22.4 Hydrocarbon Rings

53. Give the IUPAC name for the following cyclic hydrocarbons.

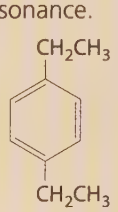


a.



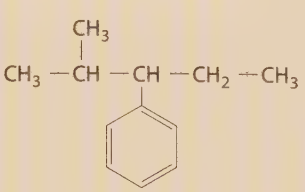
b.

54. Explain why both of these structures represent 1,2-diethylbenzene.



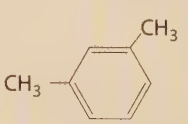
***55.** Draw a structural formula for each compound.
a. 1,4-diethylbenzene
b. 2-methyl-3-phenylpentane
c. 1,3-dimethylbenzene

LESSON 22.4



53. **a.** cyclooctane
b. cyclobutane

54. Two different structural formulas are possible because a benzene ring exhibits resonance.



55. **a.**

b.

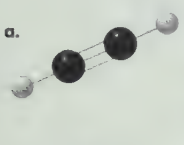
c.

22.5 Hydrocarbons From Earth's Crust

56. Rank these materials in order of increasing carbon content: bituminous coal, peat, lignite, and anthracite coal.

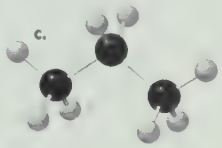
57. How are catalysts used in petroleum refining?

***58.** What happens to the sulfur when coal burns?



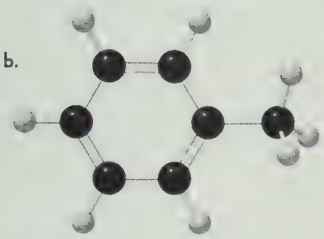
Understand Concepts

59. Why are the following names incorrect? What are the correct names?



a. 2-dimethylpentane
b. 1,3-dimethylpropane
c. 3-methylbutane
d. 3,4-dimethylbutane

***60.** For each hydrocarbon shown, identify the type of covalent bonds and name the compound.



a.

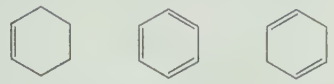
c.

b.

61. Write structural formulas for these compounds.

a. propyne
b. cyclohexane
c. 2-phenylpropane
d. 2,2,4-trimethylpentane

***62.** After ethane, what are the next three members of the homologous series of alkanes?



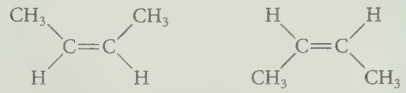
63. Compare *cis-trans* isomers and enantiomers.

64. Draw electron dot structures for each compound.

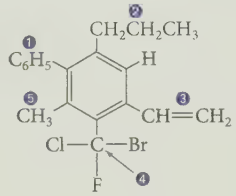
a. propene
b. propane
c. propyne
d. cyclobutane

65. Write an equation for the combustion of octane.

***66.** Compare these three molecular structures. Which would you expect to be most stable? Explain your answer.



67. The four hydrocarbons produced in the largest amounts in the United States in a recent year are listed in the table below. Answer the following questions based on the data given.



Chemical	Amount produced (billions of kg)
Ethene	15.9
Propene	8.4
Benzene	5.3
Ethylbenzene	4.3

a. How many billion kilograms of aromatic compounds were produced?
b. Of the total mass of all four compounds produced, what percent by mass was made up of aliphatic compounds?

***68.** Are these two structures *cis-trans* isomers? Explain your answer.

69. Use the labeled features in the molecular structure below to answer the following questions.

a. Which label identifies a double bond?
b. Which label identifies a phenyl group?
c. Which label identifies a methyl group?
d. Which label identifies an asymmetric carbon?
e. Which label identifies a propyl group?

70. Does ethylcyclohexane have an asymmetric carbon? Explain.

67. **a.** 9.6 billion kg
b. 72%

68. No, the structures are identical; one has been flipped over.

69. **a.** 3 **b.** 1
c. 5 **d.** 4
e. 2

70. No, two of the R groups (those forming the ring) are identical.

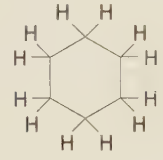
ASSESSMENT

LESSON 22.5

56. peat, lignite, bituminous coal, anthracite coal

57. During cracking, catalysts are used to produce more short-chain components.

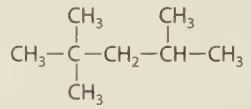
58. The combustion of sulfur in coal produces the air pollutants SO_2 and SO_3.



UNDERSTAND CONCEPTS

59. **a.** The *di-* indicates two methyl groups, but only one location is given; 2,2-dimethylpentane.
b. Alkyl groups on end carbons are part of the chain; pentane.
c. The chain wasn't numbered so the substituent has the lowest possible number; 2-methylbutane.
d. The methyl group on carbon 4 is part of the chain; 3-methylpentane

60. **a.** Ethyne (acetylene) has one triple carbon-carbon bond and two single carbon-hydrogen bonds.
b. In methylbenzene, there are hybrid bonds within the ring. All other bonds are single bonds.
c. All the bonds in propane are single bonds.

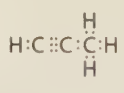


61. **a.** $CH \equiv C-CH_3$

b.

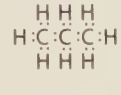
c. $CH_3-CH(-CH_3)-C_6H_5$

d.

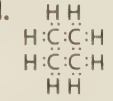


62. propane, butane, pentane

63. *Cis-trans* isomers and enantiomers are both types of stereoisomers. *Cis-trans* isomers differ in the arrangement of substituent groups attached to each carbon in a double bond. In enantiomers, there is at least one asymmetric carbon.



64. **a.**



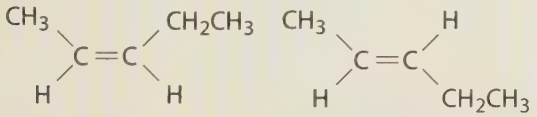
c.

b.

d.

65. $2C_8H_{18}(l) + 25O_2(g) \rightarrow 16CO_2(g) + 18H_2O(l)$

66. The middle structure is most stable due to resonance within the ring.



71. **a.** 4
b. 2
c. 3
d. 1

THINK CRITICALLY

72. The amount of heat per carbon is higher for methane (–890 kJ/mol of carbon burned) than for benzene (–545 kJ/mol of carbon burned). Burning aromatic compounds produces more soot.

73. *Meth-* implies one carbon atom; *ene-* implies a double bond, which requires two carbon atoms.

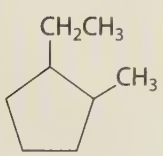
74. The methyl and ethyl groups can be on the same side of the bond or opposite sides.

trans-2-pentene *cis*-2-pentene

75. Students may infer that the ring structures in cyclic hydrocarbons produce stronger van der Waals attractions, which increase the energy required for vaporization.

76. $CH_2=C=CH_2$

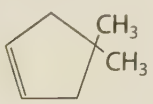
77. The cycloalkene would be least stable because the bond angles are 90° instead of the 120° predicted by VSEPR theory.



(cycloalkene)

CH_2=CHCH=CH_2 (alkadiene)

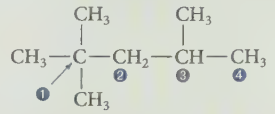
78. **a.** $CH_3CH_2C=CCH_2CH_3$ (with CH_3 CH_3)



b.

c. $CH_2CH_2CH_3$ / $CH_3(CH_2)_3C(CH_2)_4CH_3$ / $CH_2CH_2CH_3$

79. Alkanes contain only single bonds. Alkenes contain at least one double bond. Aromatic hydrocarbons contain a benzene ring or a similar ring. Cycloalkanes contain aliphatic chains that are arranged in a ring.



80. **b.**

c. $CH_3-C\equiv C-CH_2-CH_3$
d. $CH_2=CH-CH_2-CH_3$

81. The alkane is ethane.
$2CH_3CH_3 + 7O_2 \rightarrow 4CO_2 + 6H_2O$

***71.** Use the labeled features in the molecular structure below to answer the following questions.

a. Which label identifies a primary carbon?
b. Which label identifies a secondary carbon?
c. Which label identifies a tertiary carbon?
d. Which label identifies a quaternary carbon?

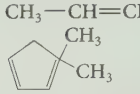
Think Critically

***72.** **Infer** Methane (CH_4), a widely used fuel, has a heat of combustion (ΔH) of −890 kJ/mol. The ΔH for benzene (C_6H_6) is much higher, −3268 kJ/mol, yet benzene alone is never used as a fuel. Suggest some reasons why benzene is a less desirable fuel than methane.

73. **Analyze** Explain why you cannot draw a structural formula for methene.

74. **Use Models** Use the isomers of 2-pentene to show how lack of rotation about a carbon-carbon double bond leads to *cis-trans* isomers.

75. **Infer** Most cyclic hydrocarbons have higher boiling points than alkanes with the same number of carbons. Suggest a possible explanation for this general difference in boiling points.



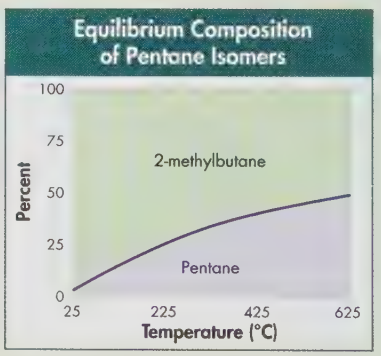
***76.** **Apply Concepts** Alkadienes are hydrocarbons with two double bonds. Draw the structural formula of the alkadiene with the molecular formula C_3H_4.

77. **Predict** The molecular formula C_4H_6 could represent an alkyne, a cycloalkene, or a hydrocarbon with two double bonds. Write a condensed structural formula for each. Which compound do you think is the least stable? Why?

***78.** **Apply Concepts** Draw structural formulas for the following compounds:
a. 3,4-dimethyl-3-hexene
b. 1-ethyl-2-methylcyclopentane
c. 5,5-dipropyldecane

79. **Compare** What structural feature is associated with each of these hydrocarbons: an alkane, an alkene, an aromatic hydrocarbon, and a cycloalkane?

80. **Evaluate and Revise** Draw a correct structure for any of the choices below that are incorrect.
a. $CH_3-CH=CH-CH_2-CH_3$
b.



c. $CH_3-C\equiv CH-CH_2-CH_3$
d. $CH_3=CH-CH_2-CH_3$

81. **Apply Concepts** Upon complete combustion, a gaseous alkane gives a volume of carbon dioxide that is twice the volume of the starting alkane at the same temperature and pressure. Identify the alkane and write the balanced equation for its combustion.

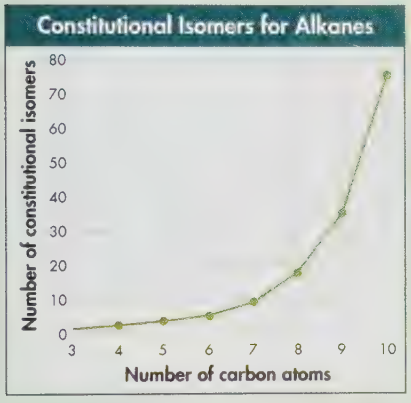
***82.** **Apply Concepts** The alkanes 2-methylbutane and pentane are readily interconverted, or isomerized, in the presence of a catalyst.
a. Write a balanced chemical equation for this isomerization reaction.
b. What kind of isomers are 2-methylbutane and pentane?
c. Which isomer most likely has the lowest boiling point?

83. **Interpret Graphs** The graph shows the relationship between temperature and the composition of equilibrium mixtures of 2-methylbutane and pentane in the presence of a catalyst.
a. The equilibrium mixtures contain the most of which isomer?
b. Could you obtain better yields of the isomer 2-methylbutane by running the reaction at higher or lower temperatures?
c. At what temperature could you run the reaction to obtain a mixture that contains about 25 percent pentane and 75 percent 2-methylbutane?

82. **a.** $CH_3CH_2CH_2CH_2CH_3 \rightleftharpoons CH_3CHCH_2CH_3$ (CH_3 on the second carbon)
b. constitutional isomers
c. 2-methylbutane

83. **a.** 2-methylbutane
b. lower temperatures
c. about 225°C

Enrichment



84. Predict Use the graph in Figure 22.3 to predict the boiling point of dodecane, the straight-chain alkane containing twelve carbons. Then use a chemistry handbook to find the actual boiling point of dodecane. Compare the actual boiling point with your prediction.

85. Apply Concepts Correct each of the following names and draw the correct structural formulas.

a. 4-methylhexane
b. 1,4-diethyl cyclopentane
c. 3,3methyl-4-ethyloctane
d. 4,4-dimethylpentane
e. 2-ethylheptane
f. phenylmethane

***86. Interpret Graphs** The graph shows the number of constitutional isomers for alkanes with three to ten carbon atoms.

a. How many constitutional isomers are there for the C_6, C_7, C_8, C_9, and C_{10} alkanes?
b. The difference between the number of isomers for C_7 and C_8 is 9. The difference between the number of isomers for C_9 and C_{10} is 40. In each case, one additional carbon atom is added to the molecule. Why is the change in the number of isomers so different?

87. Evaluate Fossil fuels such as oil and natural gas are the raw materials for many consumer products. Should this information affect the decision to develop energy sources other than fossil fuels? Explain.

Write About Science

88. Research a Problem When fossil fuels burn in an internal combustion engine, the exhaust contains more than carbon dioxide gas and water vapor. Research how catalytic converters work, and write a paragraph explaining what happens to pollutants in a catalytic converter.

89. Connect to the BIGIDEA You've probably seen the instruction "Shake well before using" on a salad dressing bottle. These instructions usually appear on dressings that contain olive oil and water as two of the main ingredients. The molecules in olive oil have long hydrocarbon tails. Explain why you need to shake these types of salad dressings before pouring them onto your salad.

CHEMYSTERY

Nose for Hire

After finishing up with the smell test, Anthony immediately went home and jumped on the Internet to research limonene. He discovered that the two limonene compounds were enantiomers. The right-handed enantiomer smells like oranges, and the left-handed one smells like pine trees. He read on to learn that a nose, like all human tissue, is composed of molecules with asymmetric carbons. As a result, the molecules in your nose that are responsible for detecting smell react differently to the two enantiomers of limonene.

This phenomenon is common in compounds with asymmetric carbons. Another example is the two enantiomers of the compound carvone. One enantiomer smells like spearmint and the other enantiomer smells like the spice caraway.

***90. Infer** Do physical properties such as color, density, and boiling point differ for the two enantiomers of limonene?

91. Connect to the BIGIDEA Many medications have asymmetric carbons. There are cases in which one enantiomer helps, while the other causes severe harm. How is this occurrence possible?

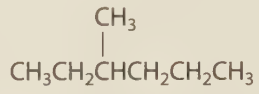
CHEMYSTERY

MAKE A CONNECTION Direct students to read the CHEMystery. Explain that humans have an area in the back of their nasal cavities that is layered with chemically sensitive nerve cells. These nerve cells react with the emitted molecules and send a signal off to the brain, triggering the involuntary smell response.

Since humans are not alike, it makes sense that each person's response to a smell is not always the same as other people's responses. Guide interested students to research the work of British scientist John Amoore, his conclusions about people's perception of smell, and a condition called anosmia. Amoore's findings account for why some people have a stronger sense of smell than other people have.

CHEMYSTERY ANSWERS

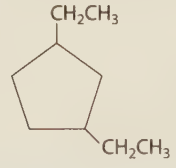
90. No, enantiomers have identical physical properties.



91. BIGIDEA Medications must often interact with a particular protein, which also has asymmetric carbons. Sometimes, one enantiomer of the medication is metabolized differently or interacts with a completely different protein, causing adverse effects.

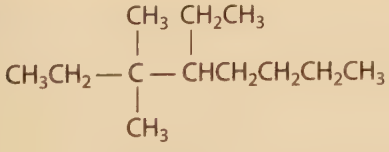
Answers

ENRICHMENT



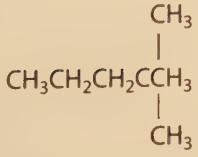
84. The estimated boiling point should be greater than 200°C. The actual boiling point is 216°C.

85. a.



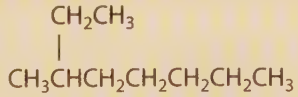
3-methylhexane

b.



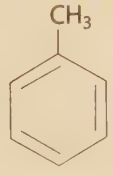
1,3-diethylcyclopentane

c.



3,3-dimethyl-4-ethyloctane

d.



2,2-dimethylpentane

e.

3-methyloctane

f.

Methylbenzene

86. a. $C_6 = 5$, $C_7 = 9$, $C_8 = 18$, $C_9 = 35$, $C_{10} = 75$

b. As the size of the alkane molecule gets larger, the number of different ways that the carbon atoms can be bonded together (to form constitutional isomers) increases dramatically.

87. Answers will vary, but should reflect that fossil fuels are not renewable.

WRITE ABOUT SCIENCE

88. Answers will vary.

89. The long hydrocarbon tails on the molecules in olive oil are nonpolar and do not mix with the polar water molecules. The two phases are completely separated before shaking.

CUMULATIVE REVIEW

92. **a.** 13.9 L
b. 1 L
c. 20 kPa

93. 1.13 mol KNO_3; 114 g KNO_3

94. 3.04×10^2 calories

95. 1.67×10^2 J

96. 1 cal = 4.184 J; 1 kcal = 4.184×10^3 J

97. **a.** Decreasing particle size speeds up the reaction.
b. Increasing the temperature usually speeds up the reaction.

98. **a.** favors reactants **b.** favors products

99. **a.** $K_{eq} = \dfrac{[ICl]^2}{[I_2][Cl_2]}$

b. $K_{eq} = \dfrac{[H_2][Br_2]}{[HBr]^2}$

c. $K_{eq} = \dfrac{[HCl]^4[S]^3[SO_2]}{[S_2Cl_2]^2[H_2O]^2}$

d. $K_{eq} = \dfrac{[NH_3]^2}{[N_2][H_2]^2}$

100. **a.** 10.00 **b.** 7.59
c. 12.00 **d.** 11.70

101. **a.** ~8 **b.** Use a pH meter.

102. **a.** H_3PO_4 **b.** CsOH **c.** H_2CO_3 **d.** $Be(OH)_2$

103. **a.** $NaOH(aq) \rightarrow Na^+(aq) + OH^-(aq)$
b. $Ba(OH)_2(aq) \rightarrow Ba^{2+}(aq) + 2OH^-(aq)$

104. **a.** Ca, +2; C, +4; O, −2
b. Cl, 0
c. Li, +1; I, +5; O, −2
d. Na, +1; S, +4; O, −2

105. **a.** reduction **b.** reduction **c.** reduction
d. oxidation

106. **a.** +4 **b.** +4
c. +3 **d.** +5
e. +5 **f.** +2

107. **a.** The coefficients are 2, 9, 6, and 8.
b. The coefficients are 3, 2, 1, and 3.

108. It is the cell potential when the ion concentrations in the half-cells are 1M, the temperature is 25°C, and the pressure of any gas present is 101.3 kPa.

109. Reduction occurs in the half-cell with the more positive, or less negative, reduction potential. Ni2+ is reduced, and Al is oxidized.
Cell reaction: $3Ni^{2+}(aq) + 2Al(s) \rightarrow 3Ni(s) + 2Al^{3+}(aq)$; $E°_{cell} = +1.66$ V

110. The reaction is nonspontaneous.

111. reduction; reduction

Cumulative Review

*92. Calculate the following quantities:
a. The number of liters occupied at STP by 6.20×10^{-1} mol $Cl_2(g)$
b. The volume of a gas at 3 kPa of pressure if the same gas has a volume of 6 L at 0.5 kPa and the temperature is constant
c. The partial pressure of gas X (P_x) in a mixture of three gases, X, Y, and Z, if the total pressure (P_{total}) is 50 kPa and the sum of the partial pressures of Y and Z is 30 kPa

*93. How many moles of solute are in 750 mL of 1.50*M* KNO_3? How many grams of KNO_3 is this?

94. How many calories are absorbed when 56.0 g of liquid water at 100°C is vaporized to steam?

95. A silver dollar is heated and placed in a foam cup calorimeter containing 50.0 mL of water at 26.5°C. The water reached a maximum temperature of 27.3°C. How many joules of heat were released by the silver dollar?

96. What is the relationship between a calorie and a joule? How many joules is 1 kcal?

97. How does (a) particle size and (b) temperature affect the rate of a chemical reaction?

*98. Explain how the equilibrium position of this reaction is affected by (a) decreasing the temperature and (b) removing CO_2.

$CaCO_3(s) + \text{heat} \rightleftharpoons CaO(s) + CO_2(g)$

99. Write equilibrium constant expressions for the following reactions:
a. $Cl_2(g) + I_2(g) \rightleftharpoons 2ICl(g)$
b. $2HBr(g) \rightleftharpoons H_2(g) + Br_2(g)$
c. $2S_2Cl_2(g) + 2H_2O(g) \rightleftharpoons 4HCl(g) + 3S(g) + SO_2(g)$
d. $N_2(g) + 3H_2(g) \rightleftharpoons 2NH_3(g)$

*100. What are the pH values for aqueous solutions containing each of the following hydroxide-ion concentrations?
a. $1.0 \times 10^{-4}M$ **c.** $0.010M$
b. $3.9 \times 10^{-7}M$ **d.** $0.0050M$

101. A colorless solution of unknown pH turns blue when tested with the acid-base indicator bromothymol blue. It remains colorless when tested with phenolphthalein.
a. What is the approximate pH of the solution?
b. How could you determine the pH more accurately?

*102. Write the formula for each acid or base.
a. phosphoric acid **c.** carbonic acid
b. cesium hydroxide **d.** barium hydroxide

103. Write the reaction for the dissociation of each of the following compounds in water.
a. sodium hydroxide **b.** barium hydroxide

*104. Give the oxidation number of each element in the following substances:
a. $CaCO_3$ **c.** $LiIO_3$
b. Cl_2 **d.** Na_2SO_3

105. Are these processes oxidation or reduction?
a. $Fe^{3+} + e^- \rightarrow Fe^{2+}$
b. $Cl_2 + 2e \rightarrow 2Cl$
c. $Fe^{3+} + 3e^- \rightarrow Fe$
d. $Zn \rightarrow Zn^{2+} + 2e^-$

106. Determine the oxidation number of nitrogen in the following compounds and ions:
a. N_2O_4 **c.** NO_2 **e.** NH_3
b. NO_3^- **d.** NH_4^+ **f.** NO

107. Balance these redox equations.
a. $C_3H_7OH(l) + O_2(g) \rightarrow CO_2(g) + H_2O(l)$
b. $BaO(s) + Al(s) \rightarrow Al_2O_3(s) + Ba(s)$

108. Explain the term *standard cell potential.*

109. A voltaic cell is made of the following half-cells. Determine the cell reaction and calculate the standard cell potential.

$Al^{3+}(aq) + 3e^- \rightarrow Al(s)$ $\quad E°_{Al^{3+}} = -1.66V$

$Ni^{2+}(aq) + 2e^- \rightarrow Ni(s)$ $\quad E°_{Ni^{2+}} = -0.25V$

*110. The calculated standard cell potential for a redox reaction is a negative number. What does a negative number tell you about the reaction?

111. What process always occurs at the cathode of an electrolytic cell? At the cathode of a voltaic cell?

If You Have Trouble With . . .

Standardized Test Prep for Indiana

Standard: C.3.4

Select the choice that best answers each question or completes each statement.

1. What is the name of the compound with the following structural formula?

(A) 1,2,3,3-tetramethylpropane
(B) heptane
(C) 2,4-dimethylpentane
(D) 1,5-dimethylbutane

2. Which of these are characteristic of all alkenes?
I. unsaturated
II. carbon-carbon double bond
III. enantiomers

(A) I and II only
(B) II and III only
(C) I and III only
(D) I, II, and III

3. How many carbon atoms are in a molecule of 4,5-diethyloctane?
(A) 10 (C) 14
(B) 12 (D) 16

4. *Cis-trans* isomerism is possible in
(A) 2-pentene. (C) propyne.
(B) 2-butane. (D) benzene.

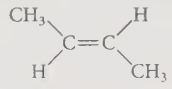
Tips for Success

Eliminate Wrong Answers If you don't know which response to a question is correct, start by eliminating those you know are wrong. If you can rule out some choices, you'll have fewer choices left to consider, which will increase your chances of choosing the correct answer.

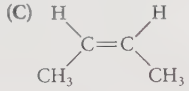
5. A constitutional isomer of heptane is
(A) methylbenzene.
(B) 3,3-dimethylpentane.
(C) cycloheptane.
(D) 3-methylhexene.

6. Which molecule can have enantiomers?
(A) CH_4 (C) $CFClBrI$
(B) CF_2H_2 (D) CF_2ClH

7. Draw structural formulas for three constitutional isomers of pentane, C_5H_{12}. Name each isomer.



8. Write structural formulas for the four constitutional isomers of cyclopentane. Name each of the isomers.



The lettered choices below refer to Questions 9–12. A lettered choice may be used once, more than once, or not at all.
(A) alkene
(B) arene
(C) alkyne
(D) alkane

To which of the above classes of hydrocarbons does each of the following compounds belong?

9. C_7H_{16}
10. C_5H_8
11. C_6H_6
12. C_8H_{16}

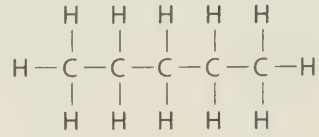
Use the molecular structures below to answer Questions 13–16. A molecular structure may be used once, more than once, or not at all.

(A) 

(C) 

(B) $CH_3CH_2CH_2CH_3$

(D) 



13. Which structure is a cycloalkane?
14. Which structure is a saturated hydrocarbon?
15. Which structure is a *cis*-isomer?
16. Which structure is a *trans*-isomer?

Materials List

For the Student

Quick Lab, p 818
- 1M NaOH
- 5% silver nitrate
- 6M aqueous ammonia
- small test tubes
- test tube rack
- droppers
- glucose solution
- ethanol

Small-Scale Lab, p 828
- 3.5-oz cup
- soda straw
- powdered guar gum
- 4% borax solution
- pipet

For the Teacher

Class Activity, p 799
- 2-propanol
- propanoic or butanoic acid
- butyl amine
- vanillin or cinnamaldehyde
- octyl acetate or ethyl butyrate

Teacher Demo, p 801
- copper wire
- Bunsen burner
- forceps
- bromobenzene
- benzoic acid

Teacher Demo, p 806
- several alcohols
- litmus paper

Class Activity, p 807
- common household products that contain alcohols

Teacher Demo, p 817
- CrO_3
- concentrated sulfuric acid
- water
- 3 test tubes
- acetone
- ethanol
- isopropanol
- *t*-butyl alcohol

Teacher Demo, p 807
- 10 or 15 test tubes with stoppers
- distilled water
- ethanol
- 1-butanol
- 1-hexanol
- 1-octanol
- a hexanediol

Teacher Demo, p 808
- $KMnO_4$
- NaOH
- distilled water
- cyclohexane
- cyclohexene
- 2 test tubes with stoppers

Class Activity, p 813
- benzaldehyde
- isopentyl acetate
- vanillin

Teacher Demo, p 819
- water bath
- hot plate
- test tubes
- several carboxylic acids
- several corresponding alcohols
- concentrated sulfuric acid
- filter paper
- watch glass

IN ACADEMIC STANDARDS for SCIENCE

Nature of Science

- Develop explanations based on reproducible data and observations gathered during laboratory investigations.
- Clearly communicate their ideas and results of investigations verbally and in written form using tables, graphs, diagrams, and photographs.

Standard 4: Reactions and Stoichiometry

C.4.5 Recognize and classify types of reactions.

Also covered C.4.2, C.9.2

Focus on ELL

1 CONTENT AND LANGUAGE Read aloud Essential Question 1, emphasizing the word *effect*. Have students each prepare a cause and effect diagram to organize their answer to this question as they read the chapter. Read aloud Essential Question 2, emphasizing the word *used*. Have students each prepare a cluster diagram to organize their answer to this question as they read the chapter.

BEGINNING

LOW Make a non-linguistic representation of each essential question.

HIGH Allow students to complete the charts in their native language.

INTERMEDIATE: LOW/HIGH Ask students to complete their charts by verbalizing predictions based on their knowledge from Chapter 22.

ADVANCED: LOW/HIGH Have students preview lesson titles, key questions, and vocabulary for information they can use to fill in their charts.

BIGIDEAS

- CARBON CHEMISTRY
- REACTIONS

Essential Questions:

1. *What effect does a functional group have on an organic compound?*
2. *How are chemical reactions used in organic chemistry?*

CHEMYSTERY

The Toothpaste Terror

Yani's little brother, Fernando, is a bit of a menace—especially when it comes to toothpaste. One day Yani walked into the bathroom to find the mirror strewn with ribbons of toothpaste gel. Fernando had wasted almost an entire tube of toothpaste to make his latest "mural."

As Yani began to clean up the mess, she noticed that the toothpaste was still moist even though it had been stuck to the mirror for hours. Why didn't the toothpaste dry out?

▶ Connect to the BIGIDEA As you read about functional groups, think about what ingredient could have kept the toothpaste mural moist.

INDIANA'S ACADEMIC STANDARDS FOR SCIENCE

Reactions and Stoichiometry C.4.2, C.4.5; **Organic Chemistry and Biochemistry** C.9.2. See lessons for details.

Introduce the Chapter

REAL-WORLD CONNECTIONS Students may not realize that many products they frequently use contain compounds with functional groups. Use the activities to relate the chapter to their everyday lives.

Activity 1 *Display a variety of common products that contain alcohols. Examples include hand lotion with propylene glycol, lilac perfume with cinnamic alcohol, toothpaste with glycerol, and shaving lotion with menthol.) Allow students to smell the various products.* **Ask** What do you think all of these products have in common? *(Students may offer various opinions.)* Explain that each of them contains a hydrocarbon with a hydroxy group, —OH.

Activity 2 *You will need small bottles filled with various artificial flavors with the labels covered.* Allow time for students to smell the items and try to guess the flavors. Tell students that all of these contain a hydrocarbon with a group called an ester. Draw an ester group on the board. Explain that each flavor depends on the organic compound to which the ester group is attached.

UbD

Understanding by Design

Students are building toward understanding chemical reactions in carbon chemistry using the relationships between organic compounds and their functional groups.

PERFORMANCE GOALS At the end of Chapter 23, students will be able to answer the essential questions by applying their knowledge of functional groups. Students will also be able to explain how polymers are formed through addition and condensation reactions.

ESSENTIAL QUESTIONS Read the essential questions aloud. **Ask** What is the charge of a halogen? *(1–)* **Ask** How do you think an alkane (with only single bonds) might be affected if you replaced one of its hydrogen atoms with a halogen atom? *(The product would have greater mass and a higher boiling point.)* **Ask** What other effects do you think replacing an atom of a hydrocarbon with another atom or group of atoms might have? *(Sample answer: It might affect the solubility of a compound or its odor.)* **Ask** How do you think adding a group of atoms to an alkene, which has double bonds, might be able to change it to an alkane? *(An added atom might attach to one of the double-bonded carbon atoms, reducing the carbon-carbon double bond to a single bond.)*

BIGIDEA Use the photo of the spices to help students connect to the concepts they will learn in this chapter. Activate prior knowledge by asking students which spices they use or like in various foods. **Ask** What do you think might make them different? *(They must have some atoms or groups of atoms that give them different scents and flavors.)*

CHEMYSTERY Have students read over the CHEMystery. Connect the CHEMystery to the Big Idea of Carbon Chemistry and Chemical Reactions by reminding students that chemical reactions create new products with different properties from the reactants. Note that sometimes this change can be achieved by replacing a single atom or by joining whole molecules together. Ask students to predict why the toothpaste did not dry out. As a hint, have students look at the ingredients lists of several tubes of toothpaste.

LESSON 23.1

Key Objectives

23.1.1 EXPLAIN how organic compounds are classified.

23.1.2 IDENTIFY the general formula of a halocarbon.

23.1.3 DESCRIBE how substitution reactions are used in organic chemistry.

Additional Resources

Engage

CHEMISTRY & YOU Direct students to the photograph and the text that opens the lesson.
Ask Using the context of the band, predict how the functional groups determine the character of organic compounds. *(Each functional group has certain chemical properties that affect the behavior of any compound that contains the functional group.)*

Activate Prior Knowledge

Have students review what they know about hydrocarbons and substituents from Chapter 22. Explain that in this lesson, students will explore non-carbon substituents and the reactions that are used to add them to hydrocarbons.

Foundations for Reading

BUILD VOCABULARY Use set notation or a Venn diagram to convey the interrelationship among the vocabulary words.

IN ACADEMIC STANDARDS for SCIENCE

C.4.2 Balance chemical equations using the law of conservation of mass and use them to describe chemical reactions.

C.4.5 Describe, classify and give examples of various kinds of reactions-synthesis (combination), decomposition, single displacement, double displacement and combustion.

C.9.2 Identify the variety of molecular types formed by the covalent bonding of carbon atoms and describe the typical properties of these molecular types.

23.1 Introduction to Functional Groups

C.4.5 Classify types of reactions; C.9.2 Identify the variety of carbon molecules **Also covered** C.4.2.

CHEMISTRY & YOU

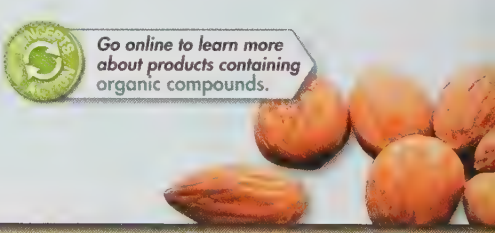
Q: *How can you tell the difference between one organic compound and another?* If you've ever seen a marching band, you know that all the members wear the same uniform. From a distance, all the musicians look nearly identical. But are they? If you look more closely, you can distinguish their differences by the instruments they hold. In a similar way, one hydrocarbon is nearly identical to another until it is distinguished by a functional group.

Key Questions

- ***How are organic compounds classified?***
- ***What is the general formula of a halocarbon?***
- ***How are substitution reactions used in organic chemistry?***

Vocabulary

- functional group
- halocarbon
- alkyl halide
- aryl halide
- substitution reaction



Functional Groups

How are organic compounds classified?

In Chapter 22, you learned about the essential components of every organic compound: hydrocarbon chains and rings. In most organic reactions, the saturated hydrocarbon skeletons of molecules are chemically inert, or nonreactive. So how, then, can there be hundreds of different kinds of organic reactions?

Most organic chemistry involves substituents, which are groups attached to hydrocarbon chains or rings. The substituents of organic molecules often contain oxygen, nitrogen, sulfur, and/or phosphorus. They are called functional groups because they are the chemically functional parts of the molecules. A **functional group** is a specific arrangement of atoms in an organic compound that is capable of characteristic chemical reactions. Most organic chemistry involves the functional groups of organic molecules. Note that the double and triple bonds of alkenes and alkynes are chemically reactive. Therefore, double and triple carbon-carbon bonds are considered functional groups.

Organic compounds can be classified according to their functional groups. Table 23.1 identifies the functional groups that you will learn about in this chapter. You will find it helpful to refer to this table as new functional groups are introduced. In each general structure listed, the symbol R represents any carbon chains or rings attached to the functional group. In some cases, R can be a hydrogen atom. When more than one R group is shown in the structural formula, the groups do not need to be the same. Figure 23.1 shows several consumer products containing organic compounds with various functional groups.

Go online to learn more about products containing organic compounds.

Focus on ELL

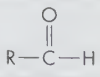
1 CONTENT AND LANGUAGE Rephrase the key questions on the board using familiar synonyms for *classified* and *general*. Explain how you substituted one word in the question for another to help explain the meaning of substitution.

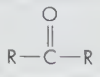
2 FRONTLOAD THE LESSON Ask the class to preview Table 23.1. Make sure students understand that the letter "R" in each the structure in the middle column represents a hydrocarbon segment or chain. Ask students to find the sentence or sentences in the lesson that refer to Table 23.1. Discuss the meaning of the sentences.

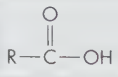
3 COMPREHENSIBLE INPUT When discussing the Substitution Reactions section, rewrite the example equations by expanding the condensed formulas into structural formulas. Use different colors for each reactant and carry these colors into the products.

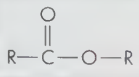
Table 23.1

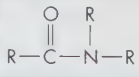
Organic Compounds Classified by Functional Group











Compound type	General structure	Functional group
Halocarbon	R—X (X = F, Cl, Br, or I)	Halogen
Alcohol	R—OH	Hydroxy
Ether	R—O—R	Ether
Amine	$R—NH_2$	Amino
Aldehyde		Carbonyl
Ketone		Carbonyl
Carboxylic acid		Carboxyl
Ester		Ester
Amide		Amide

Figure 23.1 Consumer Products Many items contain hydrocarbon derivatives. The hydrocarbon skeletons in these products are chemically similar. Functional groups give each product unique properties and uses.

UbD Check for Understanding

How are organic compounds classified?

Assess students' understanding about the classification of organic compounds by drawing various functional groups on the board, and ascertaining via a thumbs-up/thumbs-down test whether students know the identity of each one.

ADJUST INSTRUCTION If students are indicating a significant number of thumbs-down responses, have them review Table 23.1. Repeat the exercise until all students consistently recognize functional groups by their names and structures.

Explain

Functional Groups

START A CONVERSATION Stress the importance of structure in the chemistry of organic molecules. Explain that molecular shape is dictated by bonding functional groups. **Ask** How does the structure of a molecule relate to its taste or smell? *(Both senses rely on the ability of chemoreceptor molecules on cell surfaces, which recognize a molecule by its shape.)*

USE VISUALS Have students examine Table 23.1 for patterns and relationships. Convey the meaning of the symbols *R* and *X*, and encourage students to memorize the general compound structure for each functional group. List specific examples of compounds for each functional group to help students become more familiar with these groups in larger molecules. **Ask** Why are the carbon–carbon double and triple bonds considered to be functional groups? *(They are chemically reactive.)* **Ask** What do most of the functional groups in the table have in common? *(Most functional groups contain oxygen.)*

Explore

Class Activity

PURPOSE Students will learn that compounds containing the same functional group have similar chemical and physical properties.

MATERIALS 2-propanol, propanoic or butanoic acid, butyl amine, vanillin or cinnamaldehyde, octyl acetate or ethyl butyrate

SAFETY Have students carefully waft vapors of the compounds in order to detect their odors. Remind students that normally it is not safe to smell chemicals. An exception is being made for these known compounds.

PROCEDURE Bring samples of organic compounds to class. Allow students to observe the characteristic odors associated with alcohols (2-propanol), acids (propanoic or butanoic acid), amines (butyl amine), aldehydes (vanillin or cinnamaldehyde), and esters (the orange odor of octyl acetate and the pineapple odor of ethyl butyrate). Have students record their observations, and then make a summary table on the board. Ask students to consider what other properties molecules with the same functional groups might have in common.

Explain

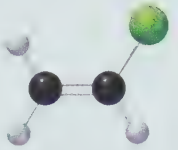
Halocarbons

USE VISUALS Direct students' attention to Table 23.2. Display the table using a transparency and overhead projector and discuss the rules for naming alkyl halides. Create large examples of primary, secondary, tertiary, vinyl, and aryl halides on sheets of paper and display them around the classroom. Help students to recognize the alkyl portion of the molecule by circling it in a different color of chalk. Write the structure of the original parent hydrocarbon next to the alkyl halide. Allow pairs of students to go on a gallery walk to review these examples up close. At each example station, students should actively be adding to their notes.

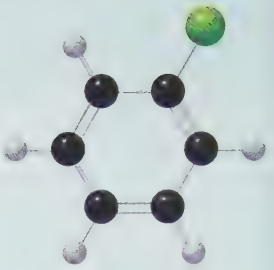
USE CONTEXT CLUES After students have mastered the meaning of the terms *primary, secondary,* and *tertiary,* show them the derivation of the common names: *sec*-butylbromide and *tert*-butylbromide.

Explore

Class Activity



Divide the class into groups of two or three students. Have each group practice naming halocarbons from structural formulas and writing structural formulas from their names. Students in each group should take turns devising questions and giving answers.

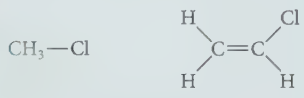


Extend

Use examples from the discussion on halogen substitution to show how a chemist can start with a simple alkane, change it to an alkyl halide, then change the halide to an alcohol. Point out that this is one way organic chemists synthesize molecules that are not found in nature. Have students research one such reaction and write a chemical equation to represent the reaction.

Figure 23.2 Halocarbons A halocarbon is a carbon-containing compound with a halogen substituent.
Classify *Are these halocarbons alkyl halides or aryl halides?*

Chloromethane



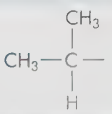
Chloroethene

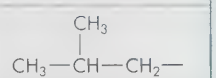
Chlorobenzene

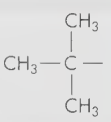
Halocarbons

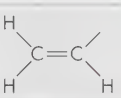
What is the general formula of a halocarbon?

A **halocarbon** is an organic compound that contains at least one covalently bonded fluorine, chlorine, bromine, or iodine atom. **The general formula of a halocarbon is RX, where X is a halogen substituent.** The IUPAC rules for naming halocarbons are based on the name of the parent hydrocarbon. The halogen groups are named as substituents. Examples of IUPAC names for some simple halocarbons are shown below. The common names are given in parentheses. Figure 23.2 shows the ball-and-stick models for these halocarbons.









Chloromethane (methyl chloride) | Chloroethene (vinyl chloride) | Chlorobenzene (phenyl chloride)

Common names of halocarbons consist of two parts. The first part names the hydrocarbon portion of the molecule as an alkyl group, such as *methyl-* or *ethyl-*. The second part names the halogen with an *-ide* ending. On the basis of their common names, a halocarbon in which a halogen is attached to a carbon of an aliphatic chain is called an **alkyl halide.** A halocarbon in which a halogen is attached to a carbon of an arene ring is called an **aryl halide.** Table 23.2 lists the names of some substituent groups other than methyl, ethyl, and propyl.

The attractions between halocarbon molecules are primarily the result of the weak van der Waals interactions. Generally, these attractions increase with the degree of halogen substitution. This means that more highly halogenated organic compounds have higher boiling points, as illustrated in Table 23.3.

Very few halocarbons are found in nature, but they can be readily prepared and used for many purposes. For example, hydrofluorocarbons (HFCs) are used as refrigerants in automobile air-conditioning systems. Halocarbons are also used as solvents and as ingredients of stretchable polymers.

Table 23.2
Some Common Substituent Groups

Name	Group structure
Isopropyl	
Isobutyl	
Secondary butyl (*sec*-butyl)	
Tertiary butyl (*tert*-butyl)	
Vinyl	
Phenyl	

Differentiated Instruction

ELL ENGLISH LANGUAGE LEARNERS Encourage students to practice writing and then naming the structures of 1-, 2-, and 3-carbon alkyl halides. Have them build a model of one of these structures and discuss how it is produced from the corresponding alkane.

L1 STRUGGLING STUDENTS Explain that students used the concept of substitution when they learned to evaluate an expression in algebra; i.e., evaluate $3xy + 2x$ for $x = 3$ and $y = 4$. Show students how this concept is analogous to substitution reactions.

L3 ADVANCED STUDENTS Have students research examples in which the structure of a chemical plays an important role in a biological process. Suggestions for research include neurotransmitters, such as acetylcholine, and hormones, such as estradiol and testosterone. Have students research how environmental pollutants can interfere with the action of these natural chemicals.

Table 23.3

Comparing Methane and Chloromethanes

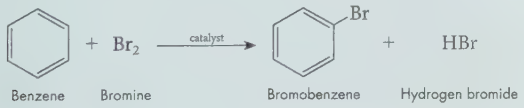
Molecular formula	Name	Molar mass (g)	Boiling point (°C)
CH_4	Methane	16.0	−161
CH_3Cl	Chloromethane (methyl chloride)	50.5	−24
CH_2Cl_2	Dichloromethane (methylene chloride)	85.0	40
$CHCl_3$	Trichloromethane (chloroform)	119.5	61
CCl_4	Tetrachloromethane (carbon tetrachloride)	154.0	74

Substitution Reactions

How are substitution reactions used in organic chemistry?

Organic reactions often proceed more slowly than inorganic reactions because organic reactions commonly involve the breaking of relatively strong covalent bonds. They often require catalysts. Many organic reactions are complex, and they usually give a mixture of products. The desired product must then be separated by distillation, crystallization, or other means. A common type of organic reaction is a **substitution reaction,** in which an atom, or a group of atoms, replaces another atom or group of atoms.

Substitution reactions are an important method of introducing new functional groups to organic molecules. For example, a halogen atom can replace a hydrogen atom on an alkane to produce a halocarbon. The symbol X stands for a halogen in this generalized equation.



$$\underset{\text{Alkane}}{R{-}H} + \underset{\text{Halogen}}{X_2} \longrightarrow \underset{\text{Halocarbon}}{R{-}X} + \underset{\text{Hydrogen halide}}{HX}$$

From the generalized equation, you can write a specific one. This type of reaction is also called a halogenation reaction because the reaction introduces a halogen atom into the molecule. Sunlight or another source of ultraviolet radiation usually serves as a catalyst.

$$\underset{\text{Methane}}{CH_4} + \underset{\text{Chlorine}}{Cl_2} \xrightarrow{\text{UV light}} \underset{\text{Chloromethane}}{CH_3Cl} + \underset{\text{Hydrogen chloride}}{HCl}$$

Even under controlled conditions, this simple substitution reaction produces a mixture of mono-, di-, tri-, and tetrachloromethanes.

Halogenation of benzene in the presence of a catalyst causes the substitution of a hydrogen atom on the ring. Iron compounds are often used as catalysts for substitution reactions in aromatic compounds.

Tetrachloroethylene

Tetrachloroethylene (formerly called perchloroethylene, perc, or PCE) is a manufactured solvent used in about 95 percent of dry cleaning businesses in the United States. For years it has been the subject of close government and public scrutiny as a possible carcinogen. Recently, the Department of Health and Human Services determined that tetrachloroethylene may reasonably be considered to be a carcinogen. The National Institute for Occupational Safety and Health (NIOSH) recommends that tetrachloroethylene be handled as a possible carcinogen and recommends that exposure levels at the workplace be as low as possible. The Occupational Safety and Health Administration (OSHA) has a limit of 100 ppm for an 8-hour workday over a 40-hour workweek in order to protect those people having to work in this environment.

Explain

Substitution Reactions

USE VISUALS Direct students to Table 23.3. Point out that the subscript on the chlorine molecule in each molecular formula increases from 0 to 4. Have students look for a trend in boiling-point temperatures. **Ask** What can you infer about the cause of this pattern in boiling-point temperatures? *(The more halogen substituents a molecule has, the greater will be the attraction of the molecule to other halocarbon molecules.)*

Explore

PURPOSE Students will observe the Beilstein test for determining the presence of halogen functionalities in organic compounds. Point out that organic chemists often perform qualitative chemical tests to identify unknown organic compounds.

SAFETY Wear safety goggles and a laboratory apron while performing the demo.

MATERIALS copper wire, Bunsen burner, forceps, bromobenzene, benzoic acid

PROCEDURE Prepare a piece of copper wire with a small loop in one end. Heat the loop in a Bunsen burner flame and allow the wire to cool. Next, dip the loop into a sample of aryl halide (bromobenzene). Heat the wire in the flame again. Repeat the test with a negative control, benzoic acid.

EXPECTED OUTCOMES A green flame will be produced with bromobenzene, indicating the presence of a halogen. The flame will not be green when testing benzoic acid.

Answers

FIGURE 23.2 Chloromethane and chloroethene are alkyl halides. Chlorobenzene is an aryl halide.

LESSON 23.1

Explore

Substitution Reactions

MAKE A CONNECTION Explain that when triglycerides are combined with aqueous sodium hydroxide, the products are glycerol and fatty acid salts. This process is called *saponification*. Encourage interested students to look ahead in Chapter 24 to discover how the concepts learned in this lesson translate to the study of lipids.

Extend

Ask students to prepare a computer slideshow presentation explaining how it is beneficial to be able to deduce the properties of halogens from what we know about them as a functional group. Presentations should show several real-world applications that have benefited society. Presentations should convey the various uses of halocarbons: anesthetics, cleaning agents, non-stick surfaces, pipes and other plastic items, and refrigerants.

Evaluate

Informal Assessment

Write the structural formulas for ethene, chloroethane, and ethanol on the board. Ask students to name the compounds and identify their functional groups. *(double bond, halogen, hydroxy group)* Ask students to choose two of the compounds to illustrate a substitution reaction. *(Hydroxide ions can replace the chlorine in ethyl chloride to form ethanol.)*

Reteach

Work with students to construct a concept map showing the connection between alkanes and their derivatives: alkenes, alkynes, halocarbons, and alcohols. Use propane as a specific example and start with the heading *alkanes*. Write the structural formula for the propyl derivative in each case.

Lesson Check Answers

1. according to their functional groups
2. RX, where X is a covalently bonded halogen substituent such as fluorine, chlorine, bromine, or iodine
3. They are used to introduce new functional groups to organic molecules.
4. **a.** —OH, hydroxy group; alcohol
   b. —NH_2, amino group; amine
   c. —COOH, carboxyl group; carboxylic acid
   d. —Br, halogen; halocarbon
   e. —C—O—C—, ether group; ether
   f. —I, halogen; halocarbon

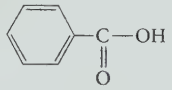
CHEMISTRY & YOU

Q: *Earlier you learned that adding a halogen substituent to a hydrocarbon affects certain physical properties. How can you distinguish between hydrocarbons and halocarbons in terms of structures and properties?*

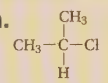
Halocarbons can be converted to other types of compounds by substitution reactions. For example, hydroxide ions can displace halogen atoms on carbon chains to form an alcohol. (Fluorine is one exception. Because fluoro groups are not easily displaced, they are seldom used to prepare alcohols.) The general reaction for the formation of an alcohol from a halocarbon is as follows:

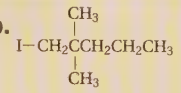
$$\underset{\text{Halocarbon}}{R{-}X} + \underset{\text{Hydroxide ion}}{OH^-} \xrightarrow[100°C]{H_2O} \underset{\text{Alcohol}}{R{-}OH} + \underset{\text{Halide ion}}{X^-}$$

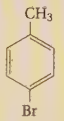
Chemists usually use aqueous solutions of sodium hydroxide or potassium hydroxide as the source of hydroxide ions. The chemical equation for two specific examples are shown below.

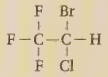


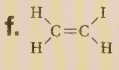
$$\underset{\text{Iodomethane}}{CH_3{-}I(l)} + \underset{\substack{\text{Potassium}\\\text{hydroxide}}}{KOH(aq)} \xrightarrow{100°C} \underset{\text{Methanol}}{CH_3{-}OH(l)} + \underset{\substack{\text{Potassium}\\\text{iodide}}}{KI(aq)}$$











$$\underset{\text{Bromoethane}}{CH_3CH_2Br(l)} + \underset{\substack{\text{Sodium}\\\text{hydroxide}}}{NaOH(aq)} \xrightarrow{100°C} \underset{\text{Ethanol}}{CH_3CH_2OH(l)} + \underset{\substack{\text{Sodium}\\\text{Bromide}}}{NaBr(aq)}$$

Halocarbons can also be converted to other halocarbons, amines, or ethers by similar substitution reactions.

ONLINE PROBLEMS

23.1 LessonCheck

1. **Review** How are organic compounds classified?
2. **Identify** What is the general formula of a halocarbon?
3. **Explain** Why are substitution reactions useful in organic chemistry?
4. **Classify** Identify the functional group in each structure. Then classify the compound according to its functional group.
   a. $CH_3{-}OH$
   b. $CH_3{-}CH_2{-}NH_2$
   c. 
   d. $CH_3{-}CH_2{-}CH_2{-}Br$
   e. $CH_3{-}CH_2{-}O{-}CH_2{-}CH_3$
   f. $CH_3{-}CH_2{-}I$
5. **Describe** Draw a structural formula for each compound listed below.
   a. isopropyl chloride
   b. 1-iodo-2,2-dimethylpentane
   c. *p*-bromotoluene
   d. bromoethene
   e. 2-bromo-2-chloro-1,1,1-trifluoroethane
   f. vinyl iodide
6. **Compare** How would you expect the boiling points of ethane and chloroethane to compare? Explain your answer.
7. **Apply Concepts** Draw the structural formulas and write the IUPAC names of all possible dichloropropanes that could result from a substitution reaction involving chlorine and propane.
8. **Describe** Write a balanced chemical equation for the preparation of 2-propanol from potassium hydroxide and 2-bromopropane.

5. **a.** 
   b. 
   c. 
   d. 
   e. 
   f. 
6. Chloroethane would have a higher boiling point because of the increased strength of the interactions between halocarbon molecules compared to those between hydrocarbons.
7. $CHCl_2CH_2CH_3$, 1,1-dichloropropane
   $CH_2ClCHClCH_3$, 1,2-dichloropropane
   $CH_3CCl_2CH_3$, 2,2-dichloropropane
   $CH_2ClCH_2CH_2Cl$, 1,3-dichloropropane
8. $CH_3CHBrCH_3 + KOH \rightarrow CH_3CHOHCH_3 + KBr$

PCBs: A Persistent Pollutant

Even though that tuna you're eating for dinner might be freshly caught, it still could be contaminated by a toxic industrial chemical that hasn't been manufactured in the U.S. in over 30 years! These chemicals, called polychlorinated biphenyls (PCBs), do not break down easily, and therefore persist wherever they end up for long periods of time.

PCBs are aromatic halocarbons that were used in a variety of industrial applications, including electrical transformers, hydraulic fluids, and carbonless copy paper. The chemicals, which were banned in 1979, accumulated as waste in the sediments and water of rivers, lakes, and oceans. Organisms that live in the water ingest the chemicals, which can build up over time in their fatty tissues. This buildup can be passed up the food chain. At the top of the food chain, PCBs levels can be from 100,000 to 1,000,000 times higher than the original environmental levels.

Although the amount of PCBs from a single meal is not harmful, continued low levels of exposure may lead to various health issues, including cancer.

MAGNIFYING THE EFFECT
Organisms that are higher up in the food chain can accumulate greater PCB concentrations than organisms that are lower in the food chain. The series to the right shows typical PCB levels for each member in units of parts per billion (ppb).

Take It Further

1. Identify PCBs are biphenyls with one to ten chlorine atoms attached. Draw structural formulas of five different PCBs.

2. Infer Polychlorinated biphenyls are heat stable, nonflammable, and have high electrical resistance. Based on these properties, why might companies have used PCBs as insulating materials and thermal conductors?

21st Century Learning To be successful in the 21st century, students need skills and learning experiences that extend beyond subject matter mastery. The following project helps students build the following 21st Century Skills: *Financial, Economic, Business, and Entrepreneurial Literacy*; *Creativity and Innovation*; *Communication and Collaboration*; *Information, Media, and Technology Literacy*; *Initiative and Self-Direction*; and *Productivity and Accountability*.

YOU ARE WHAT YOU EAT! Pose the following challenge to your students. *The EPA wants to convey that a clean-up effort in one of the Great Lakes has resulted in a dramatic reduction of PCBs in its fish population. They have hired you to create a video-taped public service announcement to explain the circumstances leading to the agency's removal of this lake's fish from its watch list.* The announcement should demonstrate an awareness of the environment as it relates to PCBs and how they affect an aquatic ecosystem.

CHEMISTRY & YOU Discuss with students the affects of PCBs on various ecosystems or food chains. Direct students' attention to the diagram of the food chain and have them read the accompanying text. Explain that biologists refer to the accumulation of toxins in each successive trophic level of an ecosystem as *biological magnification*.

Pose the following question to students. ***If humans are at the top of this food chain, how are they affected by the biological magnification of PCBs in aquatic food webs?*** You may need to assist students in the following ways:

- The greatest levels of PCBs are found in fresh and saltwater sportfish species, such as the bluefin tuna shown in the diagram.
- Human consumption of PCBs can lead to skin and liver disorders, cancer, low infant birth weights, and developmental delays in children.
- One part per billion (ppb) is another way of representing one microgram per kilogram (μg/kg).

MAKE A CONNECTION Have students research the concept of half life and find out what the approximate half life is for PCBs in marine animals. Have students use the concept of half life to explain why PCBs pose a risk to humans for a very long time.

Connect to GOVERNMENT

Have students research and identify the two federal agencies that have responsibility in protecting humans from exposure to harmful levels of PCBs. Students should determine the regulations set in regard to PCBs. *(FDA—the allowable level of PCBs is currently 2.0 ppm for fish and shellfish. EPA—the limit for all PCBs in fish tissue is 0.01 ppm.)* Have students also determine other examples of industrial contamination for which these agencies have had to implement standards in order to protect human health. *(Sample answers: lead, mercury, and other heavy metals)*

Answers

TAKE IT FURTHER

1. Check students' structural formulas.
2. It is desirable that the items do not melt or catch fire when exposed to heat or a nearby flame or spark.

LESSON 23.2

Key Objectives

23.2.1 IDENTIFY the general formula of an alcohol.

23.2.2 DESCRIBE how addition reactions are used in organic chemistry.

23.2.3 IDENTIFY the general formula of an ether.

23.2.4 IDENTIFY the general formula of an amine.

Additional Resources

- Reading and Study Workbook, Lesson 23.2

PearsonChem.com

Engage

CHEMISTRY & YOU Pass out mints for students to smell, taste, and observe, and then direct them to the opening text and photograph. Ask students to compare the sensations of aftershaves or muscle rubs on their skin to that from the candy in their mouths.

Access Prior Knowledge

Prior to beginning the lesson, have students create a KWL chart about what they already know about organic chemistry and functional groups. Have students continue their charts as they proceed with the lesson.

Foundations for Reading

BUILD VOCABULARY To help students relate vocabulary to concepts discussed in this section, have them distinguish between hydration and hydrogenation. Although both terms come from the same root word, hydration is the addition of water, whereas hydrogenation is the addition of hydrogen.

IN ACADEMIC STANDARDS for SCIENCE

C.4.5 Describe, classify and give examples of various kinds of reactions-synthesis (combination), decomposition, single displacement, double displacement and combustion.

23.2 Alcohols, Ethers, and Amines

C.4.5 Classify types of reactions

CHEMISTRY & YOU

Q: *How can organic chemistry cool you down?* Aftershave lotion contains a certain organic compound that imparts a cooling sensation on the skin. The same ingredient can be found in mint-flavored candy, cough drops, and muscle rubs. In this lesson, you'll read about three classes of organic compounds that have a wide variety of uses.

Key Questions

- ***What is the general formula of an alcohol?***
- ***How are addition reactions used in organic chemistry?***
- ***What is the general formula of an ether?***
- ***What is the general formula of an amine?***

Vocabulary

- alcohol
- hydroxy group
- fermentation
- addition reaction
- hydration reaction
- hydrogenation reaction
- ether
- amine

Alcohols

What is the general formula of an alcohol?

What do mouthwash, perfume, and hairspray have in common? They all contain an alcohol of some type. An **alcohol** is an organic compound with an —OH group. **The general formula of an alcohol is ROH.**

Alcohol

The —OH functional group in alcohols is called a **hydroxy group,** sometimes called a hydroxyl group. The oxygen atom in the —OH group has two pairs of nonbonding electrons, which compress the R—O—H bond angle. As a result, an alcohol functional group has a bent shape.

Aliphatic alcohols can be classified into structural categories according to the number of carbons attached to the carbon with the hydroxy group. If only one carbon (or no carbon) is attached to C—OH, the latter carbon is considered a primary carbon, and the alcohol is a primary alcohol. If two carbons are attached, the carbon is a secondary carbon, which gives a secondary alcohol; if three carbons, a tertiary carbon, and a tertiary alcohol. This nomenclature is summarized below using R to represent any carbon chains or rings.

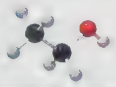
Primary alcohol	$R{-}CH_2{-}OH$	Only one R group is attached to C—OH of a primary (abbreviated 1°) alcohol.
Secondary alcohol	$R{-}\underset{\displaystyle R}{\overset{}{\underset{}{CH}}}{-}OH$	Two R groups are attached to C—OH of a secondary (2°) alcohol.
Tertiary alcohol	$R{-}\underset{\displaystyle R}{\overset{\displaystyle R}{\underset{}{C}}}{-}OH$	Three R groups are attached to C—OH of a tertiary (3°) alcohol.

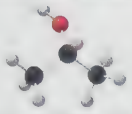
Focus on ELL

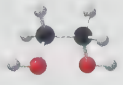
1 CONTENT AND LANGUAGE Write the suffixes *-tion* and *-ation* on the board. Explain that these two suffixes both mean "action or process." Have students identify the vocabulary terms containing these suffixes and use their definition to define the vocabulary terms.

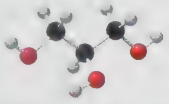
2 FRONTLOAD THE LESSON Review the vocabulary and key questions from Lesson 23.2. Ask students to recall and draw the functional groups for alcohols, ethers, and amines.

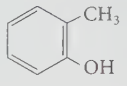
3 COMPREHENSIBLE INPUT Use the Kinetic Art feature to show students animated examples of addition reactions. Help students understand the process of naming ethers by highlighting the two R groups with different colors, using the same color to represent the smaller group each time.

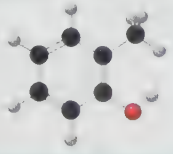












Naming Alcohols Both IUPAC and common names are used for alcohols. To name aliphatic alcohols using the IUPAC system, drop the *-e* ending of the parent hydrocarbon name and add the ending *-ol*. The parent hydrocarbon is the longest continuous chain of carbons that includes the carbon attached to the hydroxy group. In numbering the parent hydrocarbon, the position of the hydroxy group is given the lowest possible number. Some alcohols have more than one hydroxy group. To name these alcohols using the IUPAC system, simply add the ending *-diol* or *-triol*, to the parent hydrocarbon name if the alcohol has two or three hydroxy groups, respectively.

The common names of aliphatic alcohols are written in the same way as those of halocarbons. The alkyl group ethyl, for example, is named and followed by the word *alcohol*, as in *ethyl alcohol*. The common name for an alcohol with two hydroxy groups is a glycol.

When the hydroxy group is attached directly to an aromatic ring, the compound is called a phenol. To assign the IUPAC name, phenol is used as the parent hydrocarbon. For example, a phenol with a methyl group attached is called a methylphenol. Cresol is the common name for the *o*, *m*, and *p* constitutional isomers of methylphenol. Table 23.4 lists the names, structural formulas, and ball-and-stick models of some simple alcohols and phenols.

Table 23.4

Some Common Alcohols and Phenols

IUPAC name (common name)	Structural formula	Ball-and-stick model
Ethanol (ethyl alcohol)	$CH_3—CH_2—OH$	
2-propanol (isopropyl alcohol)	$CH_3—\underset{\displaystyle OH}{\underset{\vert}{CH}}—CH_3$	
1,2-ethanediol (ethylene glycol)	$\underset{\displaystyle OH}{\underset{\vert}{CH_2}}—\underset{\displaystyle OH}{\underset{\vert}{CH_2}}$	
1,2,3-propanetriol (glycerol)	$\underset{\displaystyle OH}{\underset{\vert}{CH_2}}—\underset{\displaystyle OH}{\underset{\vert}{CH}}—\underset{\displaystyle OH}{\underset{\vert}{CH_2}}$	
2-methylphenol (*o*-cresol)		

Antifreeze Poisoning

Every year, about 10,000 dogs and cats are victims of accidental poisoning by automobile antifreeze. A pet does not have to drink a lot of antifreeze to be poisoned. Most brands of commercial antifreeze consist of 95 percent ethylene glycol, an extremely toxic chemical. Even a few licks of this sweet-tasting liquid can be fatal to a cat or dog. For a medium-sized dog, ingestion of about 3 to 4 tablespoons of antifreeze is toxic. For cats, as little as 1 to 2 teaspoons can be lethal. Antifreeze poisoning commonly occurs in spring and fall when car owners replace the old antifreeze in their car radiators with fresh antifreeze. However, poisoning can happen anytime, particularly when a car boils over or when a hose leaks, releasing the antifreeze.

READING STRATEGY Have students write a short paragraph comparing structural formulas and ball-and-stick models. Students should explain what information each representation best shows about a compound and what each representation does not show.

Explain

Alcohols

APPLY CONCEPTS Explain that many biochemically active molecules contain carbon atoms bonded to oxygen atoms. Point out that the presence of a single oxygen atom significantly alters the chemical and physical properties of a hydrocarbon. Explain that alcohols and ethers are two important classes of organic compounds that contain oxygen.

MAKE A CONNECTION Discuss the IUPAC conventions for naming aliphatic alcohols. Write the condensed structural formulas of several primary, secondary, and tertiary alcohols on the board, and help students to name them. Remind students how to distinguish primary, secondary, and tertiary carbons. Write the structures of methanol, ethanol, and isopropyl alcohol on the board and point out that students already know a lot about the uses and properties of these alcohols. Help students name the structures shown. **Ask** What are some everyday examples where these alcohols are used? *(Methanol is a good fuel for internal combustion engines; it is sometimes used for race cars. Methanol is also an excellent solvent, and is used for paints, shellacs, and varnishes. Ethanol is found in alcoholic beverages and is sometimes used as a gasoline additive to produce cleaner burning fuels. Isopropyl alcohol is used as an antiseptic—rubbing alcohol.)* **Ask** How does a hydroxy group differ from a hydroxide ion? *(The bonding between carbon and the hydroxy group in alcohols is covalent. The bonding between a metal and the hydroxide ion in bases is ionic.)*

Explain

Alcohols

USE MODELS Write the structure of water and the general structures of alcohols and ethers on the board. Point out that alcohols and ethers can be viewed as derivatives of water. Allow students to handle ball-and-stick and space-filling models of water, ethanol, and diethyl ether. Write the condensed structural formula for each on the board. **Ask** What are the structural similarities between all three compounds? *(Students should identify the bent geometry around the oxygen atom.)* **Ask** What significance does this bent shape have for the overall polarity of the molecules? *(Each O—H and O—C bond is polar. Because the molecules are bent, the bond polarities do not cancel, and the molecules as a whole are polar. The region around the oxygen atom has a slight negative charge.)*

CRITICAL THINKING Point out that the polar character of alcohols and ethers is tempered by the alkyl groups, which are nonpolar. Challenge students to name the important intermolecular forces holding molecules together in alcohols and ethers. **Ask** How are water, ethanol, and diethyl ether ranked in order of increasing boiling point? *(Ether, ethanol, water; ether molecules are attracted to one another by intermolecular dipolar attractions, while ethanol and water molecules have strong intermolecular hydrogen bonding.)*

Explore

Teacher Demo

PURPOSE Students will observe that, although alcohols contain —OH groups, they are not hydroxides.

MATERIALS several alcohols, litmus paper

PROCEDURE Test several alcohols with litmus paper to show that they have no basic properties.

Properties of Alcohols Alcohols are capable of intermolecular hydrogen bonding, which is reflected in their physical properties. For example, alcohols boil at higher temperatures than alkanes and halocarbons containing a comparable number of atoms.

Because alcohols are derivatives of water (the hydroxy group is part of a water molecule), they are somewhat soluble in water. Alcohols with up to four carbons are completely soluble in water. The solubility of alcohols with more than four carbons in the chain is usually much lower. This is because alcohols consist of two parts—the carbon chain and the hydroxy group. The carbon chain is nonpolar and is not attracted to water. The hydroxy group is polar and strongly interacts with water through hydrogen bonding. For alcohols of up to four carbons, the polarity of the hydroxy group overpowers the nonpolarity of the carbon chain. As a result, these alcohols are soluble in water. As the number of carbon atoms increases above four, however, the nonpolarity of the carbon chain dominates, and the solubility of the alcohol decreases.

Uses of Alcohols Figure 23.3 illustrates some common uses of alcohols. For example, 2-propanol, which is more familiarly known as rubbing alcohol, is often used as an antiseptic. It is also used as a base for perfumes, creams, lotions, and other cosmetics. Another alcohol, 1,2,3-propanetriol, is highly soluble in water because it has three hydroxy groups. It also has a tendency to absorb water from its surroundings. This quality makes 1,2,3-propanetriol a valuable moistening agent in cosmetics, foods, and pharmaceuticals.

Some antifreezes use 1,2-ethanediol as the main ingredient. This alcohol has a high boiling point, 197°C, which helps prevent vehicle engines from overheating. Its advantages over other liquids with high boiling points are its solubility in water and its low freezing point, −17.4°C. When water is added to 1,2-ethanediol, the mixture freezes at even lower temperatures. For example, a 50% (v/v) aqueous solution of 1,2-ethanediol freezes at −36°C. This property also makes 1,2-ethanediol an effective anti-icing agent.

Figure 23.3 Uses of Alcohols
Alcohols are used in many common products. **a.** Isopropyl alcohol (IUPAC: 2-propanol) is an effective antiseptic. **b.** Many cosmetic products, including lip gloss, contain 1,2,3-propanetriol. **c.** Aircraft anti-icing fluids are about 65 percent 1,2-ethanediol.
Infer ***Why does anti-icing fluid prevent water on the aircraft from freezing at 0°C?***

Differentiated Instruction

L1 STRUGGLING STUDENTS Students may not understand why breaking one bond in a double bond opens up two bonding sites. Have them count the number of bonds each carbon atom can form after the bond has been broken. Remind them that each carbon atom can form single bonds with four other atoms, allowing one atom to be added to each carbon.

ELL ENGLISH LANGUAGE LEARNERS Suggest that beginning and intermediate speakers copy the examples of each reaction type (addition, hydration, halogenation, and hydrogenation) and write a brief native-language explanation beside each type. Encourage advanced speakers to assist students of lower proficiencies with writing their explanations.

L3 ADVANCED STUDENTS Have students research fermentation as a cellular process in animal and microbial cells. Have students design a simple experiment to show that fermentation can take place when the starting ingredient is table sugar (sucrose) rather than glucose.

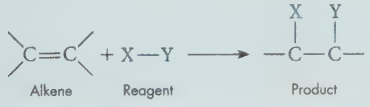
Figure 23.4 Fermentation in Bread
Yeasts, which are part of a bread recipe, break down sugars in the dough mixture. The carbon dioxide gas that is produced diffuses and causes the dough to rise. Tiny holes remain in the baked bread as evidence of the carbon dioxide gas.

Ethanol is an important industrial chemical. Most ethanol is produced by yeast fermentation of sugar. **Fermentation** is the production of ethanol from sugars by the action of yeasts or bacteria. The enzymes of the yeasts or bacteria serve as catalysts for the transformation. The bread in Figure 23.4 rises because of fermentation. Glucose molecules in the dough are broken down by the following fermentation reaction.

$$\underset{\text{Glucose}}{C_6H_{12}O_6(aq)} \longrightarrow \underset{\text{Ethanol}}{2CH_3CH_2OH(aq)} + \underset{\text{Carbon dioxide}}{2CO_2(g)}$$

The ethanol in alcoholic beverages is generally produced by fermentation. Ethanol is an intoxicating substance; it is a depressant that can be fatal if taken in large doses at once.

The ethanol used in many industrial applications is denatured. Denatured alcohol is ethanol that is unsuitable for consumption due to the presence of an additive. That added substance, or denaturant, is often methanol. Methanol is extremely toxic. As little as 10 mL has been reported to cause blindness, and as little as 30 mL has been known to cause death.



READING SUPPORT

Build Study Skills: *Compare/Contrast Table* As you read about addition reactions, use a compare/contrast table to organize the information. In total, three kinds of addition reactions are discussed. Include a column in your table for each kind. ***What do the reactions have in common?***

Addition Reactions

How are addition reactions used in organic chemistry?

The carbon–carbon single bonds in alkanes are not easy to break. In an alkene, however, one of the bonds in the double bond is somewhat weaker. This bond is easier to break than a carbon–carbon single bond. So it is sometimes possible for a compound of general structure X—Y to add to a double bond. In an **addition reaction,** a substance is added at the double or triple bond of an alkene or alkyne. **Addition reactions are an important method of introducing new functional groups to organic molecules. They are also used to convert alkenes to alkanes.** In the general addition reaction shown below, X and Y represent the two parts of the reagent that are added to the alkene.

Explore

Class Activity

Bring household products that contain alcohols to class. Read the name of the alcohol or alcohols given on each label, and help students to write the structure for each alcohol. **Ask** Why do you think alcohols are used in so many commercial products? *(Because alcohols have both polar and nonpolar characteristics, and are capable of forming hydrogen bonds, they make excellent solvents for a wide variety of polar and nonpolar compounds.)*

Teacher Demo

PURPOSE Students will observe the aqueous solubilities of alcohols and glycols.

MATERIALS 10 or 15 test tubes with stoppers, distilled water, ethanol, 1-butanol, 1-hexanol, 1-octanol, a hexanediol

PROCEDURE Prepare two or three sets of 5 test tubes, labeled 1 to 5, each containing a small volume of distilled water and an equal volume of ethanol, 1-butanol, 1-hexanol, 1-octanol, and a hexanediol. Stopper the tubes securely. Instruct students to mix the contents of each tube and allow the mixture to settle. Have students record their observations and describe any trends. Students should generalize about the aqueous solubility of straight-chain alcohols and about the role that —OH groups play in this solubility.

EXPECTED OUTCOMES Students should observe that the solubilities of the alcohols decrease as the alkyl chains increase in length.

UbD Check for Understanding

The Essential Question **What effect does a functional group have on an organic compound?**

Have students summarize their understanding of alcohols by writing or verbalizing a one-minute response to the Essential Question as it pertains to alcohols.

ADJUST INSTRUCTION If students are having difficulty with their summaries, have them reread the section Properties of Alcohols, and then allow them to revise their summaries.

Answers

FIGURE 23.3 A nonvolatile solute depresses water's freezing point.

READING SUPPORT Each reaction results in a product that is more saturated than the reactant.

Explain

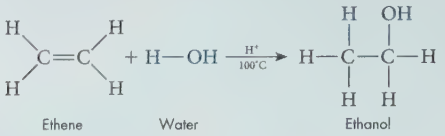
Addition Reactions

USE VISUALS Direct students' attention to Figure 23.5. **Ask** If the orange color remains, what would you conclude about the sample? *(The sample is saturated.)* Remind students that a double or triple bond is more reactive than a single covalent bond. Write the equation for the addition of Br_2 to 2-butene on the board. Explain that when a molecule containing a double bond reacts, one of the bonds in the double bond is broken. This reaction opens up two bonding sites, one on each of the carbon atoms that previously shared the double bond. Explain that the addition of molecules to alkenes makes it possible for chemists to synthesize a large variety of compounds, including polymers.

Explore

TeacherDemo

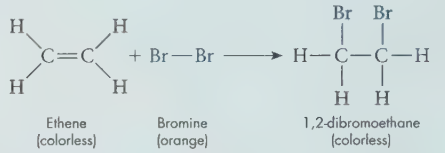
PURPOSE Students will observe the reactions of alkenes and alkynes with oxidizing agents such as potassium permanganate. This reaction can be used to test for unsaturated compounds.



MATERIALS $KMnO_4$, NaOH, distilled water, cyclohexane, cyclohexene, 2 test tubes with stoppers

PROCEDURE Prepare an alkaline solution of potassium permanganate by dissolving 0.1 g $KMnO_4$ and 15 g NaOH in 100 mL distilled water. Put 12 mL cyclohexane in one test tube and 12 mL cyclohexene in a second test t=ube. Add 1 mL of the alkaline permanganate solution to each. Stopper and shake. The general equation for the reaction of permanganate with an unsaturated hydrocarbon is

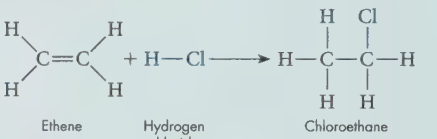
$$RCH{=}CHR + MnO_4^- \rightarrow RCHOHCHOHR + MnO_2$$



EXPECTED OUTCOMES The decolorization of cyclohexene indicates the presence of a double or triple bond. Cyclohexane does not decolorize.

Hydration Reactions The addition of water to an alkene is a **hydration reaction.** A hydration reaction results in the formation of an alcohol. Hydration reactions usually occur when the alkene and water are heated to about 100°C in the presence of a small amount of a strong acid. The acid, usually hydrochloric acid or sulfuric acid, serves as a catalyst for the reaction. The addition of water to ethene to form ethanol is a typical hydration reaction. The parts of ethanol that come from the addition of water are shown in blue in the equation below.

Ethene Water Ethanol



Halogenation Reactions When the reagent X—Y is a halogen molecule such as chlorine or bromine, the product of the reaction is a disubstituted halocarbon. The addition of bromine to ethene to form the disubstituted halocarbon 1,2-dibromoethane is an example.

Ethene (colorless) Bromine (orange) 1,2-dibromoethane (colorless)

The addition of bromine to carbon–carbon multiple bonds is often used as a chemical test for unsaturation in an organic molecule. Bromine has an orange color, but most bromine-substituted organic compounds are colorless. The test for unsaturation is performed by adding a few drops of a 1% solution of bromine in tetrachloromethane to the suspected alkene. As Figure 23.5 shows, the loss of the orange color is a positive test for unsaturation. If the orange color remains, the sample is completely saturated.

Hydrogen halides, such as HBr or HCl, also can add to a double bond. Because the product contains only one substituent, it is called a monosubstituted halocarbon. The addition of hydrogen chloride to ethene is an example.

Ethene Hydrogen chloride Chloroethane

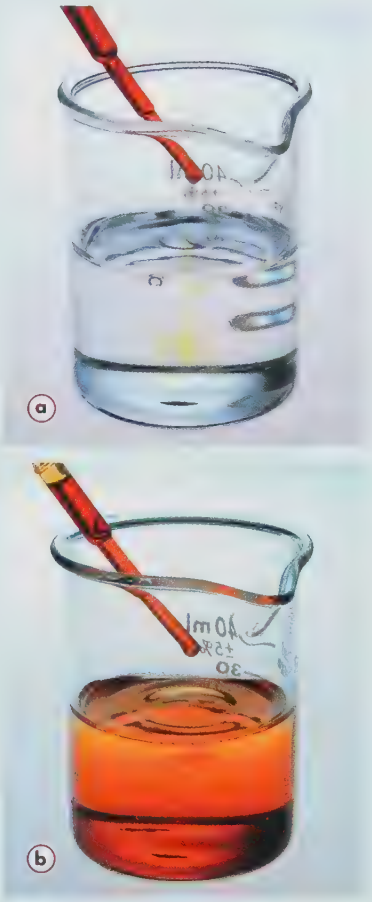


Figure 23.5 Test for Unsaturation
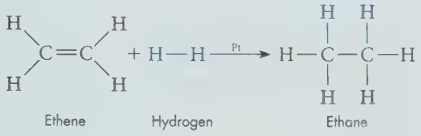
Bromine solution can be used to identify unsaturated organic compounds. **a.** After mixing, if the solution remains colorless, the compound is positive for unsaturation. **b.** If the solution remains orange, the compound is negative for unsaturation.

Professional Development Note

Trans Fats



Trans fats are produced through hydrogenation, the chemical process by which hydrogen is added to unsaturated fatty acids in vegetable oil. Hydrogenation converts the unsaturated bonds in the oil to saturated bonds, creating products such as margarine—a solid, spreadable fat with increased shelf life. Although hydrogenation eliminates some double bonds, it transforms others from the natural *cis* configuration to the *trans* configuration. Research indicates that eating trans fats is associated with an increased risk for heart disease.

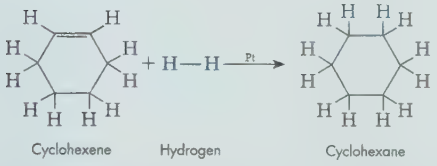


Figure 23.6 Hydrogenation The fats in cooking oils have double bonds. Oils are converted to solid spreads by adding hydrogen to the double bonds.
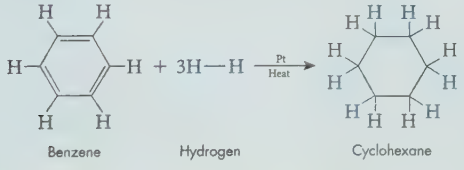
Interpret Photos ***What evidence of a chemical reaction do you see in the photos?***

Hydrogenation Reactions The addition of hydrogen to a carbon–carbon double bond to produce an alkane is called a **hydrogenation reaction.** Hydrogenation usually requires a catalyst. A platinum (Pt) or palladium (Pd) catalyst is often used. The manufacture of margarine or spreads from various oils is a common application of hydrogenation. As shown in Figure 23.6, adding hydrogen to unsaturated fats in oils results in the formation of saturated fats. Saturated fats have higher melting points than unsaturated fats. This is why margarine remains solid at room temperature.



The hydrogenation of a double bond is a reduction reaction. In the examples below, ethene is reduced to ethane, and cyclohexene is reduced to cyclohexane.

See addition reactions animated online.

Under normal conditions, benzene resists hydrogenation. It also resists the addition of a halogen or a hydrogen halide. However, under conditions of high temperatures and high pressures of hydrogen, and with certain catalysts, three molecules of hydrogen gas can reduce one molecule of benzene to form cyclohexane.

UbD Check for Understanding

The Essential Question **How are chemical reactions used in organic chemistry?**

Assess students' understanding of this Essential Question as it relates to addition reactions by asking students to write a one-minute summary explaining how addition reactions are used in organic chemistry.

ADJUST INSTRUCTION If students are having difficulty with their summaries, have them reread the Addition Reactions section and review the figures and associated reactions with them. Point out that in each example, a double bond is being reduced during the reaction. Then, have students revise their summaries.

USE VISUALS Have students examine Figure 23.6. **Ask** What is the difference between a saturated fat and an unsaturated fat? *(Saturated fats consist of carbon atoms saturated with hydrogen atoms, and they are typically solid at room temperature; unsaturated fat is a form of fat that is liquid at room temperatures.)*

CRITICAL THINKING Discuss the health aspects of consuming the various types of fat. **Ask** What is better for you to consume, butter or margarine? Why? *(Sample answer: Margarine is made from vegetable oils, so it contains no cholesterol; butter is made from animal fat, so it contains cholesterol and high levels of saturated fat.)* **Ask** What are the health risks for consuming too many foods high in saturated fats? *(Eating foods that contain saturated fats raises the level of cholesterol in your blood. High levels of blood cholesterol increase your risk of heart disease and stroke.)* Point out that most foods contain several different kinds of fats, including saturated, polyunsaturated, monounsaturated, and trans fats, and that some kinds are better for your health than others. Have students research each type of fat and create a pros versus cons chart in regards to human consumption and health. Ask students to include an example of a chemical structure of each type of fat.

APPLY CONCEPTS Write several examples of addition reactions on the board and help students predict the structure of the expected product in each case.

Answers

FIGURE 23.6 a change in color

Explain

Ethers

CHEMISTRY & YOU Menthol is an alcohol, as indicated by the *-ol* ending in cyclohexanol.

USE MODELS Describe the molecular structure of ethers. Prepare a ball-and-stick or space-filling model to demonstrate that ethers are slightly polar due to the bent geometry around the oxygen atom. Point out that ethers are characterized by a 120° bond angle. **Ask** Are ethers more or less soluble in water than alkanes of similar size? *(Ethers are generally more soluble due to their ability to participate in hydrogen bonding with water.)* **Ask** Would you expect an ether named butyl ether to be symmetric or nonsymmetric? How do you know? *(Symmetric; the prefix di- is often dropped when naming symmetric ethers.)*

APPLY CONCEPTS Discuss the naming of ethers using a number of specific examples. Explain that because ethers contain nonpolar and polar regions and because they are very inert to most chemical reagents, they make excellent solvents for reactions involving nonpolar and polar organic compounds.

CRITICAL THINKING Ask students whether it is possible to have a compound that contains both ether and alcohol functional groups. *(Yes, 4-methoxy-2-butanol is an example.)*

Extend

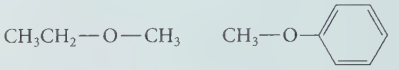
Explain that polyethers are compounds with more than one ether group. In small groups, have students research the structures of polyethylene glycol and polypropylene glycol, the characteristics of each compound, and some important uses of each. Ask students to display their findings in the class.

CHEMISTRY & YOU

Q: *Menthol is the common name of the organic compound responsible for the cooling sensation in many consumer products. Menthol is a cyclohexanol with two alkyl substituents. Is menthol an alcohol or an ether? How can you tell?*

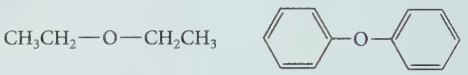
Figure 23.7 Isoflurane
Isoflurane ($C_3H_2ClF_5O$) is a halogenated ether that is used as an inhaled anesthetic. This veterinarian is administering an inhaled anesthetic to a koala.
Observe ***Is isoflurane a symmetric or a nonsymmetric ether?***

Ethers



What is the general formula of an ether?

Another class of organic compounds may sound familiar to you—ethers. An **ether** is an organic compound in which oxygen is bonded to two carbon groups. **The general formula of an ether is ROR.** Like an alcohol, an ether molecule is bent because of the unshared pairs of electrons on the oxygen atom.



Ether

To name an ether using the IUPAC system, first you need to identify the two R groups. The smaller R group is treated as part of the substituent and the *-ane* or *-ene* ending is replaced with *-oxy*. The larger R group is the parent hydrocarbon. In the common names of ethers, both R groups are treated as substituents. The *-ane* or *-ene* endings are replaced with *-yl* for both R groups. To form the common name, list the names of the two R groups in alphabetical order and follow with the word *ether*. Two simple ethers are shown below along with their IUPAC and common names.

Methoxyethane (ethyl methyl ether) — Methoxybenzene (methyl phenyl ether)
